As the advanced wave approaches the horizon of the universe, the velocity of the source relative to the local galaxies approaches the speed of light, and the frequency of the advanced wave increases without limit. Thus, even though the source frequency may be very low, the observed frequency will eventually be shifted above the critical frequency necessary for matter creation.

Since a graviton has zero rest mass, momentum can be conserved during matter creation only by collision

with another particle which can absorb the excess momentum of the graviton. Now McCrea<sup>2</sup>, in an interesting paper, has suggested this postulate: that new matter is created only in the presence of old matter. If matter creation does take place by the action of gravitational radiation, then the conservation of momentum, which we have been at such pains to retain, automatically requires that McCrea's postulate be satisfied.

The most likely spin for a graviton is 2, and so the annihilation of a graviton should result in the creation of four particles of spin  $\frac{1}{2}$ : for example, two protons and two electrons, or perhaps four neutrons. The reverse reaction, in which four particles are annihilated in a collision with a fifth particle to form a graviton, should also be possible. Since this involves a five-body collision, we may expect that this reverse reaction will only take place at extremely high densities, such as are produced by gravitational collapse. In moderately dense matter, we may expect creation to predominate over annihilation.

If, as I have suggested, it is the advanced gravitational wave that is responsible for matter creation, then the matter created will be in the form of anti-particles. This follows from the conservation of momentum.

It is easiest to work in the rest frame of the incoming scattered particle, which then has momentum  $\{0, +im\}$ . Suppose the incoming graviton and the outgoing scattered particle have momenta  $\{p, -ip\}$  and  $\{\beta\gamma m, +i\gamma m\}$ . Then the total momentum of the outgoing created particles will be

$$\begin{bmatrix} p \\ -ip \end{bmatrix} + \begin{bmatrix} 0 \\ +im \end{bmatrix} - \begin{bmatrix} \gamma\beta m \\ +i\gamma m \end{bmatrix} = \begin{bmatrix} p - \gamma\beta m \\ -i(p + (\gamma - 1)m) \end{bmatrix}$$

The created particles thus have negative energy, and so are anti-particles. This at first sight contradicts the elementary observation that the universe consists of ordinary matter, and not anti-matter.

Fig. 1. Doppler shift of advanced and retarded waves

Fig. 2. Emission of anti-particles into the past

However, as Fig. 2 indicates, the created antiparticles are emitted into the past, which is equivalent to the emission of ordinary particles into the future. Presumably the antiparticles will at some point on their world lines be scattered into the future as ordinary particles. In any event, the result is an increase in the net number of ordinary particles towards the future, since antiparticles may be counted as the negative of ordinary particles.

I have suggested that matter may be created by the conversion of gravitational energy into mass energy, without violating any conservation laws other than that of baryon number. However, although on this model energy is conserved locally, it is not necessarily conserved on a cosmic scale. Indeed, on a cosmic scale there is probably no consistent way of attributing energy to a gravitational field. For the energy of a gravitational field is defined by the integral of the energy momentum pseudo tensor over a three-dimensional region which is chosen to be so large that the gravitational field vanishes outside this region. Such a region does not exist if we are considering the gravitational field of the entire universe. There seems to be no reason, therefore, why the total amount in the universe of mass, and of such energy as may be definable, should remain constant—instead, it may fluctuate from epoch to epoch.

Even though this model may perhaps violate the perfect cosmological principle, it still possesses some of the satisfying features of a steady-state model. In particular, it brings the phenomenon of creation within the scope of physical enquiry. Moreover, it does this without introducing any special modifications to terrestrial physical laws. We need not assume that the present laws of physics are inviolate, of course; but in view of its speculative nature, cosmology does not offer a very firm basis for suggesting which of the many possible variations are most likely to be correct.

## GEOPHYSICS

## Continuous Observation of the Auroral Belt by Means of Radio

The purpose of this communication is to show that the southern edge of the auroral belt (the latitudinal range over which aurorae occur at a given time and longitude) can be reliably tracked by radio means. With the multi-frequency high-frequency system used at College, Alaska, the auroral belt can be tracked from overhead at  $65^\circ$  to above  $80^\circ$  north latitude. This wide coverage is possible because the high-frequency system utilizes ordinary ionospheric refraction to extend the northern limit of detection, and normal *H* and *F* layer refraction to produce perpendicularity between the wave and the geomagnetic field. The very-high-frequency auroral radar, on the other hand, can detect only those aurorally associated scatterers located in the *H* layer near the relatively limited region where the line of sight is normal to the geomagnetic field.

sky as the received ultra-high-frequency scatter echoes, and that, furthermore, the amplitudes were proportional. Unfortunately, neither ranges nor heights of the visual aurorae were measured, so these results do not conclusively show that the radio and visual aurorae coincided in space.

Results from the all-sky-camera network north of College, the College and Fort Yukon meridian scanning photometers ( $5577 \text{ \AA}$ ), and the 4-64 Mc/s College step sounder were utilized in the work recorded here. The all-sky-camera photographs and the photometric records were used to determine the position of the auroral belt. From the backscatter records the ranges of the echoes were scaled and converted to latitude by assuming that the slant range of any echo trace equalled the ground distance to the corresponding scattering irregularity. The auroral belt position and the backscatter range results were then plotted versus local time for the 12 days in December 1964, when simultaneous radio and optical data were available; the diagrams for December 7 and 31 are shown in Fig. 1. Cross-hatched areas represent the optically determined

Fig. 1. Optical and radio auroral regions are shown for December 7-8, and December 31-January 1, respectively, in the upper and lower plots. Aurorae are shown as cross-hatched areas, and backscatter irregularities as blocks. Coverage by the optical sites is indicated. Civil (O) and nautical (N) twilight lines are shown.

The precise connexion between radio and visual aurorae is still relatively unknown. The phenomena appear to be closely connected, but, as Chamberlain<sup>1</sup> pointed out in his review of radio auroral work, the relationship is somewhat vague. Leonard, Romick and Belon<sup>2</sup> found that, although the region producing the very-high-frequency radio echoes was grossly associated with that containing the visual aurora, there was no detailed spatial correlation between individual echoes and auroral forms. Using an ultra-high-frequency antenna and a  $5577\text{-\AA}$  photometer with similar beam-widths, Kelly<sup>3</sup> found that auroral light was observed from the same angular portion of the

auroral belt, and solid blocks the backscattering irregularities. The agreement between the optical and the radio data illustrated in Fig. 1 is quite good considering the roughness of the method of scaling the radio data.

The operating optical observing sites and their regions of coverage are shown in Fig. 1 along with the civil (O) and nautical (N) twilight lines up to  $72^\circ$  for the days shown. The December 7 record shows the best agreement of the group while the December 31 record shows one of the poorer examples.

Backscatter echoes frequently arise from discrete sheets located to the north of College and aligned along the

Fig. 2. A typical backscatter ionogram from a discrete E-F sheet. The upward sloping trace was produced by F supported groundscatter

Fig. 3. Four common ionospheric scatter modes observed at College. Modes 1 and 2 are direct E and F scatter, modes 3 and 4 are E scatter which propagate via the F region

geomagnetic field through the E and the F regions<sup>4</sup>. Such a backscatter record is illustrated in Fig. 2. The four most frequently observed high-frequency scatter modes are illustrated schematically in Fig. 3. The method of determining the mode of propagation of a particular echo has been discussed in detail by Bates<sup>5</sup>. Every recorded echo trace other than those from vertical incidence, meteor, groundscatter, and slant F (polar spur) echoes was included in making these plots.

For the 12 days examined, the regions where the backscatter echoes and the aurorae were produced generally coincided. In several instances identifiable backscatter echoes were observed in places where the aurora could not be detected on the all-sky-camera photographs but could be on the appreciably more sensitive meridian-scanning-photometer records. Generally, only the weaker backscatter echoes showed the poor agreement; relatively strong echoes and strong aurorae showed the best agreement. (This may be partly due to the lack of photometric coverage above 71° latitude because much of the lack of agreement occurred between aurorae and echoes produced in the 75°–80° latitudes.) This finding indicates that the backscatter method is apparently sensitive to very weak auroral disturbances.

Normal incidence of the high-frequency energy on the geomagnetic field at any distance is produced by ordinary ionospheric refraction. The high-frequency radar can, therefore, detect an auroral disturbance anywhere from overhead to far beyond the horizon, whereas very-high-frequency and higher-frequency radars can do so only in the limited region where the line-of-sight perpendicularly intersects the geomagnetic field. Thus, the high-frequency system has the considerable advantage of continuous spatial coverage along its magnetic meridian.

The results of this work show that the observed radio-wave scattering region is closely associated with the nighttime auroral belt. No appreciable diurnal difference has been found between backscatter records obtained when the ionosphere was dark or sunlit for a given level of magnetic activity. Thus, the determination of the spatial and temporal variations of the auroral belt is possible from multi-frequency high-frequency backscatter records during daylight hours, and in particular during the Arctic summer, when ground-based optical observations cannot be made.

### The Mohorovičić Discontinuity

THIS distinctive discontinuous layer separates the crust and the mantle of the Earth and extends from 30 km to 50 km below the continents and about 10 km below sea-level in the ocean basins. It has been estimated<sup>1</sup> that this layer has a temperature of 500°–800° C at the base of the continental crust and 150°–200° C in the sub-oceanic discontinuity. This layer is also under a compressive stress of about 10 kilobars (the mean pressure at 35 km is about 10 kilobars) and it has an average density of about 4.0 g/cm<sup>3</sup> as measured by the velocities of seismic waves.

Several theories have been proposed to explain the higher density of this layer in comparison with the density of that just above it, on the basis of (a) a chemical boundary<sup>2</sup>, (b) the gabbro-eclogite phase change or Fermor's theory<sup>3</sup> and (c) the olivine-serpentine reaction as proposed by Hess<sup>4</sup>.

It has been recently reported<sup>5</sup> that a considerably higher density in clay compacts can be achieved if the pressure is present during the decomposition reaction of clays. An extension of this work was carried out to test this effect on some natural rocks and minerals usually present in the Earth's crust. The range of temperatures over which the decomposition or phase transformation occurred for each mineral was determined by the differential thermal analysis technique. In most cases, the temperature of initiation was found to lie between 500° and 600° C. Small powder compacts of these minerals were pressed in a standard hot press using induction heating and either graphite or high-temperature steel dies which functioned both as susceptor and pressing component. The specimens were pressed during the decomposition reaction (first series) and after the decomposition or phase transformation was completed (second series). The final temperatures used in all experiments were above the decomposition temperatures. This was to ensure that the decomposition reaction was completed in a short time. In the first series the pressure was applied from the start of heating, and in the second series the specimens were preheated to the temperature and soaked for about 30 min before the pressure was applied. The materials and experimental conditions used and the results obtained are shown in Table 1.

The most significant difference between this and other investigations is that, in the present case, the decomposition products (water or carbon dioxide) were allowed to escape, whereas in other experiments hydrostatic loading in a closed system was generally used, and this precluded the change of composition produced by the decomposition reaction.

It is quite significant that higher densities can be obtained if the materials are under pressure during the decomposition reaction than if pressed after the decomposition is completed. In all cases, about a 10–25 per cent increase in density was obtained in the first series. In these experiments, however, pressures of about 12,000 lb./in.<sup>2</sup> or less were used. Further experiments were carried out in order to test the effect of increasing pressure on the densification both during (first series) and after the decomposition reaction (second series) of a kaolinitic clay. Fig. 1 shows the final densities of the compacts as a function of the applied pressure for both series. The maximum pressure was limited to 25,000 lb./in.<sup>2</sup> by the experimental

Table 1

Material	Experimental conditions			Results—First series			Results—Second series		
	Applied pressure (lb./in. <sup>2</sup> )	Hot-pressing temperature (°C)	Hot-pressing time (min)	Weight loss (%)	Cold comp. strength (lb./in. <sup>2</sup> )	Bulk density (g/c.c.)	Weight loss (%)	Cold comp. strength (lb./in. <sup>2</sup> )	Bulk density (g/c.c.)
Basalt	10,500	680	10	6.8	6,900	1.96	7.20	200	1.76

Monmorillonite	10,500	650	10	8.5	20,500	2.22	9.00	8,000	2.04
Kaolinite	2,500	650	15	13.6	6,000	1.55	13.6	1,200	1.25

Fig. 1. Bulk density of kaolinitic clay compacts as a function of applied stress

set-up. A change in density from 1.80 to 2.50 g/cm<sup>3</sup> was obtained when the applied pressure was increased from 5,000 lb./in.<sup>2</sup> to 25,000 lb./in.<sup>2</sup> in the first series. On the other hand, in the second series the increase was only from 1.78 to 1.90 for the same increment of pressure.

On the basis of these findings, it is suggested that the higher density of the Mohorovičić layer may be due to the effect of pressure (10–100 kilobars) at the temperatures of decomposition or phase transformation where the natural minerals are unstable and are particularly susceptible to densification.

In drawing any conclusion, however, it should be noted that the density and strength reported here are those measured at room temperature and not those at high temperature and at high pressure. The nature of dense phases that can be obtained if the temperature and pressure are maintained for a very long period of time during the decomposition reaction is still not known and requires further investigation.

RADIOPHYSICS

Latitude Effect on the Variation of Spread-F Occurrence with Sunspot Number

SEVERAL investigators have studied the variation of percentage occurrence of spread-F with sunspot number. Walls<sup>1</sup> reported a decrease in the occurrence of spread-F with increasing sunspot activity at Huancayo. Considering the data for the period 1944–1951, Singleton<sup>2</sup> observed an inverse correlation between the occurrence of spread-F and sunspot number at Brisbane. Kotadia<sup>3</sup> found that at Ahmedabad spread-F occurrence decreases with increasing sunspot activity. These investigators have considered the data taken on all the days (in each month) in their studies. At Ibadan, Lyon *et al.*<sup>4</sup> have shown that spread-F on quiet days reached a maximum value for high sunspot numbers. Recently Rangaswamy and Kapasi<sup>5</sup> studied the variation of spread-F occurrence with sunspot activity in each season taking data for the five quiet days in each month for the period 1957–1962 for Trivandrum, Kodaikanal, Ahmedabad and Yamagawa. At Kodaikanal, a well-defined positive-correlation between the percentage occurrence and the sunspot number was observed by Rangaswamy and Kapasi in all the seasons, while at Ahmedabad a negative correlation was found for summer and a positive one for all other seasons. No definite correlation could be established for the data of Trivandrum and Yamagawa. All these investigators have studied the qualitative aspect of the variation of spread-F occurrence with sunspot number. The purpose of the present investigation was to study quantitatively the dependence of the spread-F occurrence on sunspot number and its variation with latitude by analysing observations from a large number of stations both in the northern and southern hemispheres.

Data from fourteen stations in the northern hemisphere and from eight stations in the southern hemisphere have been analysed. This group of stations is spread over a magnetic latitude range of 88° N. to 57° S. The percentage occurrence of the spread-F from 1800 h to 0800 h for five quiet days in each month has been taken from the published monthly *f<sub>o</sub>F<sub>2</sub>* characteristics. Data for the period 1954–63 have been used, but for certain stations only part of the period has been covered. A twelve-month running average has been taken for the monthly mean percentage occurrence for each station, following the conventional practice, in order to eliminate the seasonal variation. The values thus obtained have been plotted separately for each station against the smoothed observed Zurich sunspot number published in the Central Radio Propagation Laboratory (U.S.A.) bulletins (Part-A).

It has been noticed in all these plots that there is a clear linear variation of mean percentage occurrence of spread-F with sunspot number within a restricted range of sunspot numbers which varies from station to station. In general, the linearity is observed in the sunspot number

Fig. 1 Plot of spread- $F$  variation with sunspot number versus magnetic latitude

range of 40–120. It is found that the slopes of these linear portions vary widely from latitude to latitude, giving both positive and negative values. Positive slopes are obtained for the stations which show positive correlation of mean percentage occurrence of spread- $F$  with sunspot numbers, and negative slopes are obtained with those which show negative correlation. For most of the stations used in this analysis only data for either ascending or descending sunspot cycles are available and, as such, the slopes obtained from either of these cycles are used assuming that there is no difference between the slopes obtained from the ascending and descending cycles for each station. With the view of determining whether there is any systematic variation of these slopes with latitude, the slopes thus obtained from each of the plots of the individual stations have been plotted against geographic, geomagnetic and magnetic latitudes. Of the three plots, the data for the variation of slope with magnetic latitude fit best into a smooth curve (Fig. 1).

Fig. 1 clearly shows that there is a systematic latitude variation of spread- $F$  occurrence with sunspot number. For example, within the low-latitude range of 12° S. to 18° N., the slopes are positive, indicating that, for the low-latitude belt, the spread- $F$  occurrence increases with the increase of sunspot number, the effect being greater for the stations nearer the magnetic equator. The sunspot effect on spread- $F$  seems to be quite prominent for the stations close to the magnetic equator as can be seen from Fig. 1, in which the slope for Trivandrum (Mag. Lat. 0°) stands out prominently from the rest of the surrounding stations. There is a middle-latitude range of about 20°–60° in the northern hemisphere and 12°–45° in the southern hemisphere where the slopes are negative. This means that for all the middle-latitude stations in the ranges specified, the percentage occurrence of spread- $F$  decreases with increasing sunspot number. Furthermore, the slopes attain a maximum negative value for stations situated about a latitude of 40° in the northern hemisphere and about 30° in the southern hemisphere. It may also be seen from Fig. 1 that the sign of the slope changes from negative values to positive values at high latitudes both in the northern and southern hemispheres, the change being more pronounced in the northern hemisphere. It may also be noted that the curve is not symmetrical with respect to the magnetic equator. The results obtained in this investigation are in general agreement with those reported earlier.

## PHYSICS

### The Bath-Tub Vortex In the Southern Hemisphere

It has long been thought that water draining from a tank would rotate counter-clockwise in the northern hemisphere and clockwise in the southern hemisphere, provided other influences were kept small compared with the influence of the rotation of the Earth. This idea has only recently been tested, by Shapiro in Watertown, Massachusetts, as part of a film on vorticity<sup>1-4</sup>, and later by Binnie in Cambridge, England<sup>5</sup>. Shapiro and Binnie both acquired confidence, after surmounting difficulties in their early experiments, that the counter-clockwise rotations observed in their later experiments were due to the rotation of the Earth.

The experiment has now been performed in Sydney, Australia. For this we should like to express appreciation for assistance from the University of Sydney, Tufts University, and the U.S. National Science Foundation.

The apparatus was modelled on Shapiro's. It was a tank, 6 ft. in diameter and 9 in. high, with a central drain pipe 0.375 in. in diameter connected to a draining hose. The tank differed from Shapiro's in ways suggested by early difficulties Shapiro and Binnie experienced. It was made of ply-wood instead of metal, to reduce thermal convection. The drain pipe projected up 1 in. from the bottom, and was tapered to a sharp-edged opening; and the tank was located in a small, cement-walled basement room which had an overhead louvre but no windows, and in which both room temperature and inlet-water temperature remained within a degree of 20° C during the tests. As in Shapiro's experiments, the tank was filled by hose to a depth of about 6 in. above the orifice. The hose was directed so as to leave water swirling counter-clockwise in the tank.

Initially, the apparatus did not work as expected. In the first test, after a 60-h settling period, dust particles on the water surface showed no discernible rotation at any time during an 80-min draining period. This apparently meant that the water was moving to the centre so slowly that the viscous damping effect of the bottom was cancelling the water's angular momentum to the point where no angular momentum was perceptible in the draining fluid. To speed draining, the tank was raised to 30 in. above the floor. From then on, with the increased drop of the draining hose, drainage took about 22 min, and some form of rotation was always observed above the orifice.

Clockwise rotation was observed in all five of the later tests that had settling times of 18 h or more. During the first 10 or 12 min of drainage, no rotation was apparent. Rotation then developed as drainage progressed. In three of these tests a float 0.625 in. in diameter, a slice from a wine cork, was used to indicate rotation. It reached speeds of about one revolution in 8 sec for the runs with settling times of 18 and 20 h, and one revolution in 3 sec

in the one run with a settling time of 70 h. One revolution in 3 sec is what one would expect of a ring of particles rotating with the surface of the Earth at the latitude of Sydney, and then brought in from a diameter of 6 ft. to a diameter of 0.375 in., provided the ring conserves its angular momentum.

To provide a comparison with Shapiro's work, a floating cross made of two matchstick segments 1 in. long was alternated in one test with the cork float. Both cross and float rotated at approximately the same speed. Shapiro used a comparable cross. He reported<sup>3</sup> and filmed<sup>4</sup> rotation speeds of one revolution in about 3–4 sec. His drainage time was also comparable, that is, 20–24 min, and he also reports rotation only after about 10–12 min of drainage.

One early test did not fit the pattern of settling-time influence that emerged later from the tests. The tank, after a settling time of only 4 h 40 min, performed as if it had had 20 h of settling time. Near the end of the drainage period, a 0.5-in. patch of dust particles that had accumulated at the centre was rotating: one revolution in 8 sec, clockwise. This was the only test in which the tank had not been mostly or wholly covered during the settling period. It was an unusually windy day outside, and just before drainage dust specks on different areas of the water surface were moving in several directions at large speeds of about 1 cm/min. The test may therefore have been significantly influenced by air currents. For subsequent tests, the louvre in the ceiling, which had been blocked off, though not completely, by ply-wood sheets, was additionally covered outside with 'Pliofilm'. The door was kept closed, except briefly to allow entry, and the tank was kept mostly covered by two ply-wood sheets resting on two angle irons placed diametrically across the tank. The angle irons were usually spaced about 3 in. apart, so that surface motions could be observed between them, and the direction of these supporting beams in relation to the room was varied from test to test in an attempt to detect any remaining influence of air currents. Air currents did not appear to be a significant influence in the later tests, but it is our opinion that they are likely to have been the largest of the disturbing influences.

In one early test, after a settling period of only 13 h, the no-rotation period was followed by a period of counter-clockwise rotation, which changed to clockwise near the end of the draining period. (In this particular test it is not known how the tank had been filled.) Shapiro reports one similar test, experienced after a settling time of 4–5 h, attributed to undamped initial angular velocity residing in the upper water, while the water nearer the bottom was rotating in the direction of the Earth's rotation. In another of our tests, with a deliberately short settling time of 3 h, water drained out counter-clockwise during all but an initial 2 min of no rotation. Shapiro reports a similar result. In fact, it would seem that the results of these experiments at Sydney are quite similar to those obtained by Shapiro in the northern hemisphere, with one exception. After suitable settling periods, Shapiro observed counter-clockwise rotation. We, in Australia, observed the opposite.

These tests posed for us an unusual problem in experimental work. Normally, one does experiments in which there is some uncertainty in the expected outcome. In these experiments, however, our confidence in the idea that the Earth rotates, and in the applicability of conservation of angular momentum to masses of fluid, was probably so strong that experimental denial would have been almost inadmissible. We should have gone to unusual lengths to get the apparatus to work as expected. Realising this, we found ourselves reluctant to accept as conclusive the results we were getting, results which apparently confirmed our ideas. One can never prove, for example, that it was not some small air current which persistently maintained a circulation that gave the results

we observed, and that a quantitatively comparable, but oppositely directed, air current caused Shapiro's results. There is, in principle, an infinite number of hypotheses that can explain any set of observations. This difficulty in validation of scientific theories is not a new one and, in this instance, as in all instances, it cannot be proved that any one hypothesis is correct. Nevertheless, we have acquired confidence in the hypothesis that carefully performed experiments on liquid drainage from a tank will show clockwise rotation, if done in the southern hemisphere.

## ENGINEERING

### Variation of Breakdown Voltage of a Positive-point/Plane Gap with Applied Voltage Waveshape

In recent years it has become a well-known experimentally observed fact<sup>1–4</sup> that the breakdown voltages of certain non-uniform field gaps are strongly dependent on the shape of the applied voltage impulses. For positive-point negative-plane gaps it has generally been found that, for standard double exponential applied voltage impulses and with gap spacings of 1–5 m, the breakdown voltage decreases with increasing rise-time, for rise-times of 100–200  $\mu$ sec, beyond which it increases again. The magnitude of the effect increases with increase of gap-length and for a 5-m gap, for example, the breakdown voltage at the minimum can be as little as 50 per cent of that for a 1- $\mu$ sec rise-time impulse.

It was suggested<sup>1</sup> that the phenomenon might be due to pre-breakdown corona mechanisms which are dependent on time and could therefore vary with rise-time of any applied impulse voltage. During the discussion on a paper<sup>5</sup> concerning the difficulties of installing a 400-kV grid-system in England and Wales it was suggested that pre-discharge processes occur for slow rise-times and cause the field to become more uniform so that the breakdown voltage increases.

During the course of an investigation of the mechanism of the long spark at CERL the pre-breakdown corona stage was investigated. It was found that the pre-breakdown coronas consisted of pulsed discharges and that the pulses carried considerable quantities of charge. Furthermore, the intervals between pulses clearly indicated that space charge fields resulting from earlier corona pulses affected the development of later pulses. This suggested the following mechanism to explain the experimental observations of the dependence of the breakdown voltage with waveshape referred to above.

For the positive-point negative-plane arrangement the corona discharge propagates across the gap by the following mechanism. An electron occurring within a certain distance of the point causes the initiation of an electron avalanche towards the point. Photons produced by the decay of molecules excited during the avalanche produce more electrons further out from the point. These latter electrons start new avalanches. Thus the corona filaments are built up until the electric field is too weak to allow further avalanche propagation.

The distance from a point electrode at which the field is  $E$ , when the applied voltage is  $V$ , is given by:

$$x = \frac{V}{E} f(D, R) \quad (1)$$

where  $D$  is the electrode separation and  $R$  is the radius of curvature of the point.

For any particular value of  $V$  the maximum distance  $x_0$  from the point at which an avalanche can be initiated, is:

$$x_0 = \frac{V}{E_0} f(D, R) \quad (2)$$

where  $E_0$  is the minimum field in which an avalanche can propagate.

Thus for a filament to propagate across the entire gap the applied voltage has a unique value:

$$V_B = \frac{D E_0}{f(D, R)} \quad (3)$$

from equation (2):

$$\frac{dx_0}{dt} = \frac{f(D, R)}{E_0} \cdot \frac{dV}{dt} \quad (4)$$

Now  $\frac{dx_0}{dt}$  is the speed with which the position of the boundary of the limiting field for avalanche propagation moves away from the point. Also  $\frac{dx_0}{dt}$  is directly proportional to the rate of rise of applied voltage which can be related to the rise-time of the applied impulse if the wave-shape parameters are known. The shape of the experimentally observed curves relating the breakdown voltage and impulse rise-time can be explained in the following manner.

(1) *Short rise-time impulses.* In this case  $\frac{dx_0}{dt}$  is large and therefore the position of  $E_0$  moves very rapidly away from the point. For breakdown to occur an applied voltage is needed of such a magnitude that a field of at least  $E_0$  is produced everywhere within the gap.

(2) *Medium rise-time impulses corresponding to the minimum breakdown voltage.* For a certain slower rise-time  $\frac{dx_0}{dt}$  will be such that in addition to the electrostatic field produced by the applied impulse there will be time for space charge fields to form due to ionization produced in the electron avalanches. Now if the positive space charge drifts across the gap at the same speed as  $\frac{dx_0}{dt}$ , and is just behind the filament tip, the electrostatic field due to the applied voltage will always be enhanced by the space charge field. Thus the field  $E_0$  can be produced by a smaller applied voltage under these conditions than in the absence of space charge. The breakdown voltage will be less than in case (1).

(3) *Slow rise-time impulses.* Beyond the value of  $\frac{dx_0}{dt}$  corresponding to the minimum breakdown voltage the space charge will drift away from the point faster than  $E_0$ . In this case the space charge field will reduce rather than increase the electrostatic field and hence quench the discharge. This inhibiting space charge then has to be removed by the applied field before a discharge can occur. As in (1) the applied field alone has to produce  $E_0$  everywhere in the gap and thus a higher

applied voltage is needed than in case (2). This propagation model is being developed further and it is intended that the complete breakdown process under all conditions will also be included.

## METALLURGY

### Orientation-dependence of Fatigue-accelerated Creep in Aluminium Single Crystals

THE character of some of the creep-fatigue interactions in metals can be extremely complex, as reviews of the subject reveal<sup>1,2</sup>. The fact that creep rates of relatively pure metals, such as lead<sup>3</sup>, copper<sup>4</sup> and zinc<sup>5</sup>, are significantly accelerated by a superimposed fatigue stress is nevertheless well established. A sound explanation for the effect, and its associated features, is not easily advanced without more fundamental information, particularly in respect of the behaviour of single crystals. While some effects in single crystals have been examined (fatigue-activated recovery<sup>6</sup>, for example), no examination of fatigue-activated creep in single crystals appears to have been published so far. The purpose of this communication is to report some initial results derived from experiments on aluminium single crystals in which particular emphasis has been given to the orientation-dependence of fatigue-accelerated creep.

Single crystals of aluminium spark-machined to the specimen shape discussed by Andrade<sup>7</sup> were stressed in a thermostatic enclosure at 180° C by means of an hydraulic device. The experimental assembly enables the static and the alternating components of stress to be controlled and monitored separately, with digital display of the creep strain during a test. The geometry of the specimens also makes it possible to reverse the creep stress direction if required. Crystals of two orientations have been examined. The crystals of one batch were oriented for single slip, and those of the other for double slip, that is, for symmetrical <110> slip on two sets of {111} planes.

The results of the tests on both batches were remarkably similar, and there was no distinctive difference between the behaviour of crystals in the two orientations. A large fatigue-acceleration effect was observed (Fig. 1, curve A), much larger than that which arises from a static stress equal to the peak stress in the cycle (see Fig. 1, curve B), and the hardening introduced was similar to that noted previously in polycrystalline materials<sup>8</sup>; the hardening is manifest by an incubation period of zero creep following the removal of the fatigue stress, with thermal softening eventually bringing about a renewed creep (Fig. 1, curve C). As unexpectedly high values of stress were required to induce measurable creep, the onset of plastic strain in the two orientations as deduced from stress-strain measurements was particularly examined.

The results are summarized in Fig. 2; the differences between the behaviour of the two types of crystal are clearly small and, as with the creep results, no significant distinctions emerge. The possible occurrence of some double slip in the crystals oriented for single slip only

Fig. 1. The creep of aluminum crystals oriented for predominantly single slip, under a static resolved shear stress ( $\sigma_s$ ) of 55 kg cm<sup>-2</sup> and at a temperature of 180° C. The curves are displaced arbitrarily parallel to the strain axis for convenience, the scale being as indicated, and they are not significantly different from those obtained from crystals oriented for symmetrical double slip

Fig. 2. The stress-strain curves of the aluminum crystals in shear, showing the behaviour of crystals undergoing double slip (A) and single slip (B) when stressed in forward and reverse directions. The arrows indicate the amount of creep occurring in 10 min under the respective stresses

cannot be ignored. This seems unlikely, but is being checked.

This particular series of experiments suggests, then, that the acceleration does not necessarily arise from the enhanced activation of cross-slip, that is, from the mechanism primarily responsible for initial fatigue damage. The point-defect generating hypothesis, which associates the acceleration with a more rapid dislocation climb, is not ruled out, but remains unsatisfactory on several counts. We are left with the observation that vibrating dislocations appear to circumvent barriers in their slip planes more easily than statically stressed dislocations, and although the feasibility of this has been commented on previously (for example, by Forsyth *et al.*<sup>9</sup>), a convincing quantitative theory is lacking. The answer may lie in the fact that slip in fatigue-activated creep may be distributed over a band of adjacent slip planes, just as it is in fatigue proper<sup>10</sup>, due to intersections between the primary dislocations and those lying in other slip systems. If the properties of these zones are the key factors, then it remains to explain why these are relatively harder in creep, when stressed statically, than statically-formed

bands are, but effectively softer if an alternating component is present.

## CRYSTALLOGRAPHY

### Preparation of Single Crystals of Barium Azide

THE need for large, optically clear crystals of barium azide of high purity for research studies has been realized for some time. It was first necessary to obtain pure barium azide powder to satisfy the requirements necessary for obtaining optically clear crystals. A method for preparing high-purity barium azide powder was developed at the Explosives Research Laboratory by Reitzner and Manno<sup>1</sup>. In this method, dry gaseous hydrogen azide was made to react with spectral grade barium carbonate in aqueous suspension. Using spectral grade acetone, barium azide was precipitated from this reaction. Table 1 gives the elemental impurities found in BaCO<sub>3</sub> and BaN<sub>3</sub>, in parts per million (atomic) and indicates that even such 'spectroscopically pure' materials contain many impurities. The results of this analysis were obtained from Battelle Memorial Institute by mass spectrographic techniques. An investigation was then undertaken to develop a technique for growing optically clear seed crystals of barium azide from which larger crystals could be obtained.

Spectral grade barium carbonate (Johnson and Matthey) was reacted with dry hydrogen azide gas from the Reitzner-Manno generator:

All reactions were carried out in polyethylene containers to eliminate impurities such as silicon and sodium from glass surfaces. BaN<sub>3</sub> was precipitated at pH 4 with an excess of spectral grade acetone. The water used in the reaction was triply distilled and de-ionized in an ion-exchange column as a purification measure. The material was filtered under nitrogen and placed in a vacuum desiccator over CaSO<sub>4</sub> to dry.

A successful method of obtaining seed crystals of barium azide was to place 50 ml. of saturated BaN<sub>3</sub> solution in water in a 250 ml. graduated cylinder. Three ml. of a 50/50 water/acetone mixture was placed on the surface of this solution by means of a long, thin capillary tube. This procedure prevented immediate precipitation of BaN<sub>3</sub> when acetone alone was placed on the surface. On top of the intermediate layer, spectral grade acetone was added to the 250-ml. mark in the graduate. The graduate was kept at room temperature and was not moved after the acetone layer had been added. Seventy-two hours later, by the diffusion of one liquid into the other, small barium azide monohydrate crystals were precipitated on the surface of the graduate in the water and the acetone levels. Crystals also appeared at the bottom of the graduate. After 10 days, when the crystals had grown to approximately 6.5 mm in length, they were

taken from the solution by siphoning out the liquid. Several dozen seed crystals were obtained from each graduate by this method.

The 6.5-mm seed crystal of  $\text{BaN}_2 \cdot \text{H}_2\text{O}$  was fastened to a glass rod with an adhesive made by dissolving 'Styrofoam' in benzene. Fifty ml. of a saturated aqueous  $\text{BaN}_2$  solution was placed in a 250 ml. graduate and the seed crystal was suspended in the centre of the solution. An intermediate layer of 50/50 acetone/water solution was placed on its surface using the capillary tube. Acetone was then added to the 250-ml. mark and the graduate sealed with a polyethylene-covered rubber stopper. The graduate was kept at room temperature. After five days at room temperature (24° C), the seed could be seen to have grown. Thirty days later the crystal was taken out and found to be 12.10 mm in length.

A saturated  $\text{BaN}_2$  water solution was made and one c.c. of excess water added. The solution was placed in a graduate and the aforementioned crystal placed in its

Fig. 1

Fig. 2

centre. The intermediate layer and precipitating solvent were added as described. After 24 h, a rough surface could be observed on the crystal face as a result of its dissolving in the excess water. Several days later new growth could be observed without a line of demarcation of one growth period on another. After 30 days the crystal was extracted and measured to be 19.05 mm long by 4.76 mm in diameter.

Diffusion is the movement of molecules which in time will tend toward an equilibrium situation in which there are no concentration gradients. With the diffusion technique in the liquid phase, the most abundant crystal habit of barium azide was of the monohydrate variety observed in the water layer (Fig. 1). However, in the precipitating solvent, acetone or alcohol, small square barium azide crystals were observed (Fig. 2)\*. When an ether/alcohol mixture was used as the intermediate layer, clear flat plates of barium azide were observed in the ether/alcohol which may be a new crystal habit.

Slow cooling of saturated barium azide at 55° C in water, water/alcohol, water/methanol, water/acetone, alcohol, methanol, and acetone was found to be an unsuccessful method for the growth of good crystals. These experiments resulted in the formation of a fine powder and some decomposition of barium azide. However, further experiments utilizing these techniques should be undertaken. Slow evaporation of barium azide from water solutions produced large crystals that were in general rough surfaced and uneven. Evaporation from other solvents produced a fine powder and afterwards these techniques were dropped.

I thank Dr. T. Richter, Lieut. P. Marinkas and Dr. P. Kemney for their advice.

### Habit of Triglyceride Crystals

We have examined the habit of purified tripalmitin crystals of the  $\beta$  form grown from the melt and a variety of solvents. The results are summarized in Table 1.

Solvent	Largest face parallel to <i>c</i> axis	Prefereed growth direction	Remarks	Fig. No.
Melt	{110} only	None	—	1
Hexane	100	<i>b</i> Axis	—	2
Benzene	100	<i>b</i> Axis	010 face on most crystals	3
Chloroform	100	<i>b</i> Axis	Large crystals	4
Acetone	{110}	—	Small 100 face visible	5

Figs. 1–5 show typical crystals from each solvent.

Fig. 1. Crystals of tripalmitin grown from the melt ( $\times c. 125$ )

Fig. 2. Crystal of tripalmitin grown from hexane ( $\times c. 170$ )

Identification of the crystal faces is based on measurement of angles and comparison with the work of Vand<sup>1</sup> and Jensen and Mabis<sup>2</sup> for the  $\beta$  form of trilaurin and tricaprln. Tripalmitin may be expected to have a similar structure with a larger *c* axis parameter.

Thicknesses of the crystals along the *c* axis has been measured for a few crystals. This dimension is extremely small for melt grown crystals and relatively larger for solution growth. The crystals grown from acetone were about  $300\mu$  long in the *a*-*b* plane and  $15\mu$  thick along the *c* axis.

The interesting feature of these results is that crystals grown from hexane, benzene and chloroform are elongated in the *b* axis direction and bounded by large 100 faces. Crystals grown from acetone are bounded by {110} faces with small 100 faces sometimes visible and crystals grown from the melt have only {110} faces parallel to the *c* axis.

These observations are consistent with the electron microscope studies of Okada<sup>3</sup> on very small crystals, which also suggest that the crystals grown from ether are similar in habit to those grown from acetone.

Larson<sup>4</sup> has analysed the structure of trilaurin in detail and shown that in the *b* direction there is an

Fig. 3. Crystals of tripalmitin grown from benzene ( $\times c. 28$ )

Fig. 4. Crystals of tripalmitin grown from chloroform ( $\times c. 75$ )

Fig. 5. Crystals of tripalmitin grown from acetone ( $\times c. 150$ )

unusually short intermolecular distance and probably a considerable polar attraction. This evidently results in enhanced growth in this direction when hydrocarbon solvents are used.

Several examples of solvent effects on crystal habit have been reported by Wells<sup>5,6</sup>.

## CHEMISTRY

### An Improved Method of calculating Particle Size Distribution from Centrifugal Sedimentation Experiments

CENTRIFUGAL sedimentation methods are widely used for determining the particle-size distribution of suspensions of fine solids in liquids. Donoghue and Boetock<sup>1</sup>

give methods for calculating the cumulative weight size distribution of a sample from the experimental figures. This method is based on filling the centrifuge with the sample under examination, as opposed to the method initially used by Marshall<sup>3</sup>, and afterwards developed by others<sup>3,4</sup>, in which the sample is introduced as a thin layer superposed on a clear medium of slightly higher density. This latter method is likely to give inaccurate results with some systems due to the phenomenon of 'streaming'. Using the former method, the particle size analysis is performed by running the centrifuge for a given time at constant speed and then measuring the amount of sample which has either sedimented to (or past) a certain radius in the centrifuge, or which remains above this radius. It is immaterial for the purpose of this note which method of measurement is used. The complete size distribution is determined by one of three methods:

(1) The inner radius of the liquid surface and the outer radius of collection are kept constant and samples are collected after varying running times of the centrifuge. (We assume the centrifuge speed is kept constant for all experiments.)

(2) The running time of the centrifuge is kept constant, as is the inner radius of the liquid, and the outer collection radius is varied.

(3) The running time of the centrifuge is kept constant as before, but the outer collection radius is kept constant for successive measurements, while the inner liquid surface radius is varied.

Donoghue and Bostock give methods for calculating the size distribution from experimental data obtained by methods 2 and 3. A simpler and more accurate calculation than that given by these authors exists for method 3 and does not appear in the literature. This can be developed on a physical basis by considering a centrifuge with a collecting plane at radius  $R$ , and filled to a radius  $S$ . We also need to define the speed of rotation of the centrifuge,  $\omega$ , the viscosity of the liquid,  $\eta$ , the density difference between solid and liquid,  $\Delta\rho$ , and the running time of the centrifuge between sample insertion and collection,  $t$ . It is assumed that all these latter conditions are constant. If the inner radius of the centrifuge suspension is decreased by a small amount  $dS$ , then the extra weight of sample introduced into the centrifuge is  $2\pi S T c dS$ , where  $T$  is the thickness of the suspension in an axial direction and  $c$  is the weight of solid per unit volume of suspension. For this extra amount of material added, all that with a particle size larger than a Stokes diameter  $D$  will reach the collecting plane at  $R$ , and all that smaller than  $D$  will be at a smaller radius than  $R$  at the end of the running time  $t$ . This diameter  $D$  is given by the equation:

$$\ln(R/S) = D^2 \Delta\rho \omega^2 t / 18\eta \quad (1)$$

The extra weight of sample deposited at a plane at radius  $R$  due to this change in radius  $dS$  of the top surface of the sample is therefore:

$$dW = -2\pi S T c dS \int_D^\infty f(D) dD \quad (2)$$

The negative sign occurs because the extra added layer causes a decrease in  $S$ . This equation applies to an apparatus where the liquid is run off and the deposited layer is retained for analysis, whereas in the type of apparatus where the over-lying liquid layer is removed for estimation of the weight of solids<sup>3</sup>, the following equation should be used:

$$dW = -2\pi S T c dS \int_0^D f(D) dD \quad (3)$$

In both these equations  $f(D) dD$  is the weight fraction of the sample lying in the size range  $D$  to  $D + dD$ , and hence  $\int f(D) dD$  is the cumulative weight percentage in the

size range stated. It is seen that the cumulative weight percentage can be obtained easily from experiments in which  $S$  is varied but all the other conditions of the experiment are kept constant. Considering equation (3), the weight of sample collected,  $W$ , is plotted against  $S$ , and the tangent to the curve found for varying values of  $S$ . This is divided by  $S(2\pi T c)$ , the bracketed term being a constant for any one sample and apparatus. The resulting figure is the cumulative weight percentage below diameter  $D$ , where  $D$  is related to the value of  $S$  at which the tangent was drawn by equation (1). A similar result can be derived for equation (2).

Equations (2) and (3) can be derived mathematically from the equation for the total weight of material collected, for example, in the case of equation (3):

$$W = \pi T c \int_0^D (R^2 e^{-2\pi D^2} - S^2) f(D) dD, \text{ where } \varphi = \frac{\Delta\rho \omega^2 t}{18\eta} \quad (4)$$

Differentiation of this with respect to  $S$  leads directly to equation (3). Ref. 1 treats the whole problem in terms of the fraction of material in the centrifuge which is collected, rather than the total weight collected, and this results in a much more complicated and less accurate method of calculation. It will be noted that the problem of calculating the size distribution when the radius of collection  $R$  is varied, that is, when equation (4) is differentiated with respect to  $R$ , is not so simple, and hence is less accurate. In this case the method of Donoghue and Bostock is as good as any other.

Donoghue and Bostock also state that no analytical method exists for the derivation of the particle size distribution of a sample when  $t$  is varied. This is correct, though with modern computers iterative methods can be developed for calculating the required results at quite low cost. In our experience this is not as accurate as the method outlined here.

## BIOCHEMISTRY

### Fatty Acid Synthesis in Rabbit Thymus Preparations

IN connexion with our earlier studies on the lipid metabolism in human white blood cells<sup>1-3</sup>, a study on the metabolism of acetate-1-<sup>14</sup>C and malonate-2-<sup>14</sup>C by rabbit thymus preparations was initiated, in order to investigate lipid synthesis in this gland. Information from such experiments does not only apply to the physiological role of the thymus connected with lymphocyte production, but also, eventually, to other functions of this gland<sup>4</sup>.

Two- to three-month-old rabbits were killed by a blow on the head and the thymus immediately excised and chilled in ice. The glands were sliced with a razor and homogenized with 9 volumes of ice-cold 0.25 M sucrose solution in a motor-driven Potter-Elvehjem homogenizer with a 'Teflon' pestle for 1 min. The homogenate was passed through a cheese cloth and separated into two particulate fractions and the particle-free supernatant (Sb), essentially as described previously for human leucocyte preparations<sup>5</sup>. Any floating fat appearing during centrifugation was removed.

The incubation system used in these experiments is shown in Table 1. D(+) biotin was added, as it was shown that in some preparations the addition of 2  $\mu$ moles

Table 1. INCORPORATION OF ACETATE-1-<sup>14</sup>C AND MALONATE-2-<sup>14</sup>C INTO TOTAL LIPIDS OF RABBIT THYMUS PREPARATIONS

	Acetate-1- <sup>14</sup> C		Malonate-2- <sup>14</sup> C
	Incorporation mmoles per mg of protein	Ratio of radioactivity of carboxy carbon to total radioactivity	Incorporation mmoles per mg of protein
15,000g sediment	8.12	1:2.7	7.89
93,000g sediment	17.88	1:3	18.70
8b 93,000g supernatant	Exp. I 49.3	1:2	56.25
" "	Exp. II 7.98	1:2.2	35.40
" "	Exp. III 9.23		18.86

The complete system contained 60 μmoles phosphate buffer (pH 6.5), 0.04 μmoles CoA, 10 μmoles ATP, 1 μmole NADP, 1 μmole NAD, 6 μmoles cysteine, 5 μmoles Mg<sup>++</sup>, 10 μmoles KHCO<sub>3</sub>, 15 μmoles citrate, 2 μmoles biotin, 0.15 μmole acetate-1-<sup>14</sup>C, 5 μmole, or 0.15 μmole malonate-2-<sup>14</sup>C, 3:1 v/v. The volume was 1 ml. and contained 0.2 to 0.5 mg of protein. The flasks were incubated for 1 h. in air atmosphere; at the end of this period total lipids were extracted by the method of Folch *et al.*<sup>1</sup>, and hydrolyzed when needed with methanol hydrochloric acid 5:1 v/v for 7 h at 75° C under nitrogen. The fatty acids which accounted for 95 per cent of the radioactivity of the total lipids were extracted with pentane. Decarboxylation of the free acids was according to the Schmidt reaction, as described by Brady *et al.*<sup>2</sup>.

of it resulted in a maximum incorporation of acetate-1-<sup>14</sup>C. Preliminary experiments showed that CoA and ATP were the absolute requirement of the systems for the incorporation of acetate-1-<sup>14</sup>C by both particulate fractions and Sb, while Mg<sup>++</sup> stimulated the reaction and could replace Mn<sup>++</sup>. A partial requirement for NAD and NADP could be shown for the mitochondria. When Sb was treated with 'Dowex-1 Cl<sup>-</sup>' the system showed a partial requirement only for NADP.

Table 1 shows that both <sup>14</sup>C-precursors are efficiently incorporated into all tested cell fractions. The presented data for malonate-2-<sup>14</sup>C must not be taken as a measure of its rate of incorporation by the various fractions, since part of it may be decarboxylated and incorporated as acetate-2-<sup>14</sup>C, in the presence of ATP<sup>3,4</sup>.

The high percentage of radioactivity found in the carboxy carbon, after decarboxylation of the total fatty acids synthesized from acetate-1-<sup>14</sup>C by the various fractions of the cell, indicates that a large part of this substrate is incorporated through the elongation or mitochondrial system<sup>5</sup>, that is, by direct addition of one or more acetyl-CoA units to pre-existing fatty acyl-CoA units. Since this is a usual finding only for the particulate fractions<sup>6,10</sup>, the operation of the mitochondrial system in the particle-free supernatant must be due either to a peculiarity of the tissue studied, or to an extraction of the system from the particles during the separation procedure. A similar finding has been reported by Christ and Hultmann<sup>11</sup> for rabbit heart and pigeon liver mitochondria. They suggested that the major part of the lipogenic activity is actually present in mitochondria, but is extracted and appears in the centrifugal supernatant. Our data, although they may indicate a release of the mitochondrial system into the supernatant, do not show that the malonyl-CoA pathway system has a mitochondrial origin.

Table 2 shows that both particulate fractions synthesize similar fatty acids, predominantly with a chain-length of

Fig. 1. Autoradiogram of thin-layer chromatogram of total lipids extracted from thymus 93,000g supernatant, incubated with acetate-1-<sup>14</sup>C (I), or malonate-2-<sup>14</sup>C (II). Solvent system: chloroform, methanol, water, 80:20:3 v/v. The abbreviations show the position where the corresponding standards, which were run simultaneously, moved. NL, neutral lipids; U, unidentified; Cr, cerebrosides; PE, PC, PS, phosphatidyl (ethanolamine, choline and serine, respectively); Sp, sphingomyelin.

18, or more, carbon atoms, which are characteristic products of the mitochondrial system<sup>8,10</sup>. The quantitative difference in the fatty acids, formed by Sb from acetate-1-<sup>14</sup>C and malonate-2-<sup>14</sup>C, is consistent with the results of decarboxylation and indicates that not all acetate-1-<sup>14</sup>C is incorporated via the malonyl-CoA intermediate. It should be mentioned here that results reported for the Sb of other tissues<sup>8-9,12-15</sup> show that malonate is mainly incorporated into palmitate. In contradiction to the foregoing, in the Sb of thymus, malonate is almost equally incorporated into myristate and palmitate. We have no explanation at the moment for this high rate of myristate synthesis.

Fig. 1 shows that when Sb from the same preparation was incubated with acetate-1-<sup>14</sup>C (U<sub>1</sub>) or malonate-2-<sup>14</sup>C (U<sub>2</sub>), the radioactivity was mainly associated with one

† Dashes indicate that the compounds were trapped with the C<sub>14</sub>.

Fatty acids, extracted as described in Table 1, were methylated and separated by preparative gas liquid chromatography on a Pye argon chromatograph as described previously<sup>12</sup>. Standard fatty acid esters were added routinely for identification.

fast-moving spot, which moved to different positions, depending on the precursor used. In addition, it was shown that by mild alkaline hydrolysis and silicic acid chromatography<sup>10</sup>, when Sb was incubated with acetate-1-<sup>14</sup>C, only 10–30 per cent of the labelled fatty acids were linked in ester bond to the complex lipid, whereas the opposite was true when malonate-2-<sup>14</sup>C was used as substrate. It is unlikely that the differences in fatty acids synthesized from the two precursors account for the observed difference in their utilization. Therefore, further experiments are now in progress, to elucidate the structure and significance of these lipids, which are resistant to mild alkaline hydrolysis.

### Role of Cysteine in the Production of Fc and F'c Sub-components of $\gamma$ G Myeloma Globulins

RECENTLY, Osserman and Takatsuki<sup>1</sup> have described a group of  $\gamma$ G myeloma proteins the Fc fragment of which was completely destroyed by the action of papain. A similar protein (myeloma N) was independently examined in this laboratory. This protein was found to be susceptible to papain and trypsin<sup>2</sup>.

Immunological typing has characterized this protein as shown in Table 1. The Zu (ref. 3), V<sub>4</sub> (ref. 4) and  $\gamma$ 2c (ref. 5) groups denote different terms for a similar antigenic determinant. All enzyme-susceptible Fc fragments so far belong to this group. The results of Grey and Kunkel<sup>4</sup> indicate that monkey anti-Zu, but not rabbit anti-V<sub>4</sub>, develops an Fc component on immunoelectrophoresis. This would suggest that a more heterogeneous group of proteins is found in this H chain sub-group.

Some of the factors which might be involved in this susceptibility were now examined. Oebra *et al.*<sup>3</sup>, using a water-insoluble papain derivative, have shown that cleavage of rabbit  $\gamma$ -globulin is a two-stage process. The initial stage of the reaction involved the splitting of some peptide bonds by papain, and the subsequent reduction of the products into smaller fragments by cysteine. Hsiao and Putnam<sup>7</sup>, using mercurypapain, have shown that proteolysis of human  $\gamma$ -globulin in the absence of cysteine results in the liberation of 3.5S fragments, and a variable amount of 6.6S material. Accordingly, the role of cysteine in the proteolysis of myeloma N was examined. In our experiments, papain digestion (crystallized papain  $\times 2$ , lot No. 5575, Worthington

Biochemicals), in the absence of cysteine, was conducted in 0.1 M phosphate buffer, pH 6.0 at 37° C at a protein to enzyme concentration of 100:1 for 18 h. The immunoelectrophoretic patterns in Figs. 1a and c show the production of an Fc-like but not F'c fragment under the foregoing described conditions. The incorporation of 0.01 M cysteine into the digestion process results in the production of both the Fc and F'c precipitin bands in human  $\gamma$ G (Cohn Fr II) (Fig. 1b), but in the destruction of both these fragments in the case of myeloma N (Fig. 1d). Ultracentrifugal analysis has shown that under the former conditions, myeloma N protein digested with and without cysteine yields only 3.5 S fragments. Under similar conditions in the absence of cysteine, human  $\gamma$ -globulin and papain insensitive  $\gamma$ G myelomas yield products sedimenting at 3.6 S (80 per cent) and 6.7 S (20 per cent).

A large number of  $\gamma$ G myelomas and human  $\gamma$ G (Cohn Fr II) were studied with the aid of starch-gel electrophoresis after papain digestion. The Fc component of these proteins resolves into a series of bands which are identical as to concentration, number and migration. The sub-units of the Fab fragment are specific for each  $\gamma$ G myeloma on starch-gels.

Fig. 2 comprises human  $\gamma$ G (Cohn Fr II),  $\gamma$ G myeloma T (papain insensitive) and  $\gamma$ G myeloma N (papain sensitive) digested by papain with and without cysteine. Figs. 2A and B, respectively, show the typical distribution of Fc sub-components of human  $\gamma$ G and T myeloma proteins digested in the presence of cysteine. There are at least 9 bands of which No. 6, counting from the application slot toward the anode, stains the most intensely. C and E represent, respectively, similar proteins digested in the absence of this sulphhydryl agent. It can be seen that the number, migration and intensity of the Fc sub-components are the same, but differ from those of A and B. In contrast, D and G, respectively, show myeloma N cleaved without and with cysteine. Complete dissolution of the Fc sub-components is seen in Fig. 2G. The Fc fragment and its sub-components, which are only produced in the absence of cysteine (Fig. 2D), show no similarity to those of myeloma T or myeloma N, and human  $\gamma$ G similarly treated. In Figs. 2B and C, several bands can be seen on the anode side of the application slot. These have a similar rate of migration to native myeloma protein T (Fig. 2I) and may be identical. It is suggestive of the 6.7 S sedimenting material seen in the digests of myeloma T treated without cysteine.

The four bands in Fig. 2D, and to a lesser extent in Fig. 2G, which migrate slightly to the cathode side of the application slot, have a mobility similar to native myeloma

Fig. 1. Immunoelectrophoretic analysis of human  $\gamma$ G (Cohn Fr II) and myeloma N protein after digestion with papain in the presence and absence of cysteine

a, b, Human  $\gamma$ -globulin; c, d, myeloma N; a, c, digested without cysteine; b, d, digested with cysteine. Precipitin arcs were developed with a rabbit antiserum containing antibodies directed against the Fab, Fc, and F'c fragments

Fig. 2. Starch-gel electrophoresis of human  $\gamma$ -globulin (Cohn Fr II) and  $\gamma$ G myelomas (T and N) after digestion with papain in the presence and absence of cysteine. Human  $\gamma$ -globulin: A, F, cysteine present; B, cysteine absent; J, native protein. Myeloma T: B, cysteine present; C, cysteine absent; I, native protein. Myeloma N: G, cysteine present; D, cysteine absent; H, native protein. Fab, Fc and Fc' fragments are indicated.

protein N (Fig. 2H). Although no 6.8 S sedimenting component was seen in myeloma N treated without cysteine, this may be no more than due to concentration. In determining Svedberg constants, 0.4 per cent solutions were used as opposed to 5 per cent on the gels.

Another difference in the patterns obtained with and without cysteine in the papain digestion mixture is seen in the Fc' region. All materials digested in the absence of cysteine (Figs. 2C, D and E) are characterized by the lack of the Fc' fragment in contrast to proteolysis with cysteine (Figs. 2A, B and F) where the three typical Fc' bands appear. These observations were also confirmed by immunoelectrophoresis (Fig. 1).

Table 1. PROPERTIES OF  $\gamma$ G MYELOMA N

Physico-chemical		
$S_{20}$	6.85	
Solubility	75% soluble in saline at 1% w/v	
Sludge content	0.16% dry weight	
Mobility—agar	$\gamma$ G	
Starch (tris buffer)	Cathode	
Immunological		
	H chain	L chain
Antigenic type	Vi ( $\gamma$ 2, 2a)	K (I)
Genetic allotype	Gm (a-b-*) (a-)	Im V (a-b-)

\* The Gm(b) group was negative at 0.25 mg/ml, but positive at 5 mg/ml.

In summary, it should be noted that the number and position of the Fc' and Fc fragments of human  $\gamma$ G and papain insensitive  $\gamma$ G myelomas are characteristic for each mode of papain digestion. When proteolysis occurs in the presence of cysteine, the Fc' bands evolve and a distinct set of Fc sub-components is separated on starch-gel. However, when digestion occurs in the absence of cysteine, the Fc' sub-components do not appear and a new set of Fc sub-components is demonstrated. For each mode of digestion, the Fc' and Fc sub-components are identical in all the papain insensitive  $\gamma$ G myelomas and human  $\gamma$ G (Cohn Fr II) thus far tested.

A unique  $\gamma$ G myeloma protein has been described where the integrity of the Fc and Fc' sub-components depends

on the presence or absence of cysteine during digestion. The Fc sub-components of myeloma N can be produced by cleavage in the absence of this sulphhydryl compound, and the separated Fc sub-components show a different distribution from those described here. Short periods of digestion (less than 1 h) can also result in production of an Fc precipitin arc. The Fab component typifies each myeloma protein, and its pattern on starch-gels is independent of the action of cysteine, suggesting the primary action of this agent is on the Fc fragment. From the practical point of view one is now able to isolate an Fc fragment of papain-sensitive myelomas for further investigation.

From the aforementioned experiments, it appears that cysteine acts on some crucial disulphide bond(s) which may unfold or denature the Fc intermediates<sup>1</sup>, making the latter more susceptible to papain.

### Specificity of Pigment Formation by *Penicillium rubrum* Stoll

THOUGH *Penicillium rubrum* Stoll can often be isolated from mould growth on organic substance and is, indeed, very widely distributed, the appearance of the red pigment at the site of the growth, which is one of its important characteristics, is not at all frequent. This fact suggests that some strict specificity exists in pigment formation by *P. rubrum*. During a preliminary study<sup>1</sup> on pigment formation by *P. rubrum* Stoll, interest was aroused by the fact that while a number of hexoses and pentoses, providing a source of carbon, gave good pigment formation, a few of them invariably failed to produce the pigment, although they served the nutritional requirements of the mould equally well. Experimental evidence indicates that the source and quantity of nitrogen, within wide limits, had no effect on pigment formation nor was it dependent on the presence of trace elements. That pigment formation was closely connected to some specificity of the saccharide molecules used as the carbon source in the culture was evident from such observations.

A close scrutiny of the conventional molecular structure of saccharides used in this study and their effect on pigment production by *P. rubrum* (Table 1) suggests that the configuration of the saccharide molecules themselves is significant and that only those hexoses and pentoses having a core of HCOH at the 4-carbon and 2-carbon respectively, taking the carbon core of D-glucose as standard, are able to produce the pigment, no matter whether they are of D- or L-variety. This obviously suggests that the formation of some specific intermediate in the biogenic pathway of the pigment synthesis is strictly dependent on the core configuration of the 'sugar' molecule.

Table 1. PIGMENT PRODUCTION BY *P. rubrum* IN MEDIUM CONTAINING 1.0 PER CENT (W/V) BACTO-PEPTONE AND 2.0 PER CENT (W/V) 'SUGARS' pH 5.3

'Sugars'	Pigment production (O.D.) 20 days	Structural characteristics
Monosaccharides

L-Arabinose	0.434	H-C-OH

O.D. = Optical density (measured in 1:1 dilute culture filtrate).

\* Taking the core at 4-carbon atom in D-glucose as standard.

It is known that one of the biogenic pathways to aromatization from glucose and similar compounds is through the quinic acid-dehydroshikimic acid-shikimic acid system<sup>2</sup>. To investigate whether such a pathway also existed in aromatization to pigment formation, cultures in peptone-glucose, peptone-galactose, alanine-glucose and alanine-galactose were periodically tested for quinic acid and shikimic acid chromatographically<sup>3</sup>. A yellow spot on the paper corresponding to quinic acid in position and  $R_f$  value was obtained with glucose media but not with galactose. Any spot corresponding to shikimic and dehydroshikimic acid was, however, absent in either case. The observation of quinic acid alone and not shikimic dehydroshikimic acid in glucose media became conspicuous for the fact that quinic acid, by itself, is not considered to be in the line of direct aromatization, but it can only do so through the dehydroshikimic and shikimic acid system<sup>4</sup>. Therefore the possibility of quinic acid being formed as a casual metabolite instead of an essential intermediate could not be ruled out, and it was considered pertinent to investigate whether the addition of quinic acid to a culture

Table 2. PIGMENT PRODUCTION BY *P. rubrum* IN MEDIA CONTAINING  $\beta$ -ALANINE (0.5 PER CENT W/V) AS THE SOLE NITROGEN SOURCE AND QUINIC ACID OR GLUCOSE AS THE ONLY OTHER INGREDIENT. pH 5.3

Media	Pigment production (O.D.) in days		
	12	18	24
$\beta$ -Alanine + glucose 2.0% (w/v)	0.000	0.066	0.068

$\beta$ -Alanine + quinic acid 1.0%	0.116	0.256	0.450
$\beta$ -Alanine + quinic acid 0.5%	0.062	0.152	0.446
$\beta$ -Alanine + quinic acid 0.25%	0.022	0.062	0.270

Optical density (O.D.) was measured in 1:1 diluted culture filtrates.

could produce the pigment which was otherwise negative. This would establish the intermediate role of quinic acid as well as of conditions prevailing in the culture for its conversion to pigment. Results obtained in this direction are recorded in Table 2.

The fact that in a chemically defined medium quinic acid can supplement glucose, or can itself act as the carbon source for pigment production, sufficiently indicates the role of quinic acid as an intermediate in the biogenesis of this pigment. It was further confirmed spectrophotometrically that in all cases, either with saccharides or with quinic acid, the same pigment was produced (Fig. 1 A and B).

Identification of a compound as an intermediate in microbial metabolism, or in the biogenesis of a particular end-product, depends on the detection of the supposed intermediate in the culture and the ability of the inter-

Fig. 1. Absorption curves of the pigmented culture filtrates. Media A, Bacto-peptone 1.0% (w/v), 'sugars' 2.0% (w/v). B,  $\beta$ -alanine 0.5% (w/v), quinic acid 0.5% (w/v) or glucose 2.0% (w/v). The absorption maxima of the pigmented cultures were read in a spectrophotometer at wave-lengths between 400 and 600 m $\mu$  in 10-mm cells.

mediate to support the growth of the organism to give the particular end-product<sup>1</sup>. The fact that quinic acid has been detected in the mould culture in peptone-glucose and alanine-glucose media prior to pigment formation, and that quinic acid by itself as the carbon source can form the pigment in medium containing  $\beta$ -alanine as the only other ingredient, unequivocally shows that the pathway to this pigment formation is through quinic acid.

The biogenesis of pigment in *P. rubrum* Stoll, as observed here, does not reveal the complete pathway but does indicate that quinic acid is one of the essential intermediates in the process and that, once it is available in the required concentration, pigment formation becomes a normal sequence to it. The evidence suggests that the structural specificity of the saccharides is the main determinant of quinic acid formation and consequently of production of the pigment.

I thank Dr. Y. Nayudamma, the director, for his interest, Drs. D. Ramaswamy and K. N. S. Sastry for spectrophotometrical data and detection of quinic acid, and Mr. E. C. George for chromatographic analyses.

### Glucose Space of the Corn Scutellum

SLICES of the corn scutellum (*Zea mays* L., var. 'Tunka G-76') do not accumulate glucose although they take up glucose from a glucose solution at an appreciable rate<sup>1</sup>. Our results indicate that the scutellum tissue contains an intracellular glucose space the glucose content of which is in equilibrium with the bathing solution. Glucose space is defined as the volume of tissue water necessary to contain the glucose of the tissue at the concentration of the bathing solution<sup>2</sup>.

Slices (0.5 mm or less in thickness) were prepared from scutella obtained from 3-day-old, etiolated seedlings. To determine the glucose content, the slices were washed on a Buchner funnel for 2 min with cold water (1°-2°) and then extracted with boiling 80 per cent ethanol. After removal of the ethanol, the extracts were taken to volume with water, cleared with  $ZnSO_4$  and  $Ba(OH)_2$ , and analysed for glucose by the glucose oxidase method ('Glucostat', Worthington Biochemical Corp., Freehold, N.J.).

The slices took up glucose at a maximum rate of about 70  $\mu$ moles/h/g fresh weight. This rate was obtained at a glucose concentration of 0.1 M in the bathing solution. At this concentration the glucose space contained only about 8  $\mu$ moles of glucose and thus it contributed very little to the net uptake (Fig. 1). The presence of  $5 \times 10^{-4}$  M 2,4-dinitrophenol (DNP) in the bathing solution inhibited net glucose uptake by 80 per cent. However, DNP caused a doubling of the glucose space (Fig. 1). Mannose (0.1 M) also inhibited net glucose uptake<sup>3</sup> and increased glucose space (to 0.16 ml.). The mannose results (not shown in Fig. 1) were similar to but fell slightly below the results with DNP. The size of the glucose space was independent of the glucose concentration of the bathing solution in the range of 0.1-0.3 M when DNP or mannose was present. In the absence of these compounds the glucose space decreased slightly when the concentration of glucose in the bathing solution was below 0.2 M (Fig. 1). The glucose space made up 12 per cent of the tissue water when the tissue was incubated in glucose alone, 24 per cent when the slices were incubated in glucose + DNP, and 20 per cent when the slices were incubated with glucose + mannose. Finkelman and Reinhold, using segments of sunflower

Fig. 1. Glucose content (○) and glucose space (●) of the scutellum slices as a function of the glucose concentration of the bathing solution. The slices were incubated (1 h, 30°) in glucose (bottom two lines) or glucose plus  $5 \times 10^{-4}$  M DNP (top two lines).

hypoocotyls, found that DNP brought about an increase in the apparent free space both for fructose and inulin<sup>4</sup>.

The movement of glucose into the glucose space was rapid, and equilibrium with the bathing solution was reached within 30 min (Fig. 2A). In the absence of DNP or mannose (which inhibit glucose utilization), measurement of the glucose content of the slices as a function of time indicates the rate of glucose build-up in the glucose space, not the net rate of glucose movement from the bathing solution. This is apparent from the fact that

Fig. 2. A, Tissue glucose as a function of the incubation period in 0.15 M glucose +  $5 \times 10^{-4}$  M DNP (curve 1), 0.25 M glucose (curve 2) and 0.15 M glucose + 0.1 M mannose (curve 3). B, Effect of temperature on the movement of glucose from the slices into the bathing solution. Slices (1 g) were placed in 0.1 M glucose +  $5 \times 10^{-4}$  M DNP for 1 h. At the end of this period the slices were filtered out and washed on a Buchner funnel with cold water (1°-5°) for 2 min, and then placed in flasks containing a  $5 \times 10^{-4}$  M DNP solution at either 30° or 1° C. The glucose content of the bathing solution was measured at the times shown. The arrow indicates the time at which the temperature was raised from 1° to 30°.

glucose was being utilized by the slices at a rate exceeding 1  $\mu$ mole/min. The rapid rate of glucose utilization probably accounts for the break in the tissue glucose curve of Fig. 1.

Since DNP inhibited glucose utilization and increased the glucose space, it was used in the study of the movement of glucose from the slices into the bathing solution. Slices were incubated with glucose and DNP to fill the glucose space. The slices were then washed and placed in DNP and the movement of glucose into the bathing solution was measured as a function of time at two temperatures (Fig. 2B). At 30° the glucose of the slices rapidly equilibrated with the bathing solution, but at 1° there was only a slow movement of glucose into the bathing solution. The effect of temperature on the movement of glucose out of the slices indicates that there is a barrier to free diffusion. Presumably, therefore, the glucose was intracellular.

Fructose, mannose, methyl-D-glucose, glucosamine, N-acetyl glucosamine and mannitol did not inhibit the entry of glucose into the glucose space. Fructose and mannose occupied a space of similar size to that for glucose. Mannitol, which was metabolized by the slices at very low rates if at all, also entered a space similar in size to that for glucose. These results do not indicate that the movement of glucose into the glucose space is carrier-mediated.

We thank Mr. Parviz Bolourtchi for his assistance. This research was supported, in part, by a grant, AM 07299-02, from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service.

### Surfactant Lipids of Plant Quantasomes

THE plant sulpholipid, 6-sulpho- $\alpha$ -D-quinovopyranosyl-(1 $\rightarrow$ 1')-2',3'-di-O-acyl-D-glycerol, has been found in all photosynthetic organisms so far investigated<sup>1-3</sup> and only in such organisms. Although its biological role and its localization in photosynthetic tissues have not been experimentally elucidated, the observed relation between its occurrence and photosynthetic activity suggested a possible relation between this surfactant lipid and plant photosynthesis<sup>4</sup>.

We have now demonstrated that the sulpholipid and the lysosulpholipid<sup>5</sup> of *Lemna* are specifically concentrated in the quantasomes, the particle fraction of chloroplast first demonstrated by Park and Pon<sup>6</sup> to be responsible for the light reactions of plant photosynthesis.

*Lemna perpusilla* 6746, uniformly labelled with <sup>14</sup>C or <sup>35</sup>S, was prepared by growing it in a mineral medium<sup>7</sup> under photosynthetic conditions with <sup>14</sup>CO<sub>2</sub> or <sup>35</sup>SO<sub>4</sub><sup>2-</sup> for 3-7 days. We used *Lemna*, a small aquatic plant with leaves 1-3 mm long, as supplies of chloroplasts and various subcellular components could be easily prepared and labelled with radio-isotopes. Micro-analyses of components were made by radiochemical techniques.

Preliminary experiments with the chloroplasts isolated from *Lemna* uniformly labelled with <sup>14</sup>C revealed the virtual absence of major glycolipids, sulpholipids and galactolipids<sup>8</sup> in both the membrane (14,000g pellet) and the 145,000g supernatant fractions of sonically ruptured chloroplasts. Since most of the glycolipid content was found in its 145,000g pellet fraction, the latter could be deemed to represent whole chloroplast as far as the glycolipid content was concerned.

<sup>35</sup>S-labelled *Lemna perpusilla* was gathered by filtration and washed with 0.1 M potassium phosphate, pH 7.4. The whole plant was well ground in a chilled mortar with a small amount of the same buffer, and disintegrated by sonic oscillation at 9 kc/s for 2 min. The sonicate was centrifuged at 14,000g for 10 min, and the pellet was re-suspended in the same phosphate buffer and centrifuged at 14,000g for 10 min. This re-suspension of the pellet and centrifugation were further repeated twice. The pellet (14P) became completely colourless. The combined supernatant was centrifuged at 145,000g for 30 min. The pellet was washed once in water and collected by re-centrifugation (145P). This dark-green pellet should have contained all quantasomes of the starting plant tissues. The supernatant (145S) was completely colourless.

Each fraction was analysed by two-dimensional chromatography on Tōyō No. 51 paper, first in phenol-water (500:180 w/w), and then in *n*-butanol-propionic acid-water (142:71:100 v/v/v)<sup>9</sup>; afterwards autoradiograms were prepared. The sulpholipid content was determined by measuring the radioactivity of corresponding spots with a Type 5006 Geiger-Müller tube (Nihon Musen Co., Tokyo). Table 1 demonstrates that the sulpholipid and the lysosulpholipid are practically absent in the two colourless fractions and are specifically concentrated in the quantasome fraction which represents the major part of the lamellar structure of the chloroplast and is responsible for the light reactions of photosynthesis<sup>6,10</sup>.

Table 1. DISTRIBUTION OF THE SULPHOLIPIDS IN *Lemna perpusilla*<sup>35</sup>S

		14P	145S	145P
Sulpholipid	<sup>35</sup> S c.p.m.	570	1,980	23,800

	Per cent	0	6	94

A quantasome preparation isolated from non-labelled spinach leaves by our method was analysed for its chemical composition. The results shown in Table 2 indicate the lipoprotein-like nature of the preparation. Amino-acid composition of the protein moiety was studied and was compared with those of average plant proteins: somewhat higher contents in neutral amino-acids and lower in basic acids were observed.

§ Hot perchloric acid-insoluble fraction minus protein.

¶ Calculated from the optical density at 260 m $\mu$  of hot perchloric acid-soluble fraction.

The plant sulpholipids are the only lipids so far described the occurrence of which is limited to tissues with one common biological activity—photosynthesis. The present findings that the sulpholipid and the lysosulpholipid are specifically located in the quantasomal or lamellar part of the plant cells further suggest the importance of the role of these surfactant compounds in the photosynthetic reactions of plants.

Preliminary experiments revealed that two galactolipids, galactosyl diglyceride and digalactosyl diglyceride<sup>8</sup>, are also concentrated in the quantasomes, whereas phospholipids and triglycerides are rather rich in other fractions, suggesting different biochemical roles for these lipids in plants.

The quantasome preparations described here may be contaminated by non-chloroplast components such as mitochondria and ribosomes. The possibility that such con-

terminating particles contain a considerable proportion of the sulpholipids is, however, very small, since our preliminary studies showed the absence of the sulpholipids in isolated mitochondrial as well as in ribosomal fractions.

We thank Dr. M. Miyano and Mr. C. S. Chen of this Institute for their assistance in the cultivation of *Lemna*.

## PHYSIOLOGY

### Release of Acetylcholine from a Nerve Terminal by Electric Pulses of Variable Strength and Duration

It has recently been shown<sup>1</sup> that the release of acetylcholine from a motor nerve ending does not occur immediately when the action potential arrives at the terminal, but starts after a delay of about 0.5 msec at 20° C (and considerably later at lower temperatures<sup>2</sup>). To find out more about the relation between the electrical changes in the nerve ending and the subsequent secretion of the transmitter substance, it is desirable to apply graded electric pulses locally to the presynaptic terminal. This has been difficult to achieve because above a certain strength a locally applied depolarizing pulse initiates an all-or-none impulse in the terminal<sup>3</sup>. To overcome this difficulty we have used the substance tetrodo-toxin which is known to abolish impulses in nerve and muscle fibres

Fig. 2. Relation between duration and strength of equally effective pulses. The duration (abscissa) was varied, and the current intensity (relative units along the ordinate) was determined which caused occasional unit responses to appear at the end of the pulse. The lowest current strength (20 msec pulse) was approximately 0.15 mamp. Temperature 20° C.

without blocking the depolarizing action of acetylcholine on the end-plate<sup>4</sup>. Quite recently, Elmquist and Feldman<sup>5</sup> showed that the spontaneous miniature end-plate potentials (m.e.p.p.'s)—which are indicative of an intermittent spontaneous secretion of packets of acetylcholine from the terminals<sup>6</sup>—are not affected by tetrodo-toxin, and that their frequency can be raised, much as in a normal preparation, by increasing the external potassium concentration. Thus, tetrodo-toxin has the remarkable property, unlike other blocking agents such as curare or procaine, of paralysing the nerve and muscle fibre while leaving the special properties of the neuromuscular junction unimpaired.

The following experiments were made on frog sartorius and rat diaphragm muscles immersed in tetrodo-toxin at a concentration of  $1-4 \times 10^{-6}$  g/ml. (about a hundred times more than required to block the motor nerve impulse). Under these conditions, brief negative-going pulses applied through a micropipette (2-4  $\mu$  tip) to the surface of a nerve terminal evoked end-plate potentials which were recorded with an electrode inside the muscle fibre (Fig. 1). The response had the well-known quantal character: that is, it was composed of a fluctuating whole number of m.e.p.p.'s. With less than a certain intensity of the applied pulse, no response was observed. As the pulse strength was raised, single m.e.p.p.'s appeared in an all-or-none manner, their average number growing gradually as the intensity of the applied pulse was further increased. Similar effects were observed when the strength was kept constant and the duration increased. Finally, a 'strength-duration' curve could be obtained for a constant size of response, as in Fig. 2, showing the relation between length and intensity of equally effective depolarizing pulses. The experiments showed that depolarizations lasting no more than 100  $\mu$ sec (which is much shorter than the action potential) can be effective in releasing acetylcholine, provided they are made strong enough.

A point of particular interest was the time relation between the pulse and the commencement of the response. It has previously been shown that the start of the e.p.p. can be taken as a fairly accurate signal of the instant at which the first packet of transmitter is released<sup>1,2</sup>. There is a fluctuating delay between pulse and response, its statistical distribution in one particular case being shown in Fig. 3. With brief pulses it was consistently found that the release

Fig. 1. End-plate potentials recorded with intracellular electrode from frog muscle paralysed with tetrodo-toxin. Temperature 7° C. Depolarizing pulses applied directly to nerve terminal. Pulse strength indicated in bottom trace of each column. Pulse duration 0.5 msec. Left column, weak current. The 3 top records consist of pairs of superimposed traces. There are 3 unit e.p.p.'s and 9 failures, in response to 12 pulses. Right column, stronger current. The 3 top records consist of 3 superimposed traces, showing one failure and 8 responses (note lower amplification).

Fig. 3 Latency distribution of end-plate potentials evoked by constant current pulses of 0.68 msec duration. Temperature  $4-6^{\circ}\text{C}$ . Ordinate: number of observed responses. Abscissa: time-interval between start of depolarizing pulse and start of e.p.p.

does not begin until well after the end of the pulse; the probability of release then rises rapidly to a peak and gradually declines again within a few msec. The time-course of the probability of release after a brief pulse suggests that the secretion of acetylcholine is the end-product of a sequence of reaction steps set off by the displacement of the membrane potential. Little is known as yet about the nature of the intermediate reactions except that calcium ions must be involved in at least one of them<sup>7</sup>.

### Uncoupling the Sodium Pump

It is now widely accepted that the extrusion of sodium from living cells is associated with the splitting of ATP at the inside surface of the cell membrane<sup>1-7</sup>. The mechanism responsible is inhibited by cardiac glycosides and it is affected in a complicated way by potassium ions. With membrane preparations from most cells, glycoside-sensitive ATPase activity can be demonstrated only when both sodium and potassium are present<sup>8</sup>, and in red cells and nerve there is evidence that the sodium ions must be inside and the potassium ions outside<sup>6,7</sup>. This fits in with the known coupling between sodium efflux and potassium influx in these tissues, and suggests that under normal conditions the transport mechanism catalyses an exchange of sodium ions for potassium ions across the membrane using energy from the hydrolysis of ATP at the internal surface.

Under certain abnormal conditions, the transport mechanism appears to behave in a different fashion. In the absence of external potassium, red cells still show quite a large glycoside-sensitive sodium efflux, and they also show an increased sodium influx, which is partly glycoside-sensitive<sup>9</sup>. It has been suggested that this behaviour comes about when the carrier mechanism shuttles sodium ions backwards and forwards across the

membrane<sup>8,10</sup>; there is evidence for a similar 'exchange diffusion' in muscle<sup>12-14</sup> and in nerve<sup>11</sup>.

The experiments reported here were designed to elucidate the factors affecting the efflux of sodium, and its coupling to the influx of potassium and the hydrolysis of ATP, in red cells. By the process of 'reversible haemolysis'<sup>15,16</sup> cells were prepared containing ATP, magnesium, radiosodium and other constituents in pre-determined quantities, and the efflux of sodium into test solutions was measured.

Unless ATP or ADP was present, no glycoside-sensitive efflux of sodium was observed. (The ability of ADP to maintain transport is not surprising as the cells contain adenylate kinase.)

When cells were prepared containing a high concentration of sodium and a high concentration of ATP, it was found that the glycoside-sensitive sodium efflux could be abolished completely by the removal of external potassium (Fig. 1, top). Under these conditions efflux of sodium by the carrier mechanism appears to be tightly coupled to influx of potassium.

Fig. 1. Loss of  $^{22}\text{Na}$  from red cells.  $\bigcirc$ , 10 mM-potassium in incubation medium;  $\bigcirc$ , potassium absent from incubation medium;  $\bullet$ ,  $10^{-4}$  g/ml. ouabain in incubation medium.

Partial uncoupling could be achieved either by lowering the internal sodium concentration or by incorporating enough inorganic phosphate inside the cells to give a low ATP/P<sub>i</sub> ratio (say 1/5). The 'partially uncoupled' cells showed a reduced sodium efflux in the absence of external potassium, but ouabain caused a further reduction. Fresh intact red cells loaded with sodium-24 behaved in a similar manner (Fig. 1, middle).

When cells were prepared with a low internal sodium concentration and with a low ATP/P<sub>i</sub> ratio, it was found that the efflux of sodium was slightly increased by the removal of external potassium (Fig. 1, bottom).

Whatever kind of cells were used, in a medium containing 10 mM potassium the external sodium concentration did not affect the sodium efflux except at high concentrations, when the efflux was somewhat reduced. This reduction is to be expected, because at high sodium concentrations competition by sodium ions for the potassium selective sites becomes appreciable. Quite a different effect of external sodium was observed, both in intact cells and in re-sealed cells, under conditions which allowed 'uncoupled' efflux of sodium into a potassium-free medium. Replacement of all but 5 mM of the sodium by choline reduced the glycoside-sensitive sodium efflux to zero. This effect is easily explained if the 'uncoupled' sodium efflux represents exchange diffusion of sodium across the membrane. Rather surprisingly, at external sodium concentrations near zero, a glycoside-sensitive efflux of sodium was again detectable. The significance of this is not yet understood, but in crab nerves under comparable conditions (O, K; O, Na) Baker<sup>17</sup> found that an ouabain-sensitive efflux of sodium was accompanied by a loss of amino-acids from the cell—in crab nerve dibasic amino-acids are the chief internal anions.

Although it is clear that a low internal sodium concentration and a low internal ATP/P<sub>i</sub> ratio both tend to uncouple the pump, it is not at all clear why they do. It is tempting to suggest that the low internal sodium acts by increasing the amount of energy required to expel sodium ions, and the low ATP/P<sub>i</sub> ratio acts by reducing the amount of energy available from the hydrolysis of ATP (compare the suggested role of ATP/ADP ratio in the squid axon<sup>18</sup>); but even if this is true it is difficult to think of a plausible mechanism. The resemblances between the observations reported here and recent findings in frog muscle<sup>12-14</sup> and squid nerve<sup>11</sup> suggest that, whatever the mechanism is, it is not peculiar to red cells.

When red cells are expelling sodium in exchange for potassium there is evidence that, whether the sodium movement is downhill<sup>8</sup>, on the level<sup>19</sup> or uphill<sup>20</sup>, approximately three sodium ions are expelled for each molecule of ATP split by the pump. In attempting to invent hypothetical mechanisms for the transport system, it is important to know whether the same stoichiometry holds for the 'uncoupled' flux. We have therefore compared glycoside-sensitive sodium efflux and glycoside-sensitive ATP hydrolysis in 'partially uncoupled' cells with and without external potassium. It turned out that, though ATP was required both for the 'uncoupled' efflux of sodium and for the coupled exchange of sodium for potassium, the rate of hydrolysis of ATP associated with the 'uncoupled' flux was very much less. It was, in fact, not significantly greater than zero (Table 1), but because of scatter in the results a small utilization of ATP cannot be ruled out. We have also found that both the 'uncoupled' and the 'coupled' efflux of sodium are inhibited by oligomycin. With 1 µg/ml., inhibition of both fluxes was about 48 per cent; with 10 µg/ml., the 'uncoupled' flux was reduced by 91 per cent, the 'coupled' flux by 74 per cent.

The fact that the 'uncoupled' efflux requires the presence of ATP, though it is associated with little or no hydrolysis, suggests that ATP is required for the formation

Table 1. EFFECT OF EXTERNAL POTASSIUM ON THE RELATION BETWEEN Na EFFLUX AND ATP HYDROLYSIS IN 'PARTIALLY UNCOUPLED' RED CELL GHOSTS

	0	136 ± 11	0.032 ± 0.013

\* The specific activity of the intracellular sodium was not the same in the two experiments.

of a sodium carrier which, in the absence of external potassium and under conditions that allow uncoupling, shuttles sodium ions backwards and forwards across the membrane without itself undergoing any irreversible change. If potassium is present externally, sodium is exchanged for potassium and this process presumably leads to breakdown of the carrier and utilization of ATP for its resynthesis. Two points remain difficult to explain. Exchange diffusion requires a high level of sodium externally<sup>19</sup>; even in the absence of external potassium, it occurs only when the internal sodium-level is low or the ATP/P<sub>i</sub> ratio is unfavourable energetically.

We thank the Medical Research Council and the Nuffield Foundation for grants for apparatus, and the Consejo Nacional de Investigaciones Científicas y Técnicas, Argentina, for a personal grant to one of us (P. J. G.).

## HAEMATOLOGY

### Relation between Gm(f) and the Structure of the γ-Globulin Molecule

THE serologically detectable genetically determined antigens Gm(a) and Gm(b) are restricted to the F<sub>0</sub> (fast) fragment of the A (Heavy) polypeptide chains of human gamma-globulin<sup>1</sup>. In contrast, Gm(b<sup>w</sup>) is present in the F<sub>ab</sub> (slow) fragment, and its serological activity seems to depend on the 'quaternary' structure of the intact gamma-globulin molecule<sup>2</sup>. Gm(f) activity also is localized to the F<sub>ab</sub> fragment of gamma-globulin<sup>3,4</sup>, and is also present in the 5S product obtained by pepsin digestion of the 7S gamma-globulin molecule<sup>4</sup> (Table 1); Gm(a) and Gm(b) activities are lost during pepsin digestion. Recent studies<sup>5</sup> indicate that Gm(f) and Gm(b<sup>w</sup>) are similar but not identical. We report here the results of experiments with anti-Gm(f) and isolated A and B chains of gamma-globulin.

Table 1. INHIBITORY ACTIVITY IN Gm(f) AND Gm(a) SYSTEMS

	Proteolytic fragments						Chains			
	7S	6S	5S	4S	3S	2S	A	B	A	B
2 normal Gm(a+f+)	+	+	0	+	0	+	+	0	0	0
1 normal Gm(a-f+)	0	+	0	+	0	+	0	0	0	0
1 normal Gm(a+f-)	+	0	0	0	0	+	+	0	0	0
2 myeloma Gm(a+f-)	+	0	0	0	0	+	+	0	0	0
3 myeloma Gm(a-f+)	0	+	0	+	0	0	0	0	0	0

A and B chains were prepared by the method of Porter<sup>4</sup> from the isolated gamma-globulins of three Caucasian normal subjects, from the gamma-paraprotein of six Caucasians with multiple myeloma, and from a pool of 20-30 African donors in a village in Gambia. (The latter preparation and the isolated A and B chains investigated in Bristol were kindly supplied by Dr. S. Cohen.) After isolation of the A and B chains, they were suspended in distilled water at concentrations of 10 and 5 mg/ml., respectively, then diluted five-fold with normal saline. To avoid precipitation the protein solution of the A chains was added to the saline and mixed rapidly. (No haemolysis due to hypotonicity or to low pH was noted in the subsequent serological tests.) The A and B chains in each instance were shown to be free of significant contamination by contralateral chain or by intact gamma-globulin as judged by agar diffusion studies with specific antisera to A and to B chains.

In additional experiments 16 gamma<sub>A</sub>, 8 gamma<sub>M</sub> and 8 gamma<sub>M</sub>-paraproteins and 16 Bence-Jones proteins, all free of significant contamination as shown by agar diffusion studies with polyvalent and monospecific antisera, were also tested for Gm(f) activity.

The serological tests utilized stock O R<sub>1</sub>R<sub>1</sub> cells and also O D - /D - - cells, stored in glycerol but reconstituted by dialysis. The cells were coated with anti-D (P.H.A.) which sensitizes for Gm(f) but not for Gm(b) (ref. 7). After washing, the sensitized cells gave strongly positive antiglobulin reactions with rabbit antisera. Anti-Gm(f) Mau, diluted 1:4 for use with the R<sub>1</sub>R<sub>1</sub> cells, and 1:20 with the D - - cells, was used to establish a Gm(f) agglutination system. For inhibition studies, suitable dilutions of A chains, B chains, or a mixture thereof, were mixed with the anti-Gm(f), left for 10 min at room temperature, and the sensitized cells then added. In the Bristol studies, the tests were performed on tiles, and the tests read macroscopically 10 min after addition of the cells. In the serological studies in San Francisco, the tests were read as outlined elsewhere<sup>9</sup> after 2 h incubation at room temperature in 10 × 75-mm test-tubes, and subsequent centrifugation for 30 sec in a serological centrifuge.

Neither A nor B chains isolated from three Caucasian Gm(a+f+) normal individuals inhibited these Gm(f) agglutination systems, whereas the A but not the B chains strongly inhibited standard Gm(a) agglutination systems. In the latter systems, inhibition by the A chains was greater than that of the intact γ-globulin, as also noted independently by Cohen<sup>8</sup> and Lawler *et al.*<sup>9</sup>. Similarly, neither A nor B chains of either Gm(a+f-) or Gm(a-f+) myeloma proteins inhibited the Gm(f) system, although the A chains of the Gm(a+) but not of the Gm(a-) paraproteins inhibited the Gm(a) agglutination systems. (Addition of B chains to the A chains did not affect the degree of inhibition of the Gm(a) test systems.)

When A and B chains derived from Caucasian Gm(f+) γ-globulin were mixed together in equimolar amounts (assuming a molecular weight of 27,000 for L chains and 54,000 for H chains), Gm(f) activity reappeared (Table 2); in contrast, an equimolar mixture of African A and B chains did not inhibit Gm(f). Further, a mixture of equimolar amounts of African Gm(f-) A and Caucasian Gm(f+) B chains did not inhibit, whereas a mixture of equimolar amounts of Caucasian A and African B chains produced partial inhibition of the Gm(f) system.

Table 2. EFFECT OF MIXTURES OF A AND B CHAINS ON Gm(f) AGGLUTINATION SYSTEM

Test system*	A chains B chains		Chain source Caucasian + African		African + Caucasian	
	Caucasian	African	Caucasian	African	Caucasian	African
(1) Man 1:4+ sensitized R <sub>1</sub> R <sub>1</sub> cells	0	+	+++	+++	+++	+++
(2) Man 1:20+ sensitized D - /D - - cells	0	+	+++	+++	+++	+++

0, Lack of agglutination = complete inhibition. +, ++, (+++), and ++++, Different degrees of agglutination.

\* Anti-Gm(f) Mau + sensitized cells + chains in saline tested for inhibition (lack of agglutination) in a solution of equimolar ratio and of total protein concentration of 8 mg/ml.

When unequal amounts of A and B chains from a Gm(f+) Caucasian donor were mixed together and assayed for Gm(f) activity, such activity decreased in direct relation to the degree of departure from equimolarity (Table 3), for example, a 1:2 mixture of A:B produced partial inhibition and a 1:3 mixture only very weak inhibition.

Table 3. EFFECT OF VARYING RATIOS OF A AND B CHAINS OF Gm(f+) GAMMA-GLOBULIN ON Gm(f) AGGLUTINATION SYSTEM

Anti-Gm(f) Mau	Molar ratio of A/B*						Saline control
	1:1	1:2	1:3	1:4	2:1	3:1	4:1
1:4 plus sensitized R <sub>1</sub> R <sub>1</sub> cells	0	+	++	+++	(+++)	+++	+++

\* Total protein of each solution is 8 mg/ml.

0, Lack of agglutination = complete inhibition.

The reported results are tentatively interpreted as supporting the hypothesis that Gm(f), like Gm(b<sup>w</sup>) (ref. 2), depends for its serological activity on the tertiary structure of the H chains; this in turn depends to a great extent on the configuration of the intact γ-globulin molecule. The connexion between Gm(f) and the A chains is further supported by recent results obtained with rabbit and primate antisera to A chain antigens<sup>10</sup> and with peptide mapping experiments of Gm(f+) and (f-) normal and myeloma proteins<sup>11</sup>. Further, Gm(f) activity was absent from 16 purified Bence-Jones proteins (at 4 mg/ml.); Bence-Jones proteins, as shown by Edelman and Gally<sup>12</sup>, are B chains devoid of A chain.

These results are of interest since the two currently defined allotypic loci in rabbits *Aa* and *Ab* define antigens present in the Heavy and Light chains respectively of rabbit gamma-globulin, and since the allotypic antigens *Aa* 1, 2 and 3 are localized to that part of the H chain which is within the F<sub>ab</sub> fragment<sup>13</sup>. Further, the six currently defined allotypic antigens *Aa* 1, 2, 3 and *Ab* 4, 5, 6 are all present in gamma<sub>M</sub> as well as gamma<sub>A</sub>-globulin<sup>14,15</sup>. Hence, it might be anticipated that Gm(f) would also be present in a portion of the A chain (presumably within the 'A piece') shared in common by the gamma<sub>A</sub>-, gamma<sub>M</sub>- and gamma<sub>M</sub>-globulins. However, in additional experiments, none of 8 gamma<sub>A</sub>- and none of 8 gamma<sub>M</sub>-paraproteins displayed Gm(f) activity at concentrations of 4 mg/ml., whereas 7/16 purified gamma<sub>A</sub>-paraproteins inhibited Gm(f) agglutination systems at concentrations as low as 0.25 mg/ml. In one Gm(f+) normal individual, the isolated gamma<sub>A</sub>-globulin was positive for Gm(f), but the isolated purified gamma<sub>A</sub>- and gamma<sub>M</sub>-globulins were not. Hence the Gm(f) antigenic determinant appears to be restricted to gamma<sub>A</sub>-globulin, and probably is localized to a portion of the gamma<sub>A</sub> A chain other than the A piece. Similar conclusions have been obtained from peptide-mapping studies<sup>16</sup>.

We thank Dr. D. Bergsmael for some of the Bence-Jones proteins used in these studies, Dr. G. H. Tovey for advice and help and Miss Hope Nerangis for assistance. This research was supported by U.S. Public Health Service

## PATHOLOGY

### Sensitization to *Khaya anthotheca*

AFRICAN mahogany is a timber which has been used extensively in the furniture trade since the early part of the century. It is derived exclusively from the *Khaya* genus and commercial supplies consist principally of *K. ivorensis* and *K. anthotheca* with smaller amounts of *K. grandifoliola*<sup>1</sup>. The timber is not usually regarded as troublesome as an irritant and, indeed, only a very few cases have been reported<sup>2</sup>. It was rather surprising, therefore, to have our attention directed to an outbreak of dermatitis in a factory in which large quantities of the timber were being processed, and it was decided to investigate this more fully.

Seven or eight cases among approximately 75 employees had occurred some two years previously, and the cases recorded here, involving a similar number, occurred in the three months prior to the start of this investigation. Men engaged on finishing operations (sanding, etc.) were mainly concerned, the face, forearms and back of the hands being affected, the eyelids swelling slightly or moderately. The back and sides of the neck were not involved. This pattern suggested a direct contact sensitization to a dust or volatile agent and not a photodermatitis. The eruptions usually subsided with varying (but usually brief) periods away from work and on return the affected men were moved to other jobs and remained clear.

To determine whether one or all three *Khaya* spp. were involved in this sensitization seven employees affected were patch tested to dust prepared from authentic samples of *K. ivorensis*, *K. anthotheca* and *K. grandifoliola* and four of these to wood dust from the factory. (It is not possible to distinguish between the woods comprising the commercial *Khaya* spp. by anatomical examination of the wood alone.) The tests were carried out by the standard method<sup>3</sup> and read at 48 and 96 h. Two other men who had developed a sensitivity to African mahogany (though not employees from the same factory), who were seen as routine patients by one of us (D.S.W.), were also tested. Apart from one 'false case', negative to all woods and extracts (see following), the remaining eight reacted strongly to authentic *K. anthotheca* (three giving a strongly intensified 96-h reaction), and in four cases confirmatory positives were obtained with the actual sawdust from the factory. No reactions were obtained with *K. ivorensis* or *K. grandifoliola*.

The sawdust of *K. anthotheca* was then Soxhlet-extracted successively with light petroleum, ether, acetone and

methanol, and the crude extracts were used to patch test six men. In addition patches were also applied of the fully extracted sawdust and of anthothecol (I) (ref. 4), a pure crystalline constituent which has been isolated from *K. anthotheca* but not from the other two species<sup>5</sup>. Five out of the six men reacted to the extracts, often with delayed reactions, there being little variation in the degree of reaction obtained with each extract, though one man reacted only to the petroleum extract. In five cases the completely extracted sawdust (10 per cent in petrolatum molle) gave no reaction; in the sixth case a quickly subsiding positive reaction occurred (probably a false positive). Finally, reactions, some severe, occurred with 1 per cent and 0.1 per cent anthothecol in acetone on all six men tested.

As controls *K. anthotheca* dust was added to a routine battery of patch tests in ten patients not sensitized by the wood, and in four cases anthothecol (0.1 per cent) patches were also added. No reactions occurred in either group of tests.

From these results it is clear that *K. anthotheca* contains sensitizing substances which can be removed by solvent extraction. The tests with anthothecol, a compound found mainly in the petrol extract, show that this is one of them. However, the equally sensitizing action of the subsequent ether, acetone and methanol extracts suggests that other active constituents may be present, though the presence of traces of anthothecol in each of these extracts cannot be excluded.

The results establish without doubt that *K. anthotheca* dust can cause sensitization and that this was the cause of the trouble in the cases investigated. It should be remembered, however, that African mahogany has been used for many years, apparently without trouble. One possible reason for the present outbreak may be that the consignment contained a particularly high proportion of *K. anthotheca*. Another possibility is that logs unusually rich in the sensitizing constituent(s) may have been included in the consignment. This phenomenon is encountered in teak in which a certain variety rich in deoxylapachol has enhanced irritant properties<sup>6</sup>. The results recorded here should be considered in the light of the amount of African mahogany used annually, which must contain a considerable proportion of *K. anthotheca*. The apparent almost trouble-free use of this timber for many years may indicate that the present outbreak is non-typical, and further evidence is necessary before *K. anthotheca* can be generally regarded as a troublesome irritant timber.

### Cathepsin A In Nutritional and Hereditary Muscular Dystrophy

DURING the past few years, several laboratories<sup>1-3</sup> have reported that the activities of many of the acid hydrolases of skeletal muscle are greatly increased in wasting diseases from different causes. Although the progressive loss of muscle mass in these conditions is generally attributed primarily to this enhanced activity of the acid hydrolases, there is little direct experimental evidence in support of this hypothesis. Furthermore, other enzymes involved in protein catabolism, such as alkaline protease<sup>4</sup> and peptidases<sup>5</sup>, have been shown to be elevated in dystrophic muscle. The normally low levels of these enzymes in skeletal muscle and the limited knowledge of their substrate specificities have hindered a better understanding of the mechanism of the wasting process.

From skeletal muscle of rabbits and chickens we have isolated a highly purified protease<sup>6</sup>, similar in its properties to cathepsin D of spleen<sup>11</sup>, which in liver has been shown to be localized in the lysosomes<sup>12</sup>. Unpublished data obtained with this purified enzyme freed of other known cathepsins show that it does hydrolyse certain muscle constituents but that, in itself, it cannot account for all the observed increase in dystrophic muscle autolysis.

This communication reports our finding that the activity of another proteolytic enzyme, cathepsin A, shown by Fruton and Bergmann to hydrolyse a number of peptides containing tyrosine or phenylalanine and glutamic acid<sup>13</sup>, is greatly increased in skeletal muscle of dystrophic animals.

Nutritional muscular dystrophy was produced in rabbits by feeding them a vitamin E-deficient diet<sup>14</sup>. Two types of control were used: animals maintained on the deficient diet but given oral supplements of DL- $\alpha$ -tocopherol, and animals maintained on stock diets. There were no demonstrable differences in enzyme-levels in either type of control. Chickens with hereditary dystrophy<sup>15</sup>, and some controls, were raised from eggs supplied by the Department of Genetics, University of Connecticut; other controls were purchased from commercial suppliers. There was likewise no difference in enzyme-levels in either type of control. All chickens were 3-4 months old when used for these experiments.

Cathepsin A levels in breast muscle of the chicken and in mixed thigh, leg and back muscles of the rabbit were measured in a 2 per cent potassium chloride homogenate (1:4 w/v) prepared in a Waring blender to which 'Triton X-100' had been added in a final concentration of 0.2 per cent. In experiments to be reported elsewhere, cathepsin A has been found to be associated with the lysosomes isolated from liver and to be fully released under these conditions. The release of tyrosine due to the enzymatic hydrolysis of carbobenzoxy- $\alpha$ -glutamyl-L-tyrosine (Mann Research Laboratories, Inc.) by cathepsin A was determined by the ninhydrin colorimetric procedure of Moore and Stein<sup>16</sup>. There was no detectable non-enzymatic release of tyrosine under the assay conditions used, nor did the substrate itself react with ninhydrin. The reaction mixture, containing 0.4 ml. homogenate, 0.2 ml. 0.2 M sodium acetate, pH 5.0, and 0.4 ml. 0.038 M substrate or H<sub>2</sub>O, was incubated at 37°-38° C for 2 h. The reaction was stopped by the addition of 1.0 ml. of 10 per cent trichloroacetic acid and the mixture was heated in a 50°-55° C bath for 10 min and centrifuged for 15 min at low speed. The supernatant was diluted 1:5 with water. Aliquots of 0.10-0.20 ml. of the diluted supernatant were used for the colorimetric ninhydrin determination, with the appropriate level of tyrosine as a standard. Protein was estimated by the procedure of Lowry *et al.*<sup>17</sup>. The results are shown in Table 1.

The data indicate that the activity of cathepsin A is significantly increased in both types of muscular dystrophy. It is noteworthy that the skeletal muscle of normal rabbits appears to be almost free of this protease,

Table 1. CATHEPSIN A ACTIVITY IN DYSTROPHIC MUSCLE  
amoles tyrosine liberated  
per mg protein

Rabbit	
Control (5)	0.012 [0-0.032]
Vitamin E-deficient (5)	0.197 [0.118-0.371]
Chicken	
Control (7)	0.125 [0.094-0.170]
Dystrophic (8)	0.292 [0.230-0.366]

The numbers in parentheses refer to the number of animals in that group and the square brackets enclose the range of values obtained.

whereas in the breast muscle of the chicken the level of this enzyme is comparatively high and approaches that seen in muscle of the vitamin E-deficient rabbit. The significance of these results in terms of the overall enzymatic hydrolysis of proteins in various species and in dystrophy cannot be evaluated until a more highly purified enzyme preparation, free of other cathepsins, has been obtained. Indeed, it is not yet known whether cathepsin A does actually have proteolytic activity or whether it is restricted in its action to the hydrolysis of small peptides. However, preliminary data obtained with a partially purified cathepsin A preparation indicate that haemoglobin, at least, is not a good substrate for this enzyme.

Our present investigations with isolated cathepsin A, as well as other proteases, are directed toward the elucidation of the role of these enzymes in protein catabolism and a better understanding of the wasting process.

### HISTOLOGY

#### Visualization of the Nuclei of the Basal Melanocytes of the Black Guinea-pig and of Human Skin under the Bright Field Microscope

THE nuclei of the melanocytes isolated from the black guinea-pig and from human skin by the method of Shukla, Karkun and Mukerji<sup>1</sup> are always masked by the dense melanin present in the cytoplasm (Figs. 1A and 2B). A method to demelanize the cells and visualize the nuclei is reported here.

A saline suspension of melanocytes isolated by the technique of Shukla *et al.* from the skin of the dorsal surface of the black region of the ear of the spotted guinea-pig, or the peroneal surface of the leg of normally pigmented human subjects, is mounted on albuminized slides and dried at 58° C in an oven. After an hour of drying the

Fig. 1. The isolated basal melanotic melanocyte prepared from the dorsal surface of skin of the ear of the guinea-pig. (A) The melanocyte after DOPA reaction where the internal structures are completely masked by the densely packed melanin and premelanin. (B) The large, basophilic, egg-shaped nucleus (n) in the centre of the partially demelanized melanocyte after Mayer's haemalum stain. Melanin granules (m) are visible in the dendritic processes. (C) The antero-posterior view of the egg-shaped nucleus (n) of the completely demelanized melanocyte with two characteristic notches in its boundary wall near the anterior end, marked s in the figure. Haematoxylin-eosin stain  $\times 600$ .

(B) Lateral view of the nucleus (n) in the completely demelanized cell after Mayer's haemalum stain. A notch at the anterior end is shown as s. (C) Shows the antero-posterior view of the nucleus of the melanocyte. One of the two characteristic notches at the anterior end is shown as s. Haematoxylin-eosin stain  $\times 600$ .

cells are affixed to the slides, and fixed in 5 per cent formal-saline for 30 min and washed in running water for 4 h. The slides are placed in 40 per cent peracetic acid freshly prepared by the method of Findley, Swern and Scanlan<sup>2</sup>. They are taken out after 12 h, washed in running water

for 1 h and stained by Harris's haematoxylin and eosin and Mayer's haemalum by the method of McManus and Mowry<sup>3</sup>. These are then dehydrated in ascending series of alcohol, cleared in xylol, mounted in balsam and examined under the microscope.

The nucleus of the basal melanotic melanocyte of the guinea-pig has been observed to be a constantly occurring basophilic structure in the centre of each cell (Fig. 1B). It is large in size, occupies nearly the whole of the cytoplasm of the cell and is concave in the long axis corresponding to the curvature of the parent melanocyte<sup>4</sup>. In the antero-posterior aspect, the nucleus has a smooth and regular border and is shaped like an elongated egg, the narrow end being directed towards the dendritic process which is stouter than the others (Fig. 1C). A little posterior to the narrow end there are two smooth indentations, one behind the other, on the boundary wall of the nucleus.

The nuclei of the basal melanotic melanocytes of the skin of human subjects also occur as constant basophilic structures. The concavity in the long axis of the nucleus of the melanocyte of human skin appears more pronounced and, therefore, is visualized often as a folded structure (Fig. 2B). Occasionally, the nucleus in the unfolded form is seen; it is egg-shaped, and indented like the nucleus of the guinea-pig melanocyte (Fig. 2C). It is smaller in size than the nucleus of the guinea-pig and there is a broad rim of cytoplasm around it.

Visualization of the nucleus of the melanotic melanocyte of the guinea-pig and human skin under the light microscope has led us to the study of the structure of the nucleus as related to the formation of melanin.

## BIOLOGY

### Manganese Dioxide as a Remedy for a Physiological Disease of Rice associated with Reduction of the Soil

A PHYSIOLOGICAL disorder of rice known as 'suffocation disease' occurs on the poorly drained soils of north-eastern Taiwan. The disease, which is characterized by a reddish-brown discoloration of the older leaves, stunted growth, root rot, and low yield, has been attributed to excessive reduction of the soil<sup>1,2</sup>. As the recommended remedy<sup>3</sup> of draining the fields to facilitate oxidation of the soil by atmospheric oxygen is not feasible during the rainy season, chemical retardation of reduction of the soil was investigated in a greenhouse experiment.

Of the five retardants of reduction examined (potassium chlorate, potassium perchlorate, sodium nitrate, manganese dioxide, and 4-chloro-3,5-xyleneol), manganese dioxide at 0.4 per cent by weight of the dry soil (the single level used) retarded soil reduction, corrected the physiological disorder in the problem soil from Taiwan (Fig. 1), and improved the growth of rice on three other problem soils (Table 1).

The benefits apparently were not a response to the micronutrient, manganese, or to impurities in the manganese dioxide because: (a) all soils had adequate concentrations of water-soluble manganese; (b) 25 p.p.m. of manganese as manganous chloride applied to the soils produced no response; (c) manganese dioxide prepared in the

Fig. 1. Tungahan silt loam with  $\text{MnO}_2$  (right), without  $\text{MnO}_2$  (left)Fig. 2. An acid sulphate soil with  $\text{MnO}_2$  (right), without  $\text{MnO}_2$  (left)

laboratory from chemically pure potassium permanganate gave a better response than commercial manganese dioxide. The higher redox potential and smaller concentrations of ferrous iron and organic reduction products in the soil solution of the manganese dioxide treatment than in the control (Table 2) suggest that the benefits were associated with retardation of soil reduction. Removal of carbon dioxide as the sparingly soluble manganese carbonate may have been an additional benefit<sup>4</sup>. The dramatic response to manganese dioxide in the acid-sulphate soil from Viet Nam (Fig. 2) may be ascribed to a slightly higher pH ( $\Delta\text{pH} = 0.2$ ), markedly lower concentrations of aluminium ( $\Delta\text{Al} = 30$  p.p.m.) and iron ( $\Delta\text{Fe} = 600$  p.p.m.) in the soil solution, and perhaps to

a more favourable iron:manganese ratio than in the control.

Manganese dioxide retarded the accumulation of harmful reduction products, corrected a physiological disease of rice on a problem soil and improved the growth of rice on three acid soils. Because manganese dioxide: (a) undergoes reversible oxidation-reduction when rice soils are alternately drained and flooded; (b) is not likely to suffer appreciable losses in poorly drained soils; (c) is a relatively inexpensive commercial commodity, its use as a remedy for physiological diseases caused by soil reduction and as an amendment for acid lowland rice soils merits attention.

### Carbon-14 Labelled Photosynthate in Wheat Root Exudates

There is abundant evidence that organic compounds are exuded from the roots of intact plants<sup>1</sup>, but the amounts are small, and to obtain sufficient material for identification even by paper chromatography it is necessary to collect exudates from a large number of plants or from one plant over a long period. To overcome these difficulties a sensitive method using radioactive labelling has been developed which enables short-term studies on the exudation by roots of individual wheat plants to be used.

Wheat seed (variety 'Gabo') was surface sterilized with calcium hypochlorite, germinated on agar plates and two seeds planted per test-tube (3.5 cm diam. × 20 cm) containing sterile Hoagland and Arnon medium<sup>2</sup> adjusted to pH 6.5 after autoclaving. The seeds were supported on glass fibre 2 mm mesh stretched over one end of a glass cylinder standing in the nutrient solution. After 5–6 days in the glasshouse, when the leaves and roots were 10–12 cm long, the solutions were checked for sterility. The plants were carefully removed from the tube together with the supporting mesh and cylinder. The mesh was cut away so that the roots were not handled, and in this way damage and contamination were avoided. The plants were then transferred to an apparatus made of 'Perspex' (Imperial Chemical Industries, Ltd.) designed to support them so that the tops could be exposed to  $^{14}\text{CO}_2$  and isolated from the roots which were immersed in sterile liquid. The apparatus was sterilized before use by soaking overnight in a solution of sodium hypochlorite. Air containing approximately 10  $\mu\text{c}$ . of  $^{14}\text{CO}_2$ , prepared from  $\text{Na}_2^{14}\text{CO}_3$  and lactic acid, was injected through a port into a tube enclosing the foliage. After 1 h in sunlight, when  $^{14}\text{CO}_2$  was almost completely assimilated, the tube was removed and the plants were allowed to photosynthesize in the normal atmosphere. The liquid around the roots (water or plant nutrient solution) was changed at intervals and aliquots were checked for sterility. Usually the solution remained sterile or showed insignificant contamination over 24-h collection periods.

In addition to exuded organic compounds the solution surrounding the roots would contain dissolved  $^{14}\text{CO}_2$ , derived from metabolism of root tissue. This was removed by adding  $\text{Na}_2\text{CO}_3$  as unlabelled carrier, acidifying the solution to pH 2–3 and bubbling air through it for 30 min. Other volatile compounds may have been removed by aeration. Approximately 80 per cent of the total counts of a solution which had not been aerated during collection of exudate were removed by this treatment. The solution was neutralized, 5 mg glucose added, then evaporated to

dryness in a silica boat in a vacuum oven at 55° C. The dry residue was combusted to carbon dioxide in a furnace and the carbon dioxide evolved collected in sodium hydroxide and precipitated as barium carbonate. The radioactivity of the barium carbonate was determined by liquid scintillation counting after suspending it in a thioxotrophic gel-toluene counting solution. The reproducibility of this method was checked using  $^{14}\text{C}$ -glucose, uniformly labelled. From the results of 5 replicates, the standard error, expressed as a percentage of the mean, was  $\pm 3.6$ .

Radioactivity first appeared in the exudate 4–5 h after the start of exposure of the tops to  $^{14}\text{CO}_2$  and continued for the final period of collection of 24–48 h. The radioactivity of the exudates collected over a 48-h period from roots in plant nutrient solution indicated that approximately 0.1 per cent of carbon-14 assimilated was exuded by the roots. The amount of exudate, as indicated by radioactivity, was increased when roots were immersed in distilled water rather than plant nutrient solution during the course of the experiment (Table 1). There are indications that exudation of  $^{14}\text{C}$ -labelled compounds from roots is affected by aeration of the roots—less radioactivity being exuded at low oxygen tensions. Several radioactive compounds were detected when paper chromatograms of the root exudates were examined by autoradiography.

Table 1. EXUDATION OF RADIOACTIVITY BY WHEAT ROOTS IN WATER AND PLANT NUTRIENT SOLUTION

Roots immersed in:

7248* (455)†	4570* (610)†

\* Counts per 100 sec in exudate from 2 plants over 15–5 h.

† S.E.

This investigation has shown that labelled photosynthate can be used to trace the exudation of organic compounds from intact roots. Application of carbon-14 to the plant as  $^{14}\text{CO}_2$  is considered superior to the application of labelled sugars or amino-acids to leaves or cut petioles, since the normal translocated materials of the plant become labelled and there is no danger of loading the plant with unrealistic concentrations of any particular compound, a factor which might alter exudation patterns.

The use of  $^{14}\text{CO}_2$ -treated plants for root exudate studies has been reported previously<sup>3,4</sup>, but the work recorded here has shown that the technique can be used for short-term studies for which complete asepsis is unnecessary, measuring the exudation from individual plants and even from different portions of the same root. By growing plants in the presence of  $^{14}\text{CO}_2$  for longer periods it may be possible to obtain equilibration of labelling in the plant and the radioactivity exuded should then yield quantitative data of exudate components.

### Method to study Germination of Fungus Spores in Soil

VARIOUS methods have been devised to study the germination of fungus spores in the soil<sup>1,2</sup>. These methods have the disadvantage that the spores are held under conditions different from those in natural soil. Boosalis<sup>3</sup> developed a method which eliminates the disadvantages of other methods but is rather cumbersome. The following method was found to be satisfactory for application in studies on soil-fungistasis and for determining the effect of various

soil amendments on the germination of conidia of *Helminthosporium sativum* P.K. and B. in the soil.

The soil is air-dried and sieved through a 1-mm mesh sieve to obtain a uniform maximum particle size. Both halves of a Petri dish are then filled with the soil and the surface of each levelled. To retain a smooth surface the soil is moistened by means of a spray gun operating at 5 lb./sq. in. Care must be taken not to blow holes in the soil surface by holding the spray gun too close to the soil. If an absolutely level surface is not required, the soil can be moistened by means of a pipette. The amount of water applied will be determined by the soil type and the nature of the test. The spores (in suspension) are applied by means of a pipette to the soil in the lid part of the Petri dish (Fig. 1). The number of spores must be sufficient to permit easy recovery after incubation. A disk of plastic or nylon mesh (approx. 2 mm), with a diameter similar to that of the Petri dish, is placed on the other half and pressed down firmly. The purpose of the mesh is to separate the soil surfaces and yet provide contact and air spaces. The Petri dish is then assembled as indicated in Fig. 1 and the two parts lightly pressed together to ensure contact between the soil surfaces. It is then incubated under conditions suitable for the germination of the spores.

Fig. 1. Diagrammatic representation of Petri-dish assembly for tests of spore germination in the soil

After incubation, the two parts of the Petri dish are separated carefully, and a spore print is made with an agar strip<sup>4</sup> which is examined microscopically. The agar strips can also be incubated in a moist chamber to determine the viability of ungerminated spores.

### Male and Female Influence of Adult Individuals on Undifferentiated Larvae of the Parasitic Nematode *Paramermis contorta*

PREVIOUS experimental infestations of *Chironomus tentans* larvae with the nematode *Paramermis contorta* confirmed that crowding plays a major part in determining the sex of the parasites<sup>1</sup>. Observations by Caullery and Comas<sup>2</sup> on natural populations showed that an increase of the degree of infestation results in an increase of the relative frequency of the males of *Paramermis*. It was also established that, at a given degree of infestation, the relative frequency of male *Paramermis* decreases with the increasing lengths of the *Chironomus* larvae at the moment when they are penetrated by the nematode<sup>3</sup>.

Work has now been carried out in order to establish whether, in cases of two successive infestations, the individuals which develop first in the haemocoel of the host can influence the sexual differentiation of the young individuals that penetrate successively the *Chironomus* larva.

About 4,000 larvae parasitized by a single nematode were obtained from about 10,000 larvae of *Chironomus*

Fig. 1

*lentans* which were subjected to a first light infestation with *Paramermis contorta*. The remaining *Chironomus* larvae, which were parasitized by more than one nematode or were not parasitized at all, have not been considered in the prosecution of the experiments. Nine days after the infestation, with the parasites reaching the medium length of 13 mm, a second massive infestation has been carried out on the *Chironomus* larvae parasitized by the single nematode.

A second lot of 10,000 *Chironomus* larvae of the same age as those which were previously parasitized was subjected in the same way as the first and single massive infestation of *Paramermis*.

Repeated controls demonstrated that the death rates of both the parasitized larvae and of the nematode remained at such low levels that they could not influence in the least the results of the experiments.

All the *Chironomus* larvae were fixed fifteen days after the last infestations and were afterwards opened in order to sex the parasites.

This allowed significant differences to be established in the sex ratios of the following three groups of parasites: (1) the parasites which penetrated the *Chironomus* larvae simultaneously in the course of a single infestation; (2) the nematodes which penetrated *Chironomus* larvae which already contained a single female *Paramermis*; (3) the nematodes which penetrated *Chironomus* larvae which already contained a single male *Paramermis*. It is easy to make out at this stage the parasite which has been introduced at the first course of infestation from those which have been introduced in the second course and are much smaller.

84.53 per cent male individuals (15.47 per cent female individuals) were obtained in the first group (Fig. 1A). This group is represented by 6,595 parasites which were obtained from 4,517 *Chironomus* larvae which had been subjected to the single massive infestation eleven days after their births.

94.56 per cent male individuals (5.34 per cent female individuals) were obtained in the second group (Fig. 1C). This group is represented by 1,581 nematodes which penetrated 1,082 *Chironomus* larvae which already contained a single female *Paramermis* from the first course of infestation.

61.80 per cent male individuals only (38.20 per cent females) were obtained in the third group (Fig. 1B). This group is represented by 6,860 nematodes which penetrated 2,837 *Chironomus* larvae which already contained a single male *Paramermis* from the first course of infestation.

In the first, second and third groups (which are all perfectly comparable) the sex ratios are significantly different. A close examination shows that the percentage of females is significantly lower in the group which penetrated the *Chironomus* larvae which were already parasitized

by a single female nematode (group 3) than it is in the group of parasites which penetrated the *Chironomus* larvae in a single course of infestation (group 1). The percentage of females is, on the other hand, significantly higher in the group which penetrated *Chironomus* larvae which were already parasitized by a single male nematode (group 2) than it is in group 1. The percentage of females of group 1 is thus intermediate between the percentages of groups 2 and 3.

Such results show that a female individual of *Paramermis* which develops first influences the sexually undifferentiated larvae of *Paramermis* which penetrate, at a later time, the *Chironomus* larva by favouring their differentiation in the male direction. A male individual of *Paramermis* which develops first influences on the contrary the undifferentiated larvae in the female direction.

The following influences are thus ascertained concerning sexual differentiation of *Paramermis contorta*: (1) the degree of infestation; (2) the length of the host; (3) the sex of the parasite which first penetrated the *Chironomus* larva.

It is already known through such classic examples as those of *Bonellia*, of *Orepidula* and of *Jones* that adult females may exert a male-determining influence on younger individuals. The female-determining influence by adult male individuals has now been demonstrated for the first time.

### A Method of Increased Sensitivity for detecting Single Antibody-forming Cells

THE plaque techniques of Jerne *et al.*<sup>1</sup> and of Ingraham and Bussard<sup>2</sup> for assaying single antibody-producing cells involve the lysis of erythrocytes suspended in three dimensions around the active cells in a supporting medium, agar or methyl cellulose. Maximum sensitivity with this system would be expected if a single layer of lymphoid cells and target erythrocytes was examined. A method has been devised which dispenses with supporting media and allows detection of cells producing antibody sufficient to lyse only 10-20 adjacent erythrocytes.

A sheet of paraffin wax 2 cm × 2 cm and 10μ thick is cut with a microtome, and a hole 1 cm diameter then punched in it with a cork borer. This sheet is dried on to a microscope slide forming a shallow 'chamber'. A suspension of the antibody-producing cells to be examined is made in Eagle's medium at 0° C, and complement and

Fig. 1. Cell from the efferent popliteal lymph duct of a sheep producing a small plaque by lysis of adjacent sheep red cells coated with bacterial polysaccharide

target erythrocytes added to final concentrations of 10 per cent each. The mixture is warmed to room temperature for a few seconds, and a small drop (about 5  $\mu$ l.) is pipetted on to the glass at an inner edge of the chamber. A round coverslip, 1.3 cm in diameter, is lowered slowly on to the drop, which spreads to fill the chamber and overflows it. Excess fluid is sucked off with a filter-paper around the edges of the coverslip, which settles on to the rim of paraffin beneath, and the chamber is sealed with heated paraffin-'Vaseline'.

Plaques begin to appear in the monolayer within 1-2 min when the slide is incubated at 37° C, and a maximum number may be counted after 20 min. Most plaques do not increase in size after 1-2 h. The number of nucleated cells in a chamber of measured size is determined directly by counting several (calibrated) high-power fields under the microscope. Slides may be handled quite roughly without disturbing the monolayers.

Table 1. COMPARISON OF THE SENSITIVITY OF THE 'AGAR PLATE' AND 'FREE SUSPENSION' TECHNIQUES FOR DETECTING SINGLE PLAQUE-FORMING CELLS

Origin of cells	Hours after primary antigenic stimulus	Antigen	Calculated Plaque-formers per 10 <sup>4</sup> nucleated cells			
			'Agar plate'		'Free suspension'	
			A*	B*	A*	B*
OBA mouse spleen	96	10 <sup>6</sup> sheep rbc	1,090	1,080	2,980	2,760
OBA mouse spleen	144	10 <sup>6</sup> sheep rbc	87	40	144	134
OBA mouse lymph node	120	10 <sup>6</sup> sheep rbc	232	215	875	950
Sheep: efferent lymph duct from popliteal node	88	10 <sup>6</sup> boiled <i>Salmonella muenchen</i>	<10	<10	11,200	10,500

\* Plaques were counted by me (A) and by an independent observer (B).

The main advantages of this modified technique are:

(a) Increased sensitivity: about three times as many haemolysin producers are counted with the 'free suspension' method as are seen with the 'agar plate' technique. Using sheep red cells coated with *Salmonella* lipopolysaccharide<sup>4</sup> as the target, sheep lymph node cells secreting antibody to the bacterium were found to produce large numbers of very small (30-40 $\mu$  diameter) plaques which could not be detected by the agar plate technique<sup>4</sup> (Fig. 1). Such very small spheres of lysis in agar are probably obscured by intact red cells above or below.

(b) All cells in a chamber are unobscured, and may be examined at high magnification.

(c) The free-suspension technique detects the characteristic localized agglutination of lipopolysaccharide-coated erythrocytes around sheep lymph node cells producing antibacterial antibody in a secondary response<sup>4</sup>.

The main disadvantage of the method is that not more than about 300,000 lymphoid cells may be incubated in

one chamber. Increasing the size of a single chamber is unsatisfactory.

## Unique Occurrence of Complemental Males in a Sessile Barnacle

ALTHOUGH most thoracic barnacles are hermaphrodite, males and females are known in some of the pedunculate species. Darwin<sup>1</sup>, who was the first to observe males, found them associated with both hermaphrodites and females in the two related genera, *Ibla* and *Scalpellum*. The females, except for lacking male organs, were similar to the hermaphrodites of related species. The males, however, were always very small and one or more were attached, either just inside the operculum or in pits on the inside of the scutum. As the association of males with hermaphrodites was unknown in the animal kingdom, Darwin<sup>1</sup> made a very careful study of the attached organisms and, by finding the characteristic scalpelliform antennae, male organs and spermatozoa, proved conclusively that they were the males of their respective species. The males attached to the hermaphrodites he called complemental males.

Darwin<sup>1</sup>, who had only six species of *Scalpellum* available for study, distinguished two types of males, both associated with either females or hermaphrodites. One type was similar in basic structure to the latter forms. This type was also found in the two species of *Ibla*. The second bore no resemblance to the female or hermaphrodite or, for that matter, to any pedunculate barnacle. These males lacked a mouth and prehensile cirri and were, when mature, mere sacs of spermatozoa. By 1908, one hundred and seventy species of *Scalpellum* had been described and intermediate types of males had been found. At this time, Pilsbry<sup>2</sup> divided the genus into four genera and, using the characters of the male as well as those of the hermaphrodite and female, he constructed a more or less natural key to the scalpelliform barnacles.

Since the monographs of Darwin<sup>1,2</sup>, many new species of both pedunculate and sessile barnacles have been described and many of the previously known species have been more fully studied, but males have never been found in any barnacles except in *Ibla* and *Scalpellum* (*sensu lato*). Consequently, we were astonished to find complemental males in a member of the sessile barnacles. In preparing a description of a new species of *Balanus*, it was noticed that frequently the rostrum, which is strongly concave internally, had a deep depression in the vicinity of the sheath. From these depressions, cyprids and males in various stages of development were recovered. Each of the barnacles to which a male was attached has an extremely long penis and, therefore, must be classed as hermaphroditic. The male is degenerate; it lacks a mouth but has vestigial cirri and typical antennules. Testes and seminal vesicles, as well as spermatozoa, are present in mature males.

This species primarily agrees with *Solidobalanus*, a sub-genus of *Balanus*, which is one of the most highly evolved of the sessile barnacles. A full description of the new species is in preparation. However, since the occurrence of complemental males in a sessile barnacle is so noteworthy, it seemed worthwhile to call this phenomenon to the attention of other cirripedologists. This work was

supported by grant GB-1684 from the National Science Foundation.

## MICROBIOLOGY

### Attachment of Marine- and Fresh-water Bacteria to Solid Surfaces

DURING an investigation of the factors influencing choice of substrates by the marine amphipod *Corophium volutator* (Pallas), I observed that distilled water induced many bacteria to detach from the surfaces of particles of marine sand<sup>1</sup>. A search of the literature revealed that this phenomenon had not been reported, and that there was little information on why aquatic bacteria attach to surfaces<sup>2,3</sup>.

It was therefore decided to examine the attachment of aquatic bacteria to surfaces under experimental conditions. The experiments were conducted as follows. Marine bacteria were grown in a sea-water nutrient broth consisting of meat extract 10 g, peptone 10 g, aged sea-water 1 l.; the broth used for fresh-water bacteria was made up of beef extract 1 g, yeast extract 1 g, peptone 1 g, de-ionized water 1 l. Cultures were always used during the log phase of growth. The mixed cultures were obtained by inoculating sea-water or fresh-water into broth. Clean glass microscope slides were suspended for 3 h in a particular culture. During this time many bacteria attached. The slides were then removed one at a time and placed into different test solutions. After 1.5 h the slides were removed. When they were examined, it was found that varying numbers of bacteria had detached, depending on the nature of the test solution.

In view of my observation on the effect of distilled water on marine bacteria attached to sand grains, it was of interest to determine the influence of reduced salinity on attachment. Mixed cultures of marine and fresh-water bacteria were therefore tested as described here. Experiments were run in triplicate. The test solutions used were 100, 25, 5 and 0 per cent sea-water; these dilutions were obtained by diluting sea-water with de-ionized water.

The results of these experiments (Fig. 1) show that marine bacteria remain attached only in high salinities, whereas the peak of attachment for fresh-water bacteria occurs in 5 per cent sea-water. These results have been substantiated by others on pure strains of marine and fresh-water bacteria, including the fish pathogen *Vibrio anguillarum* NCMB 829.

Further experiments with marine bacteria have shown that sea-water can be replaced by solutions of sodium chloride of the same ionic strength as sea-water. If, however, a solution of glycerol of the same osmotic strength as sea-water is used, many marine bacteria detach. This is not true of fresh-water bacteria.

It seems, then, that marine- and fresh-water bacteria require different ionic environments before they will remain attached to surfaces.

These results have implications for a number of fields of investigation. In rivers and estuaries, marine bacteria will only remain attached to solid structures when tidal flow produces water of high salinity; this would limit them to the mouth of estuaries. Similarly, fresh-water bacteria will only remain attached up-river, where salinity is low. These are important ecological considerations; it has, for example, been suggested that organic substances adsorbed on surfaces are there in higher concentration

Fig. 1. Influence of salinity on the number of marine and fresh-water bacteria which remain attached to glass slides. ●, Marine bacteria; ○ fresh-water bacteria. The ordinate represents the percentage of those attached to the 5 per cent sea-water slide (fresh-water bacteria), or the percentage of those attached to the 100 per cent sea-water slide (marine bacteria). The abscissa represents the salinity of the test solution expressed as a percentage of undiluted sea-water. Each point is the mean of three values.

than in the body of the water mass, and hence are more readily available to bacteria as a food source<sup>4-6</sup>.

The results described here are also of interest in relation to the development of fouling communities. It seems probable that bacteria are among the first organisms to attach to newly immersed surfaces in the sea<sup>7,8</sup>. Fig. 1 shows that they do not remain attached in low salinities. Under these conditions, any film which developed would consist of fresh-water micro-organisms. Now it is known that the larvae of sedentary marine invertebrates, when they explore surfaces as a prelude to settlement, are sensitive to the numbers and types of attached micro-organisms<sup>9</sup>. A change in these numbers and types, caused by low salinity water, would almost certainly be detected by such larvae, and would in all probability induce them to settle elsewhere. This, and larval mortality in low salinities<sup>10</sup>, are factors which may play a part in limiting the spread of marine fouling communities into fresh-water.

It is difficult to suggest reasons for the observations reported here, for not a great deal of information is available on the way aquatic bacteria attach to surfaces, or on any differences in the physical chemistry of the cell surface between marine- and fresh-water forms; however, a report of a correlation between membrane stability and salt tolerance in Gram-negative bacteria is of interest<sup>11</sup>. Certainly mortality does not appear to be a limiting factor<sup>12</sup>. These and related problems are at present under investigation.

I thank Vera Collins and Dr. G. D. Floodgate for helpful discussion and the Royal Society for a grant for apparatus.

# 'Lincomycin' Treatment of Staphylococcal Infection at High Altitude

EXPERIMENTAL data previously reported<sup>1,2</sup> indicate that exposure to simulated altitudes of 18,000 or 35,000 ft. reduces the resistance of mice to infection caused by respiratory challenge with airborne *Klebsiella pneumoniae*. This effect was most marked in mice kept at 35,000 ft. for 1 or 14 days.

In the present studies the resistance of mice to *Staphylococcus aureus* and the efficiency of antibiotic treatment at 35,000 ft. were determined.

The gaseous environment used consisted of 85 per cent oxygen and 10 per cent carbon dioxide. At reduced pressure, 179.3 mm Hg, this environment corresponds to sea-level-equivalent partial pressure of oxygen ( $pO_2 = 152$ ) and elevated partial pressure of carbon dioxide ( $pCO_2 = 17.3$ ). The temperature in the chamber was maintained at  $22^\circ \pm 1^\circ C$  at relative humidity 50 per cent.

Table 1. MORTALITY OF MICE INFECTED WITH *S. aureus*

Duration of exposure (days)	1 x LD <sub>50</sub>		8 x LD <sub>50</sub>		100 x LD <sub>50</sub>	
	Ambient	Altitude	Ambient	Altitude	Ambient	Altitude
3	5/10*	7/10	7/10	9/10	9/10	10/10
7	4/10	4/10	6/10	8/10	9/10	9/10
14	5/10	4/10	8/10	4/10	9/10	9/10
30	5/10	4/10	7/10	7/10	10/10	10/10
Mean %	47.5	47.5	70.0	67.5	92.5	95.0

\* Dead/total.

Swiss albino mice were kept in this environment continuously for up to 30 days. At various times they were challenged intraperitoneally with virulent *S. aureus*, strain 284 (UG-76). The dose concentrations of *S. aureus* were 1, 8 and 100 LD<sub>50</sub> per injection. The data summarized in Table 1 show that no differences were observed between the mortality of mice kept at 35,000 ft. and that of control mice kept at ambient environment.

To study the efficiency of antibiotic treatment, Swiss albino mice exposed to 35,000-ft. altitude for 3, 7, 14 and 30 days were infected intraperitoneally with 100 LD<sub>50</sub> units of *S. aureus* 284. 'Lincomycin' (the Upjohn Company) was selected as the antibiotic and was injected subcutaneously at three dose-levels: 0.5 OD<sub>50</sub>, OD<sub>50</sub> (median protective dose), and 3 OD<sub>50</sub>. The 'Lincomycin' treatment was initiated within 30 sec after inoculation with *S. aureus* and was repeated on three consecutive days for a total of four injections.

Table 2. EFFECT OF 35,000-FT. ALTITUDE ON 'LINCOMYCIN' TREATMENT OF STAPHYLOCOCCAL INFECTION

Duration of exposure (days)	<i>S. aureus</i> Control		0.5 OD <sub>50</sub>		OD <sub>50</sub>		3.0 OD <sub>50</sub>	
	Ambient	Altitude	Ambient	Altitude	Ambient	Altitude	Ambient	Altitude
3	90*	100	80	70	10	50	10	10
7	90	90	20	60	20	40	20	10
14	90	90	41	59	28	34	6	16
30	100	100	30	30	10	30	10	15
Mean %	92.5	95.0	25.2	54.8	17.0	38.5	11.5	12.6

\* Percentage mortality.

Table 2 summarizes the results. Treatment with 'Lincomycin' at 0.5 OD<sub>50</sub> or 1 OD<sub>50</sub> level was less effective in reducing the mortality of the altitude-stressed mice than of the control mice. At the 3 OD<sub>50</sub> concentration of 'Lincomycin' this difference was absent. The duration of exposure of the mice to the elevated altitude also affected the therapeutic value of the antibiotic. Increased mortality was observed in mice kept at altitude for 3 and 7 days. At 14 days the mortality was still higher than in the controls. At 30 days the mortality was almost the same in both experimental groups.

For statistical analysis ('t' test) the data from ambient and altitude experiments were pooled irrespective of the level of antibiotic or the duration of exposure. The differences in mortality between the two groups were significant at  $P < 5$  per cent.

From these exploratory experiments it appears that the efficiency of 'Lincomycin' therapy of staphylococcal infection is reduced when the host is kept at an altitude of 35,000 ft. for up to 14 days.

We thank Dr. J. Grady, the Upjohn Company, for the samples of 'Lincomycin' used in this work.

## GENETICS

### Paucity of Albumin Variants In Man

PLASMA albumin in mammals is a protein of molecular weight about 69,000 and consists of a single kind of polypeptide chain<sup>1</sup>. Until recently, the only genetic variants of this protein recognized in any mammal have been the very rare cases of 'bis-albuminaemia' in man<sup>2,3</sup>. However, it has recently been reported<sup>4,5</sup> that some breeds of horses and zebu cattle are polymorphic (as defined by Ford<sup>6</sup>) for electrophoretically different albumins, and these findings have prompted me to enlarge and record some data indicating that certain human populations are not similarly polymorphic. This conclusion is to be anticipated from the fact that filter-paper electrophoresis of human plasma has been carried out routinely in clinical laboratories all over the world for more than a decade with only a few cases of bis-albuminaemia being reported, even though this condition gives a conspicuously abnormal electrophoretic pattern with two well-resolved components. In this context one may note that starch-gel, which has now widely replaced filter-paper as supporting medium, is not more sensitive than filter-paper for the study of albumin in undiluted plasma, because the large quantity of albumin present distorts the electric field in the gel, leading to reduced resolution. However, as noted also by Ashton<sup>7</sup>, multiple albumins can be very sharply resolved in starch gels if the plasma is diluted, and the present survey is based on this technique.

Plasma or serum specimens, diluted 10-fold with distilled water, were examined by one-dimensional starch gel electrophoresis in discontinuous buffer systems at pH 8.6 and pH 5.1<sup>8,9</sup>. Each gel contained, as a control, a sample of 10-fold diluted serum from a known case of bis-albuminaemia, in which the mobility difference between the usual (faster) and unusual (slower) components is probably due to two charge units<sup>8</sup>. The separations obtained were such that a difference as great as or greater than one-quarter the magnitude in the control would have been recognized with certainty.

Seven hundred and forty-eight specimens were examined, without a single variant being recognized. The specimens came from the following populations: Glasgow hospital patients, 548; South Indian leprosy patients, 50; East African Karamojo, 50; West African Yoruba, 50; New Guinea Highlanders, 50. Of the Glasgow sample, 202 were collected in 1961 and were analysed at pH 8.6 only; the remainder were collected and analysed in 1965. The South Indian sera were collected in 1964, and the other foreign samples were collected earlier. All the sera had been stored frozen, the oldest of them for about six years.

These results show that the observed frequency of unusual alleles determining net charge differences in human plasma albumin is less than 0.001 in a Glasgow population, and less than 0.02 in some other populations. In another random survey an allele frequency of about 0.0005 was obtained in a largely Norwegian population<sup>3</sup>. Consideration of the work of routine clinical laboratories and of other research workers suggests that these values are much higher than the real values. It thus appears that man is not polymorphic (*sensu strictu*) for alleles detectable via electrophoresis at the structural locus for albumin.

The simplest and most important of the mechanisms leading to polymorphism is heterozygous advantage and, for any locus controlling an enzyme or other protein, heterozygous advantage will usually result from increased activity or altered specificity of the protein. Such a change can be a property of only few of the possible mutations at a locus (since most will result in decrease or loss of function) and may not be possible at all loci; thus one is led to expect that many protein structural loci will not be polymorphic.

That serum albumin is one of the proteins unlikely to be polymorphic in man receives some support from the existence of an albuminaemic individuals who show no serious impairment of health due to their almost complete lack of albumin<sup>2</sup>. This suggests that albumin function(s), far from being limiting to fitness, may in certain circumstances be almost dispensable.

I thank Dr. H. E. Hutchinson for providing the Glasgow sera; Dr. A. E. Mourant, Miss S. Povey and Mr. L. J. Horton for the Indian sera; Dr. J. P. Garlick for the African and New Guinean sera, and Prof. H. Harris for the bis-albuminaemic serum.

### Chromosomes of the Striped Indian Squirrel (*Funambulus pennanti*)

*Funambulus pennanti*, the striped Indian squirrel, is a small arboreal rodent characterized by three white stripes on its dorsal surface and two on the sides and is the predominant species of Northern India. So far as we are aware, the chromosome number of this species has not been reported. In fact, no information is available on chromosome numbers of any member of the genus *Funambulus*, family Sciuridae<sup>1</sup>. The results of an investigation into chromosome number and karyotype of this species are summarized in this report.

Bone marrow was processed for chromosome preparations by the method of Ford and Hamerton<sup>2</sup>. Each squirrel was injected with 0.5 ml. 0.025 per cent colchicine solution and killed 1 h later. Marrow from femurs was removed into hypotonic solution of 0.95 per cent sodium citrate in water warmed at 37° C. After 15 min in hypotonic solution at 37° C the cells were settled out by centrifugation at low gravity and fixed for 15 min in a freshly prepared chilled (1 : 3) mixture of glacial acetic acid and methyl alcohol. Air-dried preparations were made by the method of Rothfels and Siminovich<sup>3</sup> and stained with 2 per cent aceto-orcein. The slides were made permanent by passing them through two changes of n-butyl alcohol, and mounted in neutral canada balsam. All drawings, measurements and photographs were made from permanent slides. Only undamaged and well-spread cells with uniform contraction were selected for recording data. For chromatin length measurements, five cells were drawn with the help of camera lucida. The chromatin length figures given in the text are an average of five mitotic metaphase cells. The chromosomes were matched into pairs using relative length and arm ratio as criteria.

All but one of the 50 cells examined critically from two male squirrels available for study had 54 chromosomes in mitotic cells (Fig. 1). The only cell with a number devi-

Fig. 1. Typical metaphase plate and karyotype of *Funambulus pennanti* showing 54 somatic chromosomes.

ating from the normal had 52 chromosomes. Fig. 1 (below) shows the 54 chromosomes matched into 27 pairs and arranged in descending order of length, the pair of sex chromosomes being placed at the end. The longest chromosome in the complement was 6.67  $\mu$  in length and the smallest measurable one, chromosome 24, measured 1.46  $\mu$ . Chromosomes 25 and 26 are too small to be drawn accurately for length measurements. The 26 autosomes can be grouped into the following categories:

(A) Large chromosomes, ranging in length from 6.67  $\mu$  to 3.96  $\mu$ , include: (i) Subterminals: Chromosome numbers 1, 2, 6, 8, 11 and 13. Chromosome 11 has a satellite on the short arm. (ii) Telocentrics: Chromosome numbers 3, 4, 5, 7, 9, 10 and 12.

(B) Medium long chromosomes, ranging in length from 3.75  $\mu$  to 2.08  $\mu$ , include: (i) Subterminals: Chromosome numbers 17 and 19. (ii) Telocentrics: Chromosome numbers 14, 15, 16, 18, 20 and 21.

(C) Small chromosomes, ranging in length from 1.66  $\mu$  to 1.46  $\mu$  and less, include: (i) Metacentric: Chromosome 23. (ii) Telocentrics: Chromosome numbers 22, 24, 25 and 26.

Since the two animals examined were both males, it is difficult to say with certainty which of the sex chromosomes is the X-chromosome. It is more likely, however, that the longer one measuring 3.33  $\mu$  is the 'X' chromosome. The 'Y' then is a very short acrocentric chromosome indistinguishable from chromosomes 25 and 26.

*Note added in proof.* Since this report has been in the press, Rao and Sharda (*Cytogenetics*, 3, 342) have also reported the diploid chromosome number of *Funambulus pennanti* to be 54.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Sunday, September 5—Wednesday, September 8

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at Cambridge)  
—Continuation of 127th Annual Meeting.

Sunday, September 5

At 11 a.m.—Official Service in Great St. Mary's Church. Preacher, Prof. D. Nineham, Regius Professor of Divinity in the University of Cambridge.

Monday, September 6

At 10 a.m. and 2.30 p.m.—Symposium on "World Fuel and Power Resources and Needs".

At 8.30 p.m.—Prof. F. Hovie, F.R.S.: "Recent Work in the Field of Cosmology and Astronomy" (Evening Discourse).

Tuesday, September 7

At 10 a.m.—Prof. D. G. MacRae: "The Sociology of Secular Religions" (Presidential Address, Section N).

At 10 a.m.—Dr. G. F. Loodale: "Hugliens—a New Look with the Electron Microscope" (Darwin Lecture).

At 10 a.m.—Dr. M. Prutton: "Thin Films and Their Role in Computers" (Kelvin Lecture).

Wednesday, September 8

At 2.30 p.m.—Prof. H. J. Eysenck: "The Measurement of Intelligence" (Young People's Lecture).

Tuesday, September 7

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Address by Mr. John Macgregor, President of The American Society of Automotive Engineers.

Monday, September 13—Friday, September 17

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2)  
—International Conference on "The Microwave Behaviour of Ferrimagnetics and Plasmas".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HISTORICION THEORISTIAN (graduate member of the I.E.R.M. or with equivalent qualifications, and some years experience)—The House Governor (A), Charing Cross Hospital, London, W.C.2 (September 8).

PRINCIPAL BIOCHEMIST (with a good honours degree in chemistry or biochemistry and/or Ph.D. or other higher qualification) in the DEPARTMENT OF CHEMICAL PATHOLOGY at Ashton Street, Pembroke Place, Liverpool, 3.—The Secretary, The United Liverpool Hospitals, 80 Rodney Street, Liverpool 1 (September 8).

CLINICAL PSYCHOLOGIST (with an honours degree and preferably some postgraduate experience) to give assistance to the Principal Psychologist.—The Secretary to the Board of Governors, The National Hospital for Nervous Diseases, Queen Square, London, W.C.1 (September 10).

TEMPORARY ASSISTANT LECTURER or LECTURER in ORGANIC CHEMISTRY.—The Registrar, University College of Swansea, Singleton Park, Swansea (September 11).

LECTURER (Grade II) in MATHEMATICS (Pure or Applied)—The Registrar, University Senate House, The University, Bristol, 2 (September 13).

RESEARCH ASSISTANT (with qualifications in economic geography) in the GEOGRAPHICAL RESEARCH DIVISION—Prof. R. J. Harrison-Church, London School of Economics and Political Science, Houghton Street, London, W.C.2 (September 13).

ASSISTANT LECTURER in ZOOLOGY.—The Registrar, The University, Manchester, 13, quoting Ref. 165/65 (September 15).

ASSISTANT LECTURER (preferably with special interests in the scientific aspects of geography, for example, biogeography or climatology) in GEOGRAPHY.—The Registrar, The University, Manchester, 13, quoting Ref. 157/65 (September 15).

MARINE BIOLOGIST (with a good honours degree and research experience in marine biology) in the MARINE SCIENCE LABORATORIES to conduct fundamental research on sedimentary animals or algae and to supervise the work of a technician responsible for routine tests.—The Registrar, University College of North Wales, Bangor, North Wales (September 15).

RESEARCH ASSISTANT (with a degree or equivalent qualification in physics or applied science, and preferably experience in practical electronics) in COSMIC RAY PHYSICS to join a small group working on a research project deep in the gold mines of Southern India.—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (September 15).

LECTURER (with a distinguished academic record) in PHILOSOPHY in the DEPARTMENT OF GENERAL STUDIES, University of New South Wales, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 17).

MUSEUM ASSISTANT (with appropriate qualifications and experience) at the OXFORD AND BEXLEY MUSEUM.—The Borough Librarian and Curator, Civic Centre, Chelmsford, Essex (September 18).

CURATOR (qualified and experienced in archaeology and museum administration) of the ROYAL MUSEUM and other museums controlled by the City Council.—Town Clerk, Municipal Buildings, Canterbury, Kent (September 20).

LECTURER (with a special interest in physical chemistry) in the CHEMISTRY DEPARTMENT.—The Secretary, Royal Free Hospital School of Medicine (University of London), Hunter Street, London, W.C.1 (September 20).

LECTURER, Grade II (with special interests in electron microscopy and fine structure); and a LECTURER, Grade II (with special interests in veterinary biochemistry) in the DEPARTMENT OF BIOCHEMISTRY.—The Registrar, University Senate House, Tyndall Avenue, Bristol, 2 (September 21).

READER (with high academic qualifications, teaching experience and extensive research experience in mechanical engineering, and preferably some administrative experience) in MECHANICAL ENGINEERING (September 24); and a LECTURER (with good qualifications in mathematics and experience in teaching it in the secondary school) in EDUCATION (October 1) at the University of Queensland, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

JUNIOR RESEARCH FELLOW (graduate, preferably with specialized training or a special qualification in sociology or anthropology) in SOCIOLOGY in the Institute of African Studies, University of Ibadan, Nigeria.—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 28).

CHAIR OF EXPERIMENTAL PHARMACOLOGY.—The Registrar, University of Strathclyde, Glasgow, G.1 (September 30).

CHAIR OF PHARMACOLOGICAL TECHNOLOGY.—The Registrar, University of Strathclyde, Glasgow, G.1 (September 30).

CHAIR OF PSYCHOLOGY at Queen's College, Dundee.—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (September 30).

COURTESY TUTOR (with several years experience as Senior or Head Technician in a University or College of Technology Department of Biology, Botany or Zoology) for SCIENCE TECHNOLOGISTS in the FACULTY of SCIENCE, The University College, Dar es Salaam, University of East Africa.—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 30).

LECTURER/ASSISTANT LECTURER in the DEPARTMENT of GEOGRAPHY, University of Malaya.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, September 30).

POSTGRADUATE SCHOLAR (graduate with capacity for research who wish to proceed to the degree of Ph.D. in the fields of organic chemistry or physical and theoretical chemistry) in CHEMISTRY in the RESEARCH SCHOOL of CHEMISTRY, Australian National University.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, September 30).

RESEARCH ASSISTANT (with a degree in zoology or in forestry; previous experience in research, preferably involving field studies, would be an advantage) to work with the Lecturer in Forest Zoology on investigations into the ecology and biological control of forest insects.—The Secretary, The University, Aberdeen (September 30).

SENIOR LECTURER and LECTURER in CHEMISTRY; a SENIOR LECTURER in MATHEMATICS, and a SENIOR LECTURER and LECTURER in PHYSICS at Njala University College, Sierra Leone.—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 30).

ASSOCIATE PROFESSOR in the DEPARTMENT of GEOLOGY and GEOPHYSICS, University of Sydney, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 1).

RESEARCH ASSISTANT (with a degree in a biological subject) in the DEPARTMENT of BIOMECHANICS and SURGICAL MATERIALS at the Country Section, Royal National Orthopaedic Hospital, Stanmore, Middlesex, for work concerned with a study of the biological and mechanical properties of bone and orthopaedic implants.—The Dean, Institute of Orthopaedics, Royal National Orthopaedic Hospital, 224 Great Portland Street, London, W.1 (October 10).

RESEARCH STUDENT (with an honours degree or equivalent in metallurgy or physics) in the DEPARTMENT of PHYSICAL METALLURGY for the study of the reinforcement of metals by alumina fibres.—The Secretary to the Department of Physical Metallurgy (Ref. O.J.B.), The University, Birmingham, 15 (October 11).

ASSISTANT EXPERIMENTAL OFFICER (graduate in a biological science, pure or applied, with an interest in field work) in the NEMATODE DEPARTMENT, to assist in work on nematode injurious to cereals and their control.—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/80 (October 15).

CHAIR of PHARMACOLOGY at the University of Singapore.—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 15).

CHAIR of BOTANY.—The Deputy Secretary, The University, Southampton (October 30).

LECTURER (capable of lecturing in general psychology and in psychological testing or psychological theory or vocational psychology, and with a higher degree and some teaching experience) in the SCHOOL of APPLIED PSYCHOLOGY, University of New South Wales, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 30).

CHAIR of ELECTRONICAL ENGINEERING at the University of Tasmania, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 31).

ASSISTANT EDITOR (with a first degree in science, preferably young university graduate wishing to make a career in scientific journalism; previous experience in editing not required) for Nature.—The Manager, Nature, Macmillan (Journals) Ltd., 4 Little Essex Street, London, W.C.2.

ASSISTANT LECTURER (interested in a research career) in the DEPARTMENT of HUMAN BIOLOGY and ANATOMY, for duties which will include teaching of gross anatomy.—Prof. R. Barrer, Department of Human Biology and Anatomy, The University, Sheffield, 10.

BIOCHEMIST, Senior or Basic Grade.—The Secretary, Althincham General Hospital, Althincham, Cheshire.

CHEMIST or BIOCHEMIST (M.Sc. in chemistry or biochemistry, or a B.Sc. honours and several years research experience), to execute research projects concerned with the metabolism of lipids in groundfish and other selected species.—The Director, Fisheries Research Board of Canada, Halifax Laboratory, P.O. Box 429, Halifax, Nova Scotia, Canada.

DISTRICT FOREST OFFICER (with a degree in forestry, and preferably experience of forest administration) to supervise a district; and a FOREST SURVEY OFFICER (with a degree in forestry and field experience in forest surveys and enumeration) in Zambia.—The Appointments Officer, Ministry of Overseas Development, Room 301, Strand House, Stag Place, London, S.W.1, quoting Ref. RO 234/132/01.

ELECTRON MICROSCOPE TECHNICIAN (with experience of electron microscopy or willing to be trained in the running of an electron microscope)—Dr. R. C. Oaking, Department of Botany, University of Nottingham, Nottingham.

FISHERIES OFFICER (with a degree in natural science and postgraduate experience) in Zambia, to assess the potential commercial production of fish by means of a statistical recording programme and to implement development projects concerned with the catching and marketing of fish.—The Appointments Officer, Ministry of Overseas Development, Room 301, Strand House, Stag Place, London, S.W.1, quoting Ref. RO 236/132/01.

**INFORMATION SCIENTIST** (graduate or equivalent) for a small team on information processing and retrieval, dealing mainly with veterinary, entomological and chemical correspondence and reports—The Personnel Secretary, The Cooper Research Station, Berkhamsted Hill, Berkhamsted, Hertfordshire.

**LECTURER (Grade IIa) IN BIOLOGY IN THE DEPARTMENT OF CHEMISTRY**—The Clerk and Treasurer, Paisley College of Technology, High Street, Paisley, Renfrewshire, Scotland.

**RESEARCH ASSISTANT** (preferably with experience in blood/gas measurements) for a new laboratory associated with the Department of Anaesthetics for work concerned with respiratory blood and gas abnormalities—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Project No. 802.

**RESEARCH ASSISTANTS IN THE DEPARTMENT OF MATHEMATICS**—Prof. W. N. Eversitt, Department of Mathematics, Queen's College (University of St. Andrews), Dundee, Scotland.

**RESEARCH ASSOCIATE** (experimental physicist, preferably with some experience of scintillation counting or spark chambers) in the DEPARTMENT OF PHYSICS, for work involving developing and applying a method for investigating properties of the solid and liquid state using nuclear physics techniques—The Deputy Secretary, Westfield College (University of London), London, N.W.3.

**RESEARCH OFFICER, ENTOMOLOGIST** (male or female, with a good honours degree in entomology or zoology with specialised training in entomology, and preferably experience of insect physiology or insect control) at the Hagerman Institute for Trypanosomiasis Research for laboratory and field investigation relating to the control of tsetse flies—The Crown Agents, M. Dept., 4 Millbank, London, S.W.1, quoting Ref. M357/60362/TA.

**SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER** (graduate with a first- or second-class honours degree in biochemistry or chemistry) in the NUTRITION DEPARTMENT, to work on biochemical aspects of nutrient utilization in experimental animals—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berks, quoting Ref. 65/14.

**SENIOR RESEARCH ASSOCIATE IN RADIATION CHEMISTRY** to study biochemical problems of nucleic acids in collaboration with Prof. J. J. Wells—The Registrar, The University, Newcastle upon Tyne.

**SENIOR RESEARCH ASSOCIATE** (Post-doctoral) (physicist, physical chemist or chemical engineer) in the DEPARTMENT OF CHEMICAL ENGINEERING, to investigate gas phase reactions promoted by electrical discharges in continuous flow reactors—Prof. J. D. Thornton, The University, Newcastle upon Tyne.

ORGANIZATION OF SCIENCE AND TECHNOLOGY  
IN RETROSPECT

FOR all that its criticism is restrained, the new Departments and Ministries do not come too well out of the scrutiny which the Estimates Committee has given them in its third report for the Session 1964-65\*, nor particularly does the Ministry of Technology, from the evidence taken before Sub-Committee G. This is the more apparent in that the Estimates Committee is obviously unwilling to press a new Department hard. Concerning the Ministry of Overseas Development, for example, it comments on the relatively small numbers of staff who have been transferred from other Departments surrendering functions to the new Ministry and on the small size of the further staff savings anticipated in some of these Departments. Even so, the view that the savings would only be achieved after a fairly long process of internal re-organization was unacceptable to the Committee.

Here the prodding by the Estimates Committee is addressed to the Treasury, as also is a further comment on the Diplomatic Service. The present reserve of manpower is 280, representing about 4 per cent of the complement of home-based staff; however, this is expected to rise to 435 or about 6.5 per cent of complement, as compared with the 7.5 per cent fixed by the Government following the Plowden Report. The division of this reserve between home and overseas staff was admitted to be somewhat arbitrary and the Estimates Committee recommends that the total strength of the reserve should be shown separately under the heading "Common Services in the Home Organization". It also recommends closer liaison between the inspectorate responsible for reviewing overseas posts at least once every three years and the Organization and Methods Section and that interchange between the two should be encouraged.

To the scientist, as to the technologist, the interest of the Estimates report, however, lies essentially in the observations on the Departments of Education and Science and of Technology, and on the Ministry of Land and Natural Resources. However, the memorandum submitted on behalf of the Minister of Overseas Development describing the organization and staffing of that Ministry is of considerable interest and shows that the staff in some of the special units has been strengthened for 1965-66: that of the Directorate of Overseas Surveys has risen from 515 in October 1964 to 525; of Overseas Geological Surveys from 106 to 123; of the Anti-Locust Research Centre from 66 to 71. There are equally welcome memoranda outlining the functions and organization of the Ministry of Technology and of the Ministry of Land and Natural Resources, but not of the Department of Education and Science. This omission is surprising in that one of the first points of concern to the Estimates Committee was whether a clear line had been drawn between those functions appropriate to the Science side of this Department and those appropriate to the Ministry of Technology.

Staff numbers in the Science side of the Department have risen since 1964 from 107 to 124, mainly through the establishment of the Office of Scientific and Technical Information and of the new Council for Scientific Policy. The Department has now become the accounting Department for the Votes of all four Research Councils—the Medical Research Council, the Agricultural Research Council, the new Natural Environment Research Council and the new Science Research Council. It has been agreed with the Treasury, however, that the accounts of each Council, signed by its chief official, will be annexed to the Estimates of the Department of Education and Science. The Vote for the new Science Research Council, which has a staff of nearly 2,000, amounts to more than £28 million in the current financial year, and besides its responsibility for the support of university research, formerly entrusted to the Department of Scientific and Industrial Research, it is responsible for the control of the Royal Observatories and the Rutherford and Dewesbury Laboratories for Nuclear Physics. Its Headquarters staff is expected to increase from about 200 to 250 during the current financial year, but the increase is partly due to Treasury reluctance to allow recruitment of new staff pending the re-organization.

As a result, the Council faces a temporary shortage of staff which at present prevents it from carrying out more than essential day-to-day functions. The Estimates Committee's hope that this situation will be speedily rectified will be shared by scientists generally, who may also be concerned that in the meantime the present credit squeeze may have made rectification more difficult. Apart from this, however, the Committee, in this report, does not probe further into the functions of the Department of Education and Science. Behind its comments as to the vital necessity of keeping the Department and the Ministry of Technology fully informed of each other's scientific activities may be sensed a certain uneasiness as to how far a broad division of responsibility between basic research and applied research may really be practicable.

Clearly there are likely to be problems and difficulties; however, given goodwill these will be removable, but if there is any cheeseparing and misguided attempt to cut for economy it is likely that they will become accentuated. It is not, however, at this aspect of the Ministry of Technology that the Estimates Committee looked in the first instance, although it is highly critical of its organization which is regarded as top-heavy, even when allowance is made for this being a common tendency in the early stages of a new Ministry. The Ministry is at present divided into six administrative divisions, responsible for financial administration and general policy, and two departments responsible to Controllers and responsible for the scientific and technological aspects of the work of the Ministry. It is intended that there should be a partnership between the two sides of the Ministry with consultation at all levels; of the present Headquarters staff of about 500, 368 were formerly employed at the headquarters of the

\* Third Report from the Estimates Committee together with Part of the Minutes of the Evidence taken before Sub-Committee G on 14th April, 1965, and Following Dates, and Appendices, Session 1964-65—Variations in Estimates. Pp. xiv+80. (London: H.M.S.O., 1965.) 10s. 6d.

Department of Scientific and Industrial Research. A net increase of 190 in headquarters staff is expected by the end of the year and the total staff of the establishments under the Ministry is nearly 5,000.

Where the Estimates Committee is critical is in the appointment of two Controllers as well as two Deputy Secretaries, one of whom is a scientist and a former member of the scientific officer class and was assisting the Permanent Secretary in supervising the laboratories transferred from the Department of Scientific and Industrial Research. The Committee saw no reason for four such posts and shortly before the report was finally agreed learned that it had been decided that there should be only one part-time Controller responsible for all the non-secretariat functions of the Ministry. It still recommends, however, that the Treasury should further examine the need for a second Deputy Secretary.

The Estimates Committee notes that while the headquarters of the Ministry will be in London it is establishing regional offices in each of the newly formed regions as soon as the necessary staff are recruited. Three of these, in Edinburgh, Cardiff and Newcastle, were inherited from the Department of Scientific and Industrial Research, and the main function of the offices is to advise industry on the appropriate sources from which it can obtain advice and assistance. The Industrial Liaison Service, which originated in Scotland, is also being expanded and provision in the current year is expected to be £63,000 as against £35,000 in 1963-64. The Committee did not look closer either at this Service or at the functions of the regional offices; in this field of information and advice there appears to be an inherent possibility of overlap with the work of the Office for Scientific and Technical Information within the Department of Education and Science: here again close contact between the two Ministries seems essential.

More serious, however, is the Estimates Committee's criticism of the approach of the new Ministry to what Mr. Cousins has insisted on as one of its most important new functions—that of initiating technical and economic studies in depth of selected industries and processes to determine whether action is needed and if so in what direction. The four such studies so far announced involve the electronics and telecommunications industries, which were formerly sponsored by the Ministry of Aviation and the Post Office, respectively, and the computer and the machine tool industries, both formerly sponsored by the Board of Trade. The Committee was not satisfied that the teams being set up for these initial studies had the appropriate membership or that they were being set up with sufficient speed; the minutes of evidence suggest that on both points the Estimates Committee's comments are very mild. That some at least of the investigators should have had up-to-date experience of the industry in question seems a pre-requisite: that they should have been drawn mainly from within the Government service seems as indefensible as the dilatoriness with which the teams are being appointed.

Nor is this all. Apart from the uncertainty which such procedures are likely to cause in the industries concerned, the Estimates Committee has doubts as to the work of these appraisal teams overlapping or duplicating studies which are being carried out under the aegis of the Department of Economic Affairs. It would appear that the Committee was not entirely satisfied by the assurances it received as to close contact and liaison between the Ministry of Technology and the Economic Development

Committee, which is itself studying the economic performance of the machine tools industry.

The debate on the Civil Estimates for the Ministry of Technology in the House of Commons on July 14 was held immediately before the Estimates Committee's report was published, but Mr. Cousins scarcely touched on the points raised in this report dealing with the position of the Atomic Energy Authority and the National Research Development Corporation. Of the Authority's Trading Fund, he stated that sales of fuel elements, electricity and isotopes amounted to some £30 million per annum, and of hovercraft developments that some ferry services using the smaller craft were already running, while firm orders had been received for at least seventeen and possibly eight more. Generally the debate was unsatisfactory and inclined to make party points in spite of several suggestions that technology should not be a matter of party politics. However, both Sir Lionel Heald and Mr. R. Sheldon raised the question of the delay in starting the new reference library for science and invention, as well as raising the question of its location. Sir Lionel was concerned that the Patent Office should remain in London. The best part of the debate was, in fact, that in which questions of the structure of Government generally were discussed rather than the particular organization of the Ministry of Technology.

The Estimates Committee in its report also considers the Ministry of Land and Natural Resources, and while the memorandum from that Ministry, already noted, refers to the existence of a Natural Resources Planning Unit, it is curious that the Committee does not comment on the need for appropriate liaison and contact with both the Ministry of Technology and the Department of Education and Science, within the orbit of which falls the newly established Natural Environment Research Council (of which the Nature Conservancy now forms a Committee). The potentialities for overlap and confusion are as implicit as they are between the Ministry of Technology and the Department of Education and Science.

While the Estimates Committee is not entirely happy about the present arrangements, its misgivings find expression in regard to two matters only—staff and the sharing of responsibility for water between the new Ministry, the Ministry of Housing and Local Government and the Welsh Office. Welcoming, however, the statement of January 19 that the present arrangements for Ministerial responsibility are to be kept under review to see whether experience in implementing them calls for any change, the Committee makes no specific comment other than that such evidence as came before it suggests that more experience will be needed before a final decision can properly be made about ministerial responsibility for water.

On staff, it is noted that about half the present staff of 150 was seconded to the Ministry along with their former work; the total is expected to increase by 20 by the end of the financial year, partly to set up the Land Commission, partly to strengthen the section dealing with the Ministry's responsibility for water, and partly to staff the expanding work of the Natural Resources Planning Unit, which is working in close association with the new Natural Resources Advisory Committee. It is visualized that this Unit will have an administrative scientist and a professional scientist as joint heads, but it does not appear from the evidence that the structure is much more than tentative, although it is expected that the Natural Resources Advisory Committee, of which Sir Dudley

Stamp is chairman, will advise on the extent to which use could be made of the universities and other institutions. At present the established staff of the Department are on loan from their former Departments, and although the arrangement is regarded as temporary it remains to be seen whether the Department will become large enough to provide adequate opportunities for a career.

The Estimates Committee does not think that this situation should be allowed to continue for any appreciable length of time and, while the point is not pressed, the report leaves the general impression that more regard might well be paid to the point of view of staff in other new Ministries. Conditions of service can make all the difference to efficiency and enthusiasm at a time of change and experiment when a certain amount of flexibility is desirable; as a consequence some uncertainty is unavoidable. What above all emerges from this survey of the new Ministries is the undesirability of making some of the arrangements other than tentative until they have been firmly proved by experience. It is equally clear that the misgivings with which some of them are regarded are well founded and not to be dismissed as party prejudices. The Ministries would do well to heed the restrained criticism of the Estimates Committee and to respond to constructive suggestions. Especially in this matter of staff, they should spare no pains to establish full confidence and to provide the conditions of service which will encourage full and effective co-operation between departments and sections and the keenness and interest that are vital where science and technology are concerned. To persist in impeccable self-satisfaction such as Mr. Cousins presented to the House of Commons on July 14 would be fatal.

## DESALINATION OF SEA WATER

### Fresh Water from the Sea

Proceedings of the International Symposium held in Milan by Federazione Delle Associazioni Scientifiche e Tecniche and Ente Autonomo Fiera di Milano. Edited by A. Giralli. Pp. xxii + 179. (Oxford, London and New York: Pergamon Press, 1965.) 60s.

WITH the increase in world population, the spread of urbanization with its accompanying industrial development, as well as the higher standard of hygiene in the emergent nations, the demands for water both potable and industrial are ever on the increase. The supply, on the other hand, by precipitation from the sky is limited with a yearly average of some 750 mm. It is thus natural that the attention of several nations is being drawn to the problems of water conservancy and the production of potable water from the sea and other brackish or otherwise unsuitable waters. Indeed, water shortages are already manifest over many regions of the globe, and in all industrial areas water availability is fast becoming a factor of major importance in the location of factories. It has been computed that it takes 65,000 gal. of water to make a ton of steel; 5,000 gal. for every ton of sulphuric acid; while a single copy of one American Sunday newspaper consumes half a ton of water, and no less than 5 tons of water are required to make the synthetic fibres for a summer suit.

Since the production of potable water confronted shipping lines at an early date this problem has received more attention than that of water conservancy. Some seventy per cent of the annual precipitation is entirely wasted, either by evaporation or passage into drains, and eventually into rivers; thus it is to be hoped that economies in this field can be effected.

*Fresh Water from the Sea* gives an account of a symposium held in Milan in which the state of development of

desalination in a number of countries is described. These include Holland, Japan, Germany, Great Britain, Italy, Israel and the United States. Some of the conclusions result from a world-wide survey under the aegis of the United Nations Department of Economic and Social Affairs, and a very full bibliography completes the volume.

The majority of processes involve distillation, but the early form of direct heating stills has given place to flash methods as well as that using a falling film or compression with forced circulation for the vapour. Interesting formation is given by the authorities in the different countries on the chemical engineering, power sources, and distribution problems involved in the construction and operation of such plants.

While reverse osmosis is theoretically probably the most efficient process from thermal considerations, no effective plant has been constructed as yet on these lines. On the other hand, several plants utilizing electro-osmotic methods are in operation and on a relatively small scale at least are almost competitive with distillation processes. The successful development of such plants has been made possible by the fairly exhaustive enquiries which have been made into the properties of ion-exchange membranes and their technical production on a large scale. It seems doubtful whether these electrolytic plants are economic in the production of pure water, but these, combined with a subsequent treatment by ion-exchange resins, offer some hope of a successful method. The more recently developed weakly acid and weakly basic resins present the possibility of extending the ion-exchange methods from the treatment of brackish to saline waters.

Brief mention is made of some other methods by which conversion of salt to potable water might be achieved on a large scale: these include fractional crystallization of ice and its separation by centrifugal methods, the utilization of cryohydrates for a similar purpose and finally the use of solar energy for evaporation.

The various sections are written in English, German and Italian and give very readable accounts, containing but a minimum of highly technical material, of the progress which is being made in this at present important and, in the near future, very necessary field of human endeavour.

## EDUCATION AND VALUES

### Education and Values

Essays in the Theory of Education. By G. H. Bantock. Pp. 182. (London: Faber and Faber, Ltd., 1965.) 25s. net.

*EDUCATION and Values* consists of a collection of essays which concern contemporary discussions and controversies in education. The author, whose outlook is predominantly literary, bases his ideas on T. S. Eliot's attempt to define a culture for the twentieth century. Prof. Bantock has an Ayer-like consideration for the nature and meaning of words, he shows a close concern for the language of education discourse and reveals some of the ambiguities and inadequacies of present-day formulations.

The subjects treated include the relation of education and society, the problem of freedom in education, the influence of educational sociologists and the role of literary intelligence, where it exists, in assisting thought in education. Of particular interest is Prof. Bantock's diagnosis of what is the trouble with so many investigations which are glorified with the title of "Research in Education". This short section could have been expanded with advantage, for his criticisms could have been extended to many investigations of a sociological nature. This is not to say that we expect the same degrees of accuracy, which are commonplace in the physical sciences, but that there must be a more intelligent assessment of subjective factors, some of a subtle nature, which are involved in researches in education and sociology. More is required than an application of suitable statistical techniques.

"The discipline of social research has not succeeded in creating a specialized language of its own; indeed, in view of the nature of its subject matter is unlike that of the physical sciences in that it deals with what already has meaning apart from that assigned to it by the scientist, it is that the social sciences will never succeed in creating a fully technical vocabulary. Since, then, the statement of research topics usually involves the use of words common in everyday usage, the prime requisite in the consideration of research problems is the conceptual clarification of the terms employed, at least to the extent that possible ambiguities are cleared up or that ostensive definitions are offered. It is disturbing to find how little modern philosophical techniques of linguistic analysis and clarification have affected our thinking about social science research; yet as a preliminary to any such research it is important at least to decide what questions involved are really conceptual and what empirical."

If Prof. Bantock's criteria are applied to much which has passed as research in sociology and education and has been published, the value of the results is seen in a much dimmed light; indeed, if it is seen at all. No doubt the large advertising firms base their schemes and expenditure on more skilful investigations. The remedy is not so much to take a leaf from the book of the more successful research scientists in the physical and so-called 'applied sciences', but to develop a more critical and subtle series of experimental techniques peculiar to the social sciences, beginning by clearing the waste-land, as Linnaeus did many decades ago in biology, by proper semantics which lead to more precise methods of description and classification.

The greater part of Prof. Bantock's book deals with the aims and philosophy of education. This is stimulating, timely and few would contradict him. His chapters constitute a warning against the technocratic state, when everybody therein ceases to be a person, as many do even now, and becomes a number of holes punched in an IBM card, stored in some state-controlled records office.

W. L. SUMNER

## IMMUNOGLOBULIN TURNOVER IN MAN

Metabolism of Human Gamma Globulin.

By Stig Bryde Andersen. Pp. x+139. (Oxford: Blackwell Scientific Publications, 1964.) 30s. net.

**A**NTIBODIES in human serum are known to be associated with at least 3 distinct but related immunoglobulins ( $I_g$ ); these are now generally referred to as  $I_gG$  (7 S  $\gamma$ -globulin),  $I_gA$  ( $\gamma_1A$ -globulin) and  $I_gM$  (19 S  $\gamma$ -globulin). These proteins may carry identical combining specificities but their biological effects are modified by differences in their distribution in the body. For example, the three classes of antibody occur in widely different relative amounts in various tissue fluids and secretions; they also vary in their transplacental passage from maternal to foetal circulations and in their capacity to attach to various tissues, including the skin. In addition, the immunoglobulins differ in their rates of overall synthesis and catabolism, and in their sequence of synthesis during the course of development and after antigenic stimulation. In pathological states the different immunoglobulins may react independently and this is seen most strikingly in proliferative disorders of the lymphoid system such as myelomatosis and macroglobulinaemia.

A comprehensive account of what is known of the distribution and metabolism of immunoglobulins in health and disease would form a welcome contribution to the immunological literature. Dr. Andersen's book is far more limited in scope. He describes results obtained with one class of immunoglobulin, namely  $I_gG$ , using a single experimental technique to measure overall distribution and turnover in a large series of patients. The labelling of  $I_gG$  with

<sup>125</sup>I was carried out by techniques which have been developed and meticulously tested by Dr. A. S. McFarlane, and the quantitative interpretation of data is based on analytical methods elaborated by Dr. Christine Matthews. An appendix contains an outline of several alternative methods of analysis and includes a discussion of the significance of the iodide pool in calculations of iodine labelled protein turnover. Results are presented for hospitalized patients considered normal and for two other groups of subjects with increased and reduced levels of  $\gamma$ -globulin respectively. The findings re-emphasize the fact that hypergammaglobulinaemia is always associated with an increased rate of  $\gamma$ -globulin synthesis and seems never to result from reduced catabolism. Similarly, hypogammaglobulinaemia is usually the result of underproduction, although it may be due to abnormal loss of  $\gamma$ -globulin through kidney or gut sometimes aggravated by an increased rate of  $\gamma$ -globulin catabolism.

This book does not constitute a down-to-earth practical guide for anyone wishing to set up the techniques employed in labelled protein turnover experiments. However, there is a detailed bibliography and the data illustrate the clinical applications of a method which has elucidated some aspects of the exceedingly complex problem of  $\gamma$ -globulin metabolism.

S. COHEN

## THE SMOKER'S DILEMMA

Smoking, Health and Personality

By Prof. H. J. Eysenck. Pp. 166. (London: Weidenfeld and Nicolson, 1965.) 25s. net.

**T**HE hypothesis that lung cancer and the habit of smoking cigarettes may both be due to a common genotype was first suggested by R. A. Fisher. Eysenck has now pressed into the service of this 'constitutional hypothesis', as it is known, the assumption that the common genotype is an extraverted personality. He defines an extravert as a person who gives appropriate answers to such questions as: "Do you usually stay in the background at parties and get-togethers?" "Do you find it hard to really enjoy yourself at a lively party?" "Can you usually let yourself go and enjoy yourself a lot at a gay party?" "Do you hate being with a crowd who play jokes on one another?" and he claims that strain differences in rats similar to those in man can be established with respect to extraversion and introversion. (One wonders how many housewives and boilermakers have sufficient time to go to enough parties to enable us to decide whether they are extravert. It is also rather hard to imagine how a rat is expected to conduct himself at a gay and lively get-together or what a rat's joke would consist of.)

By his dogma that the lung cancer linked with cigarette smoking is due to innate extraversion, Eysenck would have us believe that the genetic composition of many countries, especially in urban areas, has changed uniformly towards extraversion during the past half-century. Furthermore, he assures us that "men are very slightly more extraverted [than women] although the difference is too slight to mention". If so, and if lung cancer is a disease of extraverts, why should the lung cancer sex ratio have changed from 1.5 to 1 in 1930 to more than 6 to 1 in 1961?

He begins with a discussion of methods of study in microbiology and bacteriology, topics in which it is unusual for a psychologist to display special competence. This is followed by an evaluation of epidemiological investigations which, he asserts, "can give wrong conclusions as readily and as easily as correct ones"—a dictum which is demonstrably either trivial or untrue. He goes on to consider alleged criticisms of the smoking-lung cancer hypothesis. Here, guidance from a medical statistician would have helped him to avoid an error in stating the difference between expected and observed

mortality from lung cancer. On p. 40, when it is a question of a correlation between smoking and lung cancer, Eysenck (quoting Thurstone) describes a correlation coefficient as a confession of ignorance. On p. 80, when referring to his questionnaires, he declares approvingly that the similarity between two traits is assessed by "a mathematical technique known as correlation". Moreover, while he insists that correlation is no evidence of causality when dealing with 'smoking' he has no hesitation in interpreting correlation as causality when incriminating 'smoke'. For in Chapter 7 he seems to abandon extra-version and brings forward a "logical indictment of smoke". But he soon leaves smoke and comes down in favour of insufficient enzymatic fermentation in the processing of cigarettes as the cause of lung cancer.

As for breaking the habit of smoking, the method to use is "quite obviously to have punishing consequences follow the smoking of a cigarette *before* the rewarding consequences have any chance to establish themselves". This can be achieved by the aid of an apparatus called a ventilator heater which blows hot air at the smoker "while he pronounces the auto-suggestive phrase 'I want to give up smoking'". Eysenck concludes: "There is no reason why society should be allowed to poison our lungs, but every reason why we should be allowed to poison our own if we want to".

JOHN COHEN

## STIELTJES'S MOMENT PROBLEM

### The Classical Moment Problem

And some Related Questions in Analysis. By N. I. Akhiezer. Translated by N. Kemmer. (University Mathematical Monographs.) Pp. x+253. (Edinburgh and London: Oliver and Boyd, 1965.) 70s.

EQUIMOMENTAL systems show that different line-density distributions may have the same mass, centroid (first moment) and moment of inertia (second moment). Stieltjes (1894) asked if a knowledge of all the higher-order moments would allow and imply a unique density; more precisely, given a sequence  $\mu_k$  of numbers, can a non-decreasing function  $\sigma(u)$  be found such that:

$$\int_0^\infty u^k d\sigma(u) = \mu_k. \quad (k=0,1,2, \dots)$$

The problem established the concept of the Stieltjes integral, and gave scope for Stieltjes's mastery of continued fractions. A little earlier, Tehebychev (1873) had discussed a similar problem: given the length, mass, centroid and second moment of a line segment, to find bounds for the mass of any sub-segment; more precisely and more generally, given:

$$\int_a^b u^k f(u) du, \quad (k=0,1, \dots, n-1)$$

to determine bounds for:

$$\int_a^b f(u) du$$

for variable  $v$  in  $(a, b)$ . Tehebychev's interest lay chiefly in the probability application.

Various extensions can be made: the interval may be replaced by a set of points, or extended to  $(-\infty, \infty)$ . Essentially, the main questions are: Does a solution exist; if so, how many significantly different solutions are there; and how can they be constructed?

The field remained relatively unexplored until just after the First World War, when in a burst of activity the first full discussion and solution were given by Hamburger, quickly followed by Nevanlinna, M. Riesz, Hellinger, and Carleman. The problem was seen to have connexions with many branches of analysis; thus Hausdorff, in two masterly papers, showed the relation with summation methods. Later, the development of functional analysis and linear

operators provided new ways of looking at the problems, and new fields for applications and extensions. While many questions remain, so much has been done to codify the theory that the time is ripe for a broad survey. Prof. Akhiezer, who has himself contributed largely to recent progress in this domain, provided such a survey in his 1961 book, of which we now have a welcome translation in the new Oliver and Boyd "University Mathematical Monographs". After a necessary preliminary chapter on sequences and the related orthogonal polynomials and Jacobi matrices, he gives the main results of Hamburger, M. Riesz, and Nevanlinna, often using the present-day language of abstract spaces and functionals, and then deals with the moment problem as an instance of the spectral theory of operators; here the reader must know at least the elements of modern operator theory. The final chapter discusses a trigonometric moment problem, related to Carathéodory's problem about the conformal mapping of the unit circle on a half-plane when a correspondence between two point-sequences is prescribed; this leads on to certain continuous analogues of the moment problem.

The reader who is content to study the main text will obtain a sound and precise knowledge of the principal themes; but to master the subject he will be well advised to spend time and effort on the "addenda and problems" which complete each chapter, for these are not drill examples, but serious (and sometimes difficult) developments and extensions of the main text, relegated to a secondary position simply to reduce bulk. The young research student who appreciates abstract analysis while not despising manipulative skill should find here matter and questioning to his taste.

T. A. A. BROADBENT

## KANTIAN STUDIES

### Experience and Its Systematization

Studies in Kant. By Nathan Rotenstreich. Pp. vii+178. (The Hague: Martinus Nijhoff, 1965.) 21 guilders.

IN this work, the traditionally high standard of the house of Martinus Nijhoff is well maintained, and the author need have no reservations about the desirability of offering a selection of 'pivotal issues' which have become definitive for Kantian scholars. The master spent practically his whole life in his native city of Königsberg analysing empirical knowledge, and erecting on this ratiocination a systematic structure, which, at least in principle, involves ethics and aesthetics. It is a measure of the stature of this intellectual adventure that only comparatively recently has the suggestion been made that these axiological studies might eventually become subject to the power of symbolic logic. If ever they do, then Prof. Rotenstreich will have provided a suitable springboard for the transition, since the leap could scarcely be made from the *Critiques* in their original form, including, as they do, a number of inconsistencies and ambiguities.

For Kant, formal or general logic is almost a calculus for thought without regard to the differences which its objects present, whereas transcendental logic deals with origins—actually of our *a priori* knowledge of objects. This is the point of contact with the Husserl school, and the development of phenomenology, including the realization of empathy. If there is one word which expresses this connexion it is *Anschauung*, or intuition. Kant epistemologically allows time preference over space, although in terms of "true no matter what" they are supposedly equal. If, on the other hand, the criterion is ontological (following Parmenides and Spinoza), then the order is reversed. Twentieth-century physics was in fact to eliminate this distinction in the well-known relativistic prophecy of Minkowski. All of which goes to show the value of a re-assessment of Kant's technique.

In a discussion of the primacy of practical reason, it appears that immortality and God are not implied by

action, whereas duty must contain certain empirical concepts. Strangely parallel with this, it may be mentioned that there is a recorded conversation between F. W. H. Myers and George Eliot (when her *Middlemarch* had just appeared in book form), which took place in the Fellows' Garden at Trinity College, Cambridge. She pronounced God to be inconceivable, immortality to be unbelievable, and "yet how peremptory and absolute" was duty. Whatever may be thought of the first two assertions, it is manifest that Kant's practical sense was subconsciously underlying the Victorian emphasis on 'must'.

The appendix may be styled, in brief, 'from Schopenhauer to Heidegger', and contains an appraisal of the position of the Marburg school, and a reference to Vaihinger's philosophy of *Als ob* ('As if'). Off the mainland of Europe, the latter discipline has been sadly neglected, to the detriment of our grasp of certain fundamental aspects of natural science. Kant's purpose is moral, whereas Vaihinger's aim is practical. His fictions are conscious fictions, forged to secure orientation.

Such questions as these, and many others, are well displayed. There are a few failures to achieve idiomatic English, but considering how closely the author's thesis is argued, the reader gets a clear picture of the Kantian mode.

F. I. G. RAWLINS

## FOUNDATION OF MODERN NETWORK THEORIES

### Tensor Analysis of Networks

By Gabriel Kron. Pp. xxix+635. (London: Macdonald and Co. (Publishers), Ltd., 1965.) 70s. net.

DR. KRON has been, and to a certain extent still is, a centre of controversy, but his genius is now acknowledged and his reputation firmly established. The experience of many years has proved the immense value of his pioneer work to engineering practitioners and teachers as well as theorists. His recent researches are too advanced for most engineers to understand, and some years must elapse before an assured and durable assessment can be made of his total contribution to knowledge.

His first imaginative proposal, made about 30 years ago, was to apply the tensor calculus to electrical engineering. It was brought to the attention of his fellow engineers by a series of articles in the *G.E. Review* entitled "The Application of Tensors to the Analysis of Rotating Electrical Machinery", later revised and republished in book form. Meanwhile he had written *Tensor Analysis of Networks*, a book published shortly after the series ended. Kron refers to these two books as *A.T.E.M.* and *T.A.N.*; they form the basis of all his subsequent work. Their publication immediately evoked vehement and extensive criticism, a little of which was perhaps justifiable, for it could scarcely be expected that so unusual a work would command universal assent; we cannot all accept Kron's approach in its entirety. But much of the criticism was destructive, ill-informed and grossly unfair. Even among those who approved and admired the work there were some who regarded it as an academic exercise of no practical value. If this had been so, the two books would have been isolated publications, whereas they proved to be forerunners of many books by various authors on this topic. For what eventually vindicated Kron and established his high reputation was the belated realization that his methods had enormous practical and pedagogic usefulness. They worked. Many experienced engineers now believe that the application of tensors to electrical engineering was a major advance that ranks Kron with Steinmetz and Heaviside.

Clearly both *A.T.E.M.* and *T.A.N.* are important books and should be available to all who propose to study this subject. They were published in the United States and unfortunately have been out of print for some years. It is therefore gratifying to see *T.A.N.* reproduced by British

publishers. As it is a reproduction without revision it is probably sufficient to say that its title effectively indicates its scope. The author includes an astonishing amount of material, so much that the beginner may well be bewildered by the wealth of information offered. Kron says that this volume scarcely scratches the surface of the vast possibilities in the subject, but the scratch is deep enough for most of us to be going on with.

The only new part in the book is the 16-page introduction included at the expense of the original introduction. I should have preferred to see the retention of the original with the new introduction added at the end as an epilogue, for two reasons: one is that for new readers the old introduction is understandable without knowledge of what is in the rest of the book, whereas the new one is not; the other is that, for all of us, both are of great interest, and comparing them brings out the progress of thought over a quarter-century. The new introduction looks to the future, and Kron has some scathing things to say about those who confuse linear graphs with electric networks, which is something like confusing diagrams with vector space configurations, or matrices with tensors.

Kron's achievements assure us of his genius, but the new introduction reveals parts of his personality. Among other traits we see a man gifted with unusual imagination, great industry and intellectual courage of a high order. Both opponents and admirers should note that he expressly disclaims mathematical rigour in his proofs. Like Heaviside, he is guided by an amazing intuition. His aim, he says, is to get definite answers to definite engineering problems; he rightly claims that his methods do just that.

The publishers are to be commended for their enterprise in republishing this notable book; I hope that its reception will encourage them to do the same with *A.T.E.M.*

W. J. GIBBS

## PSYCHOSOMATIC RESEARCH

### Psychosomatic Research

A Collection of Papers. By J. J. Groen *et al.* Pp. x+318. (London and New York: Pergamon Press, 1964.) 80s. net.

THE psychosomatic hypothesis takes two forms. According to one, certain types of people, showing measurable personality traits, are more likely to suffer from specified diseases than others. According to the other, certain life experiences of an emotional kind are liable to predispose people to develop certain specified diseases. It is widely believed that these psychosomatic theories are of recent origin, and spring from the work of Freud and the early psychoanalysts; this is not true. Hippocrates put forward explicitly views of a psychosomatic kind and these were widely held in the Middle Ages; indeed psychosomatic theories were flourishing during the first half of the nineteenth century and were applied even to such disorders as cancer and tuberculosis. Pasteur and the success of scientific medicine temporarily eliminated these hypotheses, but more recently they have been re-introduced by psychiatrists, although even now their reputation among critical experts is not high. This low standing of psychosomatic research is due in part to the great difficulties involved in measuring personality or quantifying the life circumstances which are supposed to contribute to the development of disease; in part it is due to the low level of rigour and experimental expertise shown in many published investigations.

*Psychosomatic Research*, edited by an eminent Dutch physician who has done much work in this field, is a set of reprinted articles from his laboratory at the Wilhelmina Gasthuis in Amsterdam, originally published in a variety of journals by him and his collaborators. Groen explains at the beginning of the book that "progress in modern medicine was largely due to the introduction of exact methods of thinking, the application of physics and

chemistry to the study of disease, and the introduction of an experimental and quantitative approach to clinical problems. The human mind, however, . . . had not been similarly explored and it was chiefly through the lack of suitable methods of research that psychiatry had lagged behind". This is an interesting statement because it reveals an unawareness on the part of the author that many experimental and quantitative methods for the study of the mind have in fact been developed by psychology, and that the failure of psychiatry to become scientific has been largely due to the fact that these methods have not been applied.

Groen and his colleagues have tried hard to overcome the difficulties of their task, and to apply experimental and quantitative methods, but they have done so only in a half-hearted manner, and the level of the work is not always as high as it should be. Sometimes, as for example in the study by Valk and Groen on the electric resistance of the skin during induced emotional stress, the statistical treatment of the data is too tenuous to be acceptable, the experimental arrangement is rather primitive, and much of the argument is rather anecdotal. It is true that the research was done more than fifteen years ago, and that it would have been nearer the average standard of experimentation then than it would now, but in a book published in 1964 one must judge the contents in terms of the present level of sophistication. In another paper, Barendregt has studied the effect of group psychotherapy by using the Rorschach test, which in spite of the ingenious way in which he has managed to overcome some of the inherent difficulties and subjective weaknesses of this projective device can scarcely claim to be an appropriate tool for experimental analysis. In addition the statistical argument presented is faulty; three hypotheses are tested of which two are clearly insignificant even on a one-tailed test. One is barely significant at the 1 per cent level on the one-tailed test, but being one out of three must be regarded as not supported by the evidence. Barendregt quite incorrectly combines the *P* values for all three hypotheses and arrives at the conclusion that his data reject the null hypothesis.

It would be wrong to conclude that there is nothing of interest in this book. Groen and his collaborators have tried hard to lift the subject of psychosomatic research from the quagmire in which psychoanalytic speculation has landed it, and many of their investigations are intriguing and suggestive. It is questionable whether they are important enough to merit resurrection and publication in book form at the rather high price of 80s.; it seems likely that only specialists will feel that whatever the price this book is essential to them.

H. J. EYENROCK

## UNCONTROLLED INSECT PHYSIOLOGY

### The Physiology of Insecta

Vol. 2. Edited by M. Rockstein. Pp. xvi+905. List Price 235s.; subscription price 211s. Vol. 3. Pp. xiv+692. 178s. 6d. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.)

THESE two weighty volumes complete Rockstein's book on *The Physiology of Insecta*, the first volume of which was published in 1964 (*Nature*, 205, 116; 1965). I cannot claim to have read the 1,600 pages in the critical manner which would have been a pleasure with a shorter book; but the same difficulty has beset the editor, who has failed adequately to collate the various contributions. This shows itself most obviously in the index, which not only mis-spells the names of many insects, but often lists the same insect under two generic names. There is no indication that *Anagasta* is the same insect as *Ephestia*, *Lucilia* the same as *Phaenicia* and so on. In the text identical data for a species are quoted twice, under differ-

ent names, and the larva and adult of the same species are under different genera in the same table (Volume 3, p. 116, Table 1). One author, whose name is unaccountably printed in italics in the text, has also been elevated to insect rank and appears with them in the index to Insecta. Indexing deserves more serious consideration than this if a work is to be used for handy reference. Separate indexes to authors, insects and subjects are a good feature; a combined subject index in the last volume would have partially overcome the disadvantages of the awkward subdivision of the work. It is a pity that the bibliographies do not include titles: the time saved the reader justifies the increased cost.

The editor has grouped his subjects into three sections, which unfortunately do not match the volumes. Biology, development and ageing (Section A) was finished in Volume 1, which also had seven chapters from Section B on the insect and the external environment. Volume 2 completes this part with six further chapters. Markl and Lindauer consider insect behaviour in 130 pages, of which as many as 50 are devoted to the mechanism of orientation. Lindauer then follows this with 65 pages on social communication. The chapters on migration by Johnson, terrestrial locomotion by G. M. Hughes, swimming by Nachtigall and flight by Pringle are all much shorter.

Section C, "The Insect and the Internal Environment—Homeostasis", has eight chapters in Volume 2 and eleven in Volume 3. Huber writes on neural integration and Graham Hoyle discusses the neural control of skeletal muscle. Hoyle's Fig. 1a on p. 410 is quite unnecessarily repeated by Maruyama on p. 453 in an article on the biochemistry of insect muscle. Maruyama apologizes for not discussing the controversial topic of the mechanism of muscular contraction.

Sacktor's 100-page chapter on the energetics and metabolism of muscle uses, without any explanation, all the usual biochemist's abbreviations for the many substances which come into his story. This seems unwise if the book is to be useful to the general reader. Chetfurka follows in a similar vein with two long chapters on the metabolism of carbohydrates, nitrogenous and lipid compounds. House completes a useful account of nutrition and digestion in less than a hundred pages.

Volume 3 deals with various aspects of blood in three chapters by Jones, Florkin and Jeuniaux, and Grégoire. There is an informative chapter on salt and water balance and excretion by Stobbs and Shaw. Briggs writes on immunology and Perry on insecticide resistance. Locke, Hackman and Ebeling have three chapters on the cuticle. All use data from Baker's study of the waxes of the Mormon cricket. Ebeling quotes this in detail in his text and the other two each have tables summarizing it to different degrees. The work ends with two chapters on respiration by Miller and by Keister and Buck.

Most of the illustrations are good and some useful new diagrams are included. Some have been reduplicated and some (for example, Volume 3, p. 30) show nothing and should have been replaced by drawings.

The book is extremely patchy. Contributors cannot have seen the chapters by their co-authors on closely related topics. The duplications and omissions show that the editor has exercised quite insufficient control. The work as a whole has the character of *Recent Advances in Insect Physiology*. It cannot stand as a definitive text of reference. Even though many of the articles are individually excellent they do not between them cover the field adequately.

A book of this length and character cannot be recommended for student reading. Research workers whose interests are covered by one or more chapters will find it helpful. The articles would, however, have been more useful separately than bound up in these three volumes, which together weigh 9.5 lb.

G. C. VARLEY

### Nuclei and Radioactivity

By G. R. Choppin. Pp. ix + 150. (New York and Amsterdam: W. A. Benjamin, Inc., 1964.) Cloth back, 5.50 dollars; paper back, 2.15 dollars.

*NUCLEI and Radioactivity* is one of a series of short monographs primarily intended for inclusion in a first-year university chemistry course. It covers the field commonly described in the United States as nuclear chemistry—nuclear forces, radioactivity, the radiations and their detection, accelerators and the production of radioactive species, and the study of nuclear species and reactions, including fission. The final chapter, however, is devoted to an outline of the applications of radioactivity in chemical, biochemical and technical studies. Brief appendices on the biological effects of radiation and a table of isotopes are included, as well as a glossary.

All this is a great deal to attempt within such a brief monograph. Inevitably much must be discarded and opinions will differ on what can be regarded as expendable. A chapter is devoted to fission, culminating in an outline of the principles of a reactor; yet the delayed neutrons are not mentioned and the impression is given that an uncontrolled reactor will explode like a bomb.

An outline of nuclear spectroscopy, the shell model and of the different modes of nuclear reaction is included; but the procedures by which decay schemes are unravelled are not described and one has an uncomfortable feeling that some students will find that nuclear chemistry is too completely disconnected from the rest of their subject.

Nevertheless, it is certainly desirable that the chemistry graduate should be familiar with the whole of the contents of this book and I am by no means sure that this is yet true in Britain. A. G. MADDOCK

### Teilhard de Chardin

*The Man and his Theories.* By Abbé Paul Grenet. Translated by R. A. Rudorff. (Profiles in Science.) Pp. 176 + 15 illustrations. (London: Souvenir Press, Ltd., 1965.) 21s.

THE Abbé Grenet has written a concise and well-balanced book and has set out the many strands of Teilhard de Chardin's energy and intellect. The author deals with his scientific work, his philosophy and his theology. He shows how the writer of *The Phenomenon of Man* and *The Future of Man* exercised such a great influence in the field of prehistoric archaeology. No doubt Teilhard has been extravagantly praised in recent years: "He has emerged as one of the century's most remarkable prophetic thinkers, an Aquinas of the atomic era" and "some people rank him as the greatest thinker-prophet of the twentieth century".

Although Teilhard himself seems to have arrived at a satisfactory synthesis of his science, philosophy and theology, his superiors in his Catholic order seem to have been less happy about some facets of his thought. He was ordained a priest in 1911. He taught physics and chemistry, but his true interest was in geology and palaeontology. In 1923, he was sent to help with excavations in Central China, where he found traces of Palaeolithic man, a prelude to the discovery of Peking Man six years later. From that time much of his life was spent in China, and all his scientific work and his prehistoric studies were related, through his deep religious feeling, to the origin and future of mankind. The theological implications of his reflections on evolution led his superiors to forbid the publication of much of his non-technical work. As a Jesuit priest he remained obedient to his order but nevertheless he freed and inspired the imaginations of others working on palaeontology and prehistoric archaeology. He was able to build up the strongest personal relations with all the major workers in his field. The citation of his promo-

tion as an officer of the d'Honneur read: "in the realms of palaeontology and geology he may now be considered one of the glories of France". Teilhard de Chardin concludes with some revealing extracts from his own writings, commencing with letters from the War front in 1917. It is well illustrated and has been ably translated by R. A. Rudorff. W. L. SUMNER

### Stability of Nonlinear Control Systems

By Solomon Lefschetz. (Mathematics in Science and Engineering: a Series of Monographs and Textbooks, Vol. 13.) Pp. xi + 150. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 60s.

STUDY of the stability of a linear dynamical system with linear control is a fairly well-organized domain, since the full linearity permits use of standard algebraic techniques. But with non-linear control, even of a linear system, these techniques lose their efficacy. Here, thanks to Soviet mathematicians in the first place, the direct method of Liapounov has been exploited; some five years ago, the Rumanian mathematician Popov produced two remarkable theorems on sufficient conditions for stability, using convolution and Fourier transforms. This has prompted further work in the United States, with Lefschetz himself, Kalman and LaSalle making important contributions.

Lefschetz gives a terse description of this work, the high points being Popov's theorems and some complements; the book has the master's customary vitality, illuminating phraseology, and unerring selection and emphasis of critical points in the argument. Of course, the reader is expected to be sophisticated, and reasonably industrious in supplying details; but knowledge assumed is not more than the amount of matrix theory and transform methods normally contained in a good honours degree course. Thus the young mathematician, contemplating research in a field which is likely to yield large dividends, should find the present monograph an efficient survey and guide, bringing him right up to the front line of advance. ### The Structure of Atoms

By J. J. Lagowski. (Classic Researches in General Chemistry.) Pp. vii + 120. (Boston and New York: Houghton Mifflin Company, 1964.) 1.95 dollars.

THE purpose of the series of paperbacks of which *The Structure of Atoms* is a member is to give first-year students of science a glimpse of the crucial discoveries through the eyes of the discoverers. In this book passages from original papers are set in a narrative which describes the development of the essential ideas in our modern picture of the atom, presenting each discovery against the background of contemporary ideas and knowledge.

The present work achieves its purpose very satisfactorily. It takes the reader through the evidence for the existence of atoms from chemistry and from the physics of gaseous discharges (quoting from Dalton, Avogadro and J. J. Thomson). A reasonably full account is given of the discovery of radioactivity and isotopes (quotations from, *inter alia*, Becquerel, the Curies, A. S. Russel, F. Soddy and H. G. J. Moseley) and of the nuclear atom (Rutherford). The final chapter deals with the extra-nuclear structure (Bohr). For a short book the coverage is full, though one wished that Marie Curie's recognition that radioactivity is an atomic phenomenon had been discussed explicitly and not merely mentioned incidentally.

This book provides an opportunity to glance at some of the most important publications of the modern age for students who might not otherwise be able to read them. It should also interest those whose primary studies are in fields other than science. [The late] K. E. B. JAY

## INTERACTION OF TECHNOLOGIES

AWARDS BY THE SHELL CHEMICAL CO., LTD., AND THE BRITISH ASSOCIATION FOR THE  
ADVANCEMENT OF SCIENCE

THE results have recently been announced of the world-wide award being sponsored jointly by Shell Chemical Co., Ltd., and the British Association for the Advancement of Science on the theme of "The Interaction of Technologies". The judges have decided that the main prizes should be shared between the authors of two papers, of equal merit—Mr. J. W. S. Hearle and Mr. L. W. Boxer—and they have both received a prize of 150 guineas.

Among the members of the panel of judges were Sir Robert Robinson, F.R.S., Mr. G. B. R. Feilden, F.R.S., Dr. D. O. Martin, O.B.E., and Mr. L. J. F. Brimble (editor of *Nature*).

The prizewinning papers were read at the recent British Association meeting at Cambridge.

The Award is being offered annually for seven years and the terms of reference for the 1965 Award were as follows: "It is acknowledged that there are divisions and barriers between different technologies at the moment and it is agreed that these impede scientific and industrial progress. We believe that there is more common ground between these existing technologies than is normally conceded".

The first of the prize-winning papers follows. The second will be published in the next issue of *Nature*.

## INTERACTION OF TECHNOLOGIES

By L. W. BOXER

Counsellor and Head of the Technical and Economics Division, European Nuclear Energy Agency, Organization for Economic Co-operation and Development, Paris

THE conjunction of a rapidly increasing interest in the role of science and technology in modern society, and the relative multiplicity of practitioners in the field to-day compared with only 40–50 years ago, means that it is becoming increasingly difficult to say anything new when attempting to explore a topic as complex as the interaction of technologies. Notwithstanding this dearth of originality, I feel compelled at the outset to restate the basic tenet—however trite—that the eternal riddle of the relationship between the forces within Nature and the forces within man has never been more pertinent in the history of human civilization than to-day, when we find ourselves precariously balanced at the fulcrum between man-manipulated natural forces of immensely constructive and destructive potential.

It is also general knowledge that, until recent times, discoveries of the nature of our environment and the evolution of scientific thinking had had relatively little impact on the organization of society, and that changes which resulted in human attitudes were confined to minority groups consisting chiefly of natural philosophers and theologians. With the advent of the industrial revolution, the expansion of manufacture and trade—stimulated by frequent wars—the situation changed rapidly in those countries whose political institutions and whose resources in manpower and materials were in a balanced relationship for such development.

These facts have long been recognized and need only to be repeated to emphasize the fact that we are already beyond the turning point from when man's growing knowledge of the eternal forces of Nature were still in step with his capacity to relate the implications of such knowledge to his contemporary needs. To-day it is generally conceded that the two factors are very much out of step and that the individual—whether scientist or layman—is beginning to experience a growing sense of personal impotence in adapting to the avalanche of scientific and technical knowledge, and a growing concern over the great tracts of isolation which appear to exist between areas of intellectual activity.

Unfortunately the fragmentation of scientific thought and activity cannot be conceived in such a way that the situation presents itself as a rough jig-saw puzzle, where it is only necessary to relate the boundaries of the fragments to each other in order to perceive the correspondence

between their profiles. Obviously, discoveries are yet to be made, and these may alter the intellectual shape of many areas of scientific investigation, and reveal fundamental links which were previously unsuspected, as was the case in the relationship between physics and chemistry in the nineteenth century, and as is now the case with chemistry and biology. The lack of such links, however, constitutes a series of gaps in knowledge rather than barriers or divisions between branches of knowledge and practice, and there is evidence that the barriers which have become insinuated between various branches of scientific activity have their origin in human weakness rather than in the incompleteness of human knowledge of the natural order.

Even a cursory examination of the history of science and natural philosophy will immediately reveal the falsity of denying the principle of common ground between all branches of science and their application in the technologies. It becomes immediately evident that only in recent times has the growing body of scientific discovery and application made it increasingly difficult and finally impossible for any single individual to practise science to the full extent of contemporary knowledge, as was feasible for his historical predecessors. Compartmentalism then appears in its true perspective as a purely arbitrary expedient to enable groups of individuals to concentrate in depth on a programme of education and application in a particular branch of science. However necessary it may be in the interests of progress to pursue a particular investigation in depth, it is tediously necessary to bear in mind the old maxims that a horizon is invisible from the bottom of a mine shaft, and that scientific knowledge and truth are the eternal parents of all technological offspring. Just as it may seem incongruous to project barriers between the technologies, it would be equally incongruous to examine a family illness without examining not only the interrelationships of the children, but also their joint relationship with the parents. This leads me inevitably to the conclusion that in any examination of the interaction of technologies, a good deal of attention should be given to the interaction of technologists, both within the scientific community and with society in general. It might, therefore, be more profitable to place particular emphasis on the complex humanistic elements of the contemporary situation, rather than to

attempt to repeat the common scientific principles which underlie all technological activity, and to arrive at purely abstract conclusions.

But before doing so it would be relevant to direct attention to a particularly prominent example of failure of one technology to interact with others. It is astonishing to observe the comparative isolation of the knowledge gained in the workings of the conscious mind and of the revelations of man's role as a rational being, in other words, of his capacity for objective evaluation of the relative significance of applying scientific thought and discovery in a developing society. A second example is the lack of cohesion between the current situation in science and technology, and knowledge and experience gained in recent years of the forces which control and influence the development of society. So to begin with, there are two technologies which have so far been largely missed out of the interaction altogether, namely psychology and sociology, and which could otherwise provide us with some insight to self-knowledge and the behaviour of human beings in their social environment. This is a significant oversight in a period in which there are frequent professions of awareness of the narrowness of mind and prejudice engendered in us by our educational and social background. Is it not likely, then, that man is frequently attempting to exercise highly skilled judgment of mind over matter without a fuller understanding of the mechanism of the mastery of mind over mind? If, then, it may be postulated that the present impression of discontinuity within the scientific and technical community is a purely behavioural phenomenon, then it may be relevant to attempt an appraisal of the current thinking habits acquired by scientists and technologists as a fundamental factor in this enquiry.

It is facile to repeat that the instinctive human regard for the preservation of the intellectual and material interests of the individual is the root cause of the formation of autonomous clans within the scientific and technical community, which are uniquely absorbed in the importance of their own affairs, and interested in their relationship with other clans primarily with the view of maintaining the preservation of relative status. This platitude misses the point, first, that for practical reasons arising from human limitations recent advances have made it essential to provide autonomy in different branches of science in order to achieve a desirable degree of organizational efficiency, and secondly, that practically all professional groups to-day are faced with overwhelming difficulties in communication not only between other specialized groups but also within their own speciality. There is the perpetual problem of determining the optimum proportion of total working time which can and should be devoted to keeping up to date, even within a limited field, and the way in which such time can be spent to the best advantage. A great deal of discrimination is now needed to discern the personal usefulness and relevance of the enormous amount of material which is now available through the media of publications and organized meetings. Some progress is being made on the physical problems of information retrieval and information transfer; but is factual knowledge in itself enough without an individual readiness to see oneself as an integrated, rather than an isolated, entity within the scope of human learning? If it were possible to sum up the inestimable number of gaps in knowledge and understanding between individual people with a similar tradition of scientific training and discipline, the total might even surpass in magnitude the much-publicized single gap between science and the humanities—which have recently been presented as the 'two cultures'—and where again the recognition of the inherent problems does not seem to have progressed beyond general expressions of awareness, to the accompaniment of a good deal of unconstructive argument.

The very terms 'science' and 'the humanities' in themselves are a typical demonstration of human wilfulness

in creating distinctions in fields of learning. 'Science' has been adopted as a convenient term for grouping the manifold studies of animate and inert matter, and the forces which influence its behaviour; and 'the humanities' has become an equally convenient term for grouping the branches of study of human activities. But is it not beyond the bounds of human capability to assert that these two arbitrary concepts are entirely unrelated and can never become integrated within a continuous intellectual perception of reality? It is inevitable, therefore, that the barriers created by our present basic thinking habits should be reflected in a certain lack of communication between many of our institutions. Indeed, contemporary psychological attitudes among many practitioners of science and technology probably present the most formidable problem in the effort towards achieving greater unity in these fields. We have to reaffirm to ourselves that science and technology must be maintained as branches of learning, and must not deteriorate into becoming attitudes of mind.

Perhaps the most obvious topical issue is the rigid distinction between scientists and engineers or technologists, which is aggravated to some extent by the unfortunate connotation of scientific activity into the categories of 'pure' and 'applied', from which the inference is often drawn that exercise in the abstract field is an intellectually clean occupation as opposed to a supposed vulgarity associated with activity in the material field, particularly where commercial considerations are important. The root of this distinction can probably be traced back to more than 150 years ago when craft technique first began to be used on an industrial scale in advance of the direct application of science, so that technology originally became established in industry as practical craftsmanship with very little tradition for intellectual training. The scientific approach was most likely regarded with some suspicion, and was only adopted to the extent that it was able to produce a practical and profitable result.

It is understandable that, in such circumstances, scientists would feel that the aims of industry would have little real connexion with the aims of science, and that industry would in fact tend only to impose restrictions on scientific intellectual liberty. Times have changed, however, and with the enormous growth of competitive industry, the evolution of skilled industrial workmen from artisans and craftsmen to engineering scientists and technologists has been every bit as rapid as the evolution in scientific knowledge. Furthermore, the training of engineers in the technological applications of science has become just as rigorous as that of scientists, who can now no longer claim a monopoly over objective and creative thinking, nor justify an attitude of condescension towards the more pragmatic aspects of their art.

Nevertheless, as we all know, the academic isolation of the scientist from the engineer, however unrealistic and harmful to human development, still persists in 1965 and is actually fostered by a cult of snobbery which is as equally indefensible as the isolationism itself, and which it would be hypocritical to ignore. The outdated images of white coat and greasy overalls, intellectual and non-intellectual, are still unconsciously or even consciously preserved, prompted perhaps by a pseudo-aristocratic and anachronistic attitude towards the 'anathema' of the industrial revolution. Social distinctions between scientists and technologists in 1965 are just as artificial, as any such distinctions have always been between composers and musicians, playwrights and actors, sculptors, painters and architects or in any field which requires a duality of origination and interpretation for its expression. The one is the essential complement of the other and there is no foundation whatsoever for any kind of distinction which attempts to compare two different kinds of mentality of equal quality, but trained in different orientations. In spite of the diffidence which still surrounds the mention of the whole delicate question of class relations in Britain,

the social image of applied science could well be a significant factor in explaining why so many engineering places are now going begging in such British universities as provide them.

In effect, then, the professional engineer in modern society is still classified by many as being associated with craft industry with a non-scientific tradition, and indeed he still shares the generic title 'engineer' with to-day's skilled or semi-skilled workman who has not sought the rigorous educational training and intellectual discipline necessary to achieve professional competence. The situation is now further complicated by the introduction of a new category of specialists, the 'technicians', whose function and formation lie somewhere between that of the two arbitrarily defined 'engineers', although there is no reason for supposing that their relations with professional engineers cannot be modelled on those developed between fully qualified specialists and their technical assistants in other professions, as, for example, in medicine. In Britain, recognition in terms of a more prestigious title such as 'chartered engineer', and more enlightened teaching to place the functions of the professional engineer in perspective with those of people of lesser skill and training but who are nevertheless free to borrow the same generic title, may help to raise the status of the engineering scientist in the public mind. The recent decision to grant fellowships of the Royal Society to more engineers and applied scientists generally is a welcome recognition of overall contributions of technology to the advancement of science. Nevertheless, the social nuance still continues to be an insidious element in the pseudo-intellectual flux of forces which tend to isolate scientists and engineers from each other.

The seriousness of all the psychological obstacles which block incentive towards free communication should not be underestimated in any attempt to reconcile the two camps of abstract and practical activities. How then will it be possible for both sides to arrive at a mutual understanding, at the individual level, of the problems encountered in these two basic forms of scientific activity, and to gain an appreciation of the nature of the creative thinking which has to be applied in order to make their particular contributions to progress? There is, of course, excellent scope for improvement in interdisciplinary relations in many large research establishments where closely co-ordinated teamwork between scientists and engineers is essential for the development of the sophisticated experimental techniques which are vital to success in certain fields of advanced research, notably in the structure of matter and in radio astronomy. Furthermore, the rapidly increasing use of computers is likely to make an important contribution to fundamental investigations in cybernetics, as well as liberating the whole scientific and technical community from a multitude of time-consuming mental chores, and providing more scope for initiative and for inventive thinking.

It is perhaps through such media that the best conditions are created for a balanced interaction between science and various branches of technology, always provided that organizational structure is also geared to this objective, and that management is sufficiently enlightened to appreciate the importance of encouraging a balanced relationship between science and engineering in achieving a high quality of contribution to further knowledge. However, situations in which people of different specialist training are able to work together in a healthy jumble of practices are still rare, and the vast majority of scientists and engineers are destined to spend most of their working lives in the relative isolation of laboratories, universities, design offices, production sites, etc.

Here the problem is again basically one of the practical means of communication, but like most men dedicated to a profession, the first concern of scientists and engineers will be to do a specific job to the best of their ability. It would be unfair and unrealistic to expect people with

primarily sectarian interests to take the initiative in establishing the necessarily complex means of communication and in formulating the broad lines of policy designed for a general rapprochement in the different sectors of the scientific and technical community. Surely the responsibility here lies with management, which is uniquely placed to take the horizontal view, and which is becoming of increasing importance with the present high degree of organization in science and in science-based industries, particularly with the general tendency away from individual research and development effort to co-ordinated teamwork.

Nevertheless, managers themselves are not always exempt from the sin of narrowness of interest, although awareness is half the battle—the most comfortable half. The already growing interest in the relatively new science of management is an encouraging sign, as supplementary training of this kind is bound to enlarge the field of interest and sympathy between individuals charged with different fields of responsibility, and may help also to achieve a more rational distribution of skills and aptitudes.

In spite of the financial and practical difficulties, the principle of 'sabbatical' leave might be applied more generously and more generally to encourage individual incentive and capacity to go on learning, and to promote a general realization of the need for education to be a continuing process throughout the life of the individual. The inconvenience and temporary loss of manpower would surely be more than compensated by the general stimulus which would result from the successful coaxing of management into a professional approach to its responsibilities, and the possibility for specialists at all executive levels to bring themselves up to date in their own fields, and to realize where current advancements in knowledge have produced scientific and technological 'fall-out' in allied fields of activity. The value of this kind of movement of personnel between industry, universities and research establishments has already been demonstrated on a modest scale, and there is now not only a justification but an urgent need to enlarge the practice both within and between national boundaries.

Furthermore, the successes of CERN in the field of fundamental research in the structure of matter, of ENEA, Euratom and the IAEA in nuclear science and technology, of ESRO and ELDO in space research and engineering, and of the FAO and WHO in the support and conservation of human life have all demonstrated the scientific and technical as well as the political value of international co-operation, and such organizations deserve every future encouragement as a means towards the objective of greater unity in science.

Nevertheless, both national survival and the stimulus for technical advancement depend on competitive trading, and it is therefore inevitable that commercial secrecy should present certain obstacles to a free flow of information in industrial circles. It would be quite impossible to quantify the resultant losses represented by patents, secret design information and closely guarded manufacturing techniques in terms of impediments to scientific and industrial progress, or of the inefficiency engendered under the cloak of such commercial secrecy. This will only become apparent in retrospect when each sector of industry has been able to determine what is to be gained by less restrictive policies on the flow of knowledge and information, and whereas industrial federations have done much to promote co-operative progress, the further encouragement to share industrial skills and resources must rely on Government initiative.

In this respect, and in view of the significance of expenditure on a national scale in the overall pattern of the alliance between scientific and technological development, Government can play an important part in sponsoring the closest contact between national scientific research programmes and industrial development work. However, the achievement of good relations between the public and

private sectors is often adversely influenced as a result of a Government's own commercial activities in certain scientific and technical fields.

It is an unfortunate fact that in the public mind, and particularly since the advent of nuclear energy, the men and women in the ranks of scientific and technical community still tend to be regarded as something apart from the run of ordinary mortals, even though as individuals they share the disadvantages of being at the mercy of their personal prejudices and quirks of temperament as all human beings. Nevertheless, the dispassionate objectivity of the scientific outlook, and the readiness—in the face of undeniable evidence—to admit the possibility of being wrong, rouses strong (even if inarticulate) emotions of hostility among those who are devoted to the perpetuation of fantasy, and who respond by equating science with inhumanity. There is ample evidence that the scientific community is becoming increasingly conscious of its responsibilities to society and is willing to meet those responsibilities in terms of twentieth-century reality. Many scientists and engineers have also come to realize that the source of ideas has become of secondary importance to the influence behind the expression of ideas, and they are now more prepared to compete for positions in which their professional activities are subordinated to their political functions.

A great deal still remains to be done to improve the public image of science and to remove public suspicion of the morality of scientific pursuit, and there is still scope for further exploitation of all the powerful media now at our disposal to stimulate frequent and persistent public argument and informed discussion of the issues affecting the relationship of scientists and engineers with each other, and with society at large, including dispassionate analysis of the human motivations which impede improvements in relations.

So much for short-term solutions in counteracting the consequences of our self-created problems. There is still one fundamentally important factor in the evolution of thinking habits which, in the longer term, presents a much greater problem in the development of science and technology, namely, education. There is no doubt that nowadays many young people in the later stages of their basic education, when faced with the seemingly irrevocable choice of a life vocation, are still puzzling over the fundamental problem as to whether education is the key to a way of life or the means of earning a livelihood. Students and the public in general are continually being reminded of an apparently insatiable demand for more and more scientists and technologists, to continue the economic growth rates which have become the principal objective of all Governments.

On the other hand, relatively little is known either about the degree of efficiency with which the specialized training of scientific and technical personnel is already employed in a great diversity of organizational structures, or to what extent such specialized training is essential prior to a specific professional activity. But when, in spite of possibly unfavourable social prospects, and faced with the exigencies of getting a job, the would-be scientist or engineer poses his candidature without having been equipped to view the whole scope of science in broad perspective, he is so overwhelmed by the potential breadth of his studies, and by the vast accumulation of knowledge to be acquired in depth, that not unnaturally he seeks refuge in the specialization for which he has shown the greatest aptitude under the restricted conditions of his earlier formation, to the everlasting detriment of his future capacity to appreciate the problems in other fields of learning. We have arrived, then, at the paradoxical situation where collectively man knows more now about himself and his environment than ever before in history, but is incapable of providing himself individually with more than a fragmented appraisal of this accumulated knowledge, before plunging into the relative mental

security of a particular pattern of specialist thinking (always assuming that he still chooses to go on thinking at all).

Recent history shows us that educational reform has been a continuous process throughout more than a century and at a rate which has been more or less in correspondence with social and economic evolution. However, to-day our experience of the rapid changes in civilized society in the past few decades, and our consequent ability to forecast the trends of the future, should provide us with an unprecedented opportunity to anticipate the kind of educational pattern which will be needed in the future, and the nature of the reforms which must therefore be put in hand to-day. Once again, fundamental rethinking is required, beginning with a thoroughly objective reappraisal of the relevance of the present content of education and teaching methods to the needs of modern society, and a critical analysis of the basic criteria in education which should be afforded to everyone, even though this might involve the relegation of some sacred pillars of learning which have masqueraded for years under the guise of logic and memory training media.

The disruption caused by radical changes need not be enormous and could be introduced in such a way as to take due account of the inertia of the present educational machinery. A golden opportunity now exists in Britain, where the ground has already been broken by the establishment of the comprehensive schools. Governmental initiative would, of course, be vital and could take the sponsorship of experiments in a number of provincial centres in which a specially designed course of secondary education would be dovetailed into a special degree course at selected institutes of further education. The aim should be to direct secondary and tertiary studies away from a strict subdivision into relatively isolated subjects, and to place particular emphasis on the evolution of ideas over the history of civilization, and an understanding of the factors which controlled their success in their contemporary settings. Detailed and lively instruction in the history of natural philosophy and religion, and their relation to the evolution of scientific thought would place the concept of entirely separate cultures in a perspective of total irrelevance to a unified concept of cultural activity. The development of mathematical philosophy, technique and application (including ultimately the elements of logic as embodied in computer theory) would then fit into these studies as part of a natural sequence. The special secondary course should also include English and at least one other modern language (taught by the most up-to-date language laboratory techniques) with particular emphasis on those aspects of language which limit the communication of ideas between people of different nationalities. Furthermore, the importance of self-knowledge and the awareness of human physical and intellectual limitations could be revealed to some extent by a study of the fundamentals of physiology and psychology. An equally essential tributary to this main stream of thought would be a study of historical influences on art, music and literature, and in order to gain some insight into the problems of modern Western society, the elements of economics should complete the list.

Such a special secondary course should perhaps give first priority to the philosophical treatment of the whole range of the syllabus, technological aspects being introduced as consequential and sequential, and left for further development in the tertiary course which would make provision for the study of one or two subjects in depth in addition to the continuation of the broad basic programme previously outlined. Each student would thus have an opportunity of creating a personal concept of the full scope of the intelligence of civilized man over the centuries, which is essential for a balanced view of the contemporary scene and for the difficult task of choosing the subsequent emphases in one's personal further education. Such a programme will seem over-ambitious and hopelessly

impractical if judged by present concepts of what is vital and what is useful for an educated person to know. Even if an optimum solution could be found, it is fairly inevitable that the completion of some kind of specialized study course and the resultant feed-back of the individual's educational background into society would add one or two years to the present time-scale of formal education. But given the resources, is this such a great sacrifice in the long term in order to achieve a society which has a greater consciousness of its scope, together with a balanced perspective of specialist activity and its contribution to human progress?

The idea is far from being new. Plato is quoted as saying the following in his famous *Republic* about the

students of his equally famous Academy: "They will be offered all at one time the sciences which they have studied at random in their adolescence, so that they can get a broader view of the relationships between these sciences and by this means become acquainted with the true nature of reality".

In the fourth century B.C. it was, of course, possible to read the output of practically all the contemporary thinkers—a task which is beyond human capability to-day. Nevertheless, it would be ironic if, more than twenty-three centuries later, man has become so overwhelmed by the revelations of his own intellectual industry that he finally becomes the slave, rather than the master, of knowledge.

## THE NATIONAL PHYSICAL LABORATORY, TEDDINGTON, MIDDLESEX

ON April 1, 1965, the National Physical Laboratory, together with most of the other stations of the former Department of Scientific and Industrial Research, became part of the new Ministry of Technology, and on the same day the National Chemical and National Physical Laboratories were amalgamated under one director. This year, therefore, for the first time, it was the combined Laboratories that were open for inspection during open days which were held on May 19–21, when 330 items were on display. Some 3,570 visitors attended during the first two days, while on the final day visits were made by more than 1,200 sixth-form pupils from 62 schools. No lectures were arranged, but two films were shown: one, *Ship Shape*, dealt with the work of Ship Division, and the other, *Precise Measurement in Engineering*, with the metrological work of Standards Division.

It is convenient to consider the various Divisions of the Laboratory as constituting a number of groups, each group having common interests. Thus there are two Divisions—Aerodynamics and Ship—concerned essentially with the movement of a solid body through gaseous or liquid media. Four others—Applied Physics, Chemical Standards, Light, and Standards—are interested in accurate measurement and standardization. Autonomics and Mathematics devote much of their effort to automation and computers, while Basic Physics and Metallurgy are concerned with the investigation of materials. The common interests between groups of Divisions were apparent from the items on display during the open days.

In Aerodynamics Division, research has been in progress for several years on base flows. This type of flow occurs behind wings or bodies, moving through the air, which are not shaped so as to converge to a sharp edge at the rear but are truncated earlier, leaving a bluff rearward-facing area or 'base'. Similar flows exist behind downstream-facing steps in a wall (the outer skin of an aircraft, for example) past which air is flowing. The problem is of considerable practical importance because the air pressure which acts on the rearward-facing area is usually low, making a contribution to the total drag of the aircraft or vehicle.

One of the Division's exhibits illustrated various methods which have been explored for reducing the drag arising in this way. One method at present being investigated consists of hollowing out the base, so that at the rear of the wing or body there is a thin-walled cavity with its opening facing downstream. The walls of the cavity are ventilated so as to allow air to bleed through into the cavity from the outer surface. This has the effect of alleviating the low pressures acting on the base. The preliminary results are encouraging, and further research on the method is in progress.

Two separate lines of research into methods of calculating the development of turbulent boundary layers are being pursued, with the ultimate objectives of improving estimates of the surface-friction drag of aircraft and ships, and predicting the undesirable phenomenon of separation of the flow from the surface. One method relies on an empirical correlation of nearly all existing data and should be more reliable than the more narrowly based existing methods; the second method uses the equation for the flow of turbulent kinetic energy to obtain a relation between the velocity and turbulent shear stress and their spatial derivatives, which is then solved simultaneously with the boundary-layer equation and the continuity equation on the KDF9 computer. This method requires a fairly small quantity of empirical information about the turbulence structure, which is being obtained as part of a wider experimental programme using a special wind tunnel. Experimental work is also being done on surface pressure fluctuations under turbulent boundary layers, which cause structural vibration, fatigue and noise.

The effort devoted to non-aeronautical aerodynamics is steadily increasing. One interesting investigation in this field concerns the collapse of cooling towers under wind loading conditions. This has been investigated using scale-models in the compressed air tunnel in which the increased air density raises the impact pressure of the airstream sufficiently to buckle specially prepared thin metal models (wall thickness 0.005–0.012 in.). Associated mathematical analyses have been made in the Mathematics Division. Work is also in progress on the aerodynamic stability of suspension bridges, with special reference to the Severn Bridge. Tall buildings, chimney-stacks and other tall, slender structures represent other examples where the natural wind can introduce loadings, particularly those of an oscillatory nature, for which no adequate provision is made in current *Standard Codes of Practice*. Wind-tunnel investigations have been undertaken to ensure that no unacceptable oscillations will occur on the General Post Office towers for London and Birmingham. Another interesting investigation, at present in progress, is that for the World Trade Center, a 1,350-ft. twin sky-scraper development for Manhattan, New York, which when built will be the world's tallest pair of buildings. On show also was a landscape model of a section of the Lancashire–Yorkshire motorway, on which wind-tunnel tests had been made in order to investigate the airflow with special reference to snow drifting in a deep cutting.

Another aspect of the problem of drag was illustrated by a hydroelastic model of a fully cavitating propeller in Ship Division.

The blade sections of fully cavitating propellers must have thin leading edges to avoid high cavitation drag with consequent loss of power and low efficiency. Despite the use of high-strength materials such as stainless steel, fully cavitating propellers with thin leading edges have failed structurally in service, and experiments are being made to determine the steady and unsteady stress levels in such propellers. Unsteady stresses occur mainly because a propeller has to operate in a non-uniform wake.

In order to predict full-scale steady-state stresses from a model propeller, the deformation under load of the model must be similar to that of the full-size screw. This condition may be closely simulated by making the model from a more flexible material; here this is an epoxy resin with a suitable filler added to adjust the elastic modulus to the required value.

The strains at selected positions on the blades are measured by means of very thin electrical strain-gauge rosettes attached to the blade surfaces. The energization of the strain-gauge bridges and the resulting output signals are controlled and measured from outside the tunnel by means of slip-rings and leads passing along the shaft into the propeller. Stress-levels in the blades are then calculated from these strain measurements.

The Division has recently also been investigating the potentialities of passive tank-type roll stabilizers to supplement the activated types at present commonly fitted to ships. Most encouraging results have been obtained. The passive ship roll stabilizer has certain advantages over the activated type. It requires no instrumentation, moving parts, or power supply, its action depending on the free motion of water from side to side in a rectangular tank.

The tank is incorporated in the ship structure as high as possible and usually extends from side to side using the maximum beam of the ship. The depth of water in the tank is such that at the resonant response frequency of the vessel the water moves from side to side with the same period of oscillation as the ship but lagging the ship motion by a 90° phase angle. The quantity of water transferred is such as to create large damping of the motion.

The design and development of the system are both simple and economic, and a scale model of the vessel to which it is to be fitted is used to prove the design. A demonstration of a typical installation in a ship model showed the principle of the stabilizer and the reduction in roll angles possible with such a system.

The Radiology Section of the Applied Physics Division which is concerned with the establishment of all types of standards in the field of radiation physics was able to exhibit this year the new 3-MV Van de Graaff positive ion accelerator. The acquisition of this machine considerably widens the range of the Section's activities. It will permit the establishment of standards of neutron flux density which are required for the calibration of neutron detectors and for the measurement of neutron reaction cross-sections. The machine accelerates beams of protons, deuterons or  $\alpha$ -particles which may be directed along one of three drift tubes to bombard targets of suitable material. One such drift tube leads to a target situated in a low scatter environment in which the source of neutrons is at least 20 ft. away from all walls, ceiling and floor, the essential equipment being supported on a light open-mesh grating (Fig. 1). By suitable choice of particle, bombarding energy, target material and angle of detection, monoenergetic neutrons can be obtained at many energies from a few keV up to 20 MeV. A second drift tube, leading to another area of the accelerator hall, will enable a beam of deuterons to be rapidly oscillated between two targets situated in a large graphite moderator. At a point midway between these targets a well-thermalized neutron flux of about  $10^7$  n/cm<sup>2</sup>/sec and having a very small gradient over a volume of about 100 cm<sup>3</sup> should be obtained. By this means it is hoped to estab-

lish a standard thermal neutron flux density standard which will be used to calibrate flux measuring foils; alternatively, a small beam of neutrons can be extracted from the moderator to calibrate neutron detectors for protection measurements.

Work in the Acoustics Section of the same Division lies largely in the field of psychoacoustics, and much interest was attracted by an exhibit showing the preliminary results from the latest in a series of subjective experiments designed to gain information on the relation between noise-levels and environmental factors on people's reactions to specific classes of noise, in this case aircraft noise. The tests were carried out at Farnborough during the SBAC Show in 1964. One object was to examine the validity of rating scale procedures for tests of this sort and to refine the techniques for subsequent use. One of the principal findings is that noisiness judgments depend not only on the noise-level received, but also on the listeners' inference about the noisiness at source. No significant difference was observed, however, between judgments of landing and take-off noise at corresponding sound-levels. The tests, for which 150 subjects took part, were spread over five afternoons. On the first afternoon the subjects were divided into four psychologically matched groups by means of their responses to 'annoyance' and 'semantic differential' questionnaires administered by the Applied Psychology Research Unit of the Medical Research Council. The aircraft noise tests occupied the remaining four afternoons during which the four groups were situated at indoor and outdoor locations variously sited with respect to the flight paths. The results accord closely with those of a smaller-scale experiment carried out at the time of the 1961 SBAC Show for the Wilson Committee on Noise, and their validity is now believed to be high as a result of the balanced-design cross-checks in the present series.

The new Chemical Standards Division, formerly the Division of Chemical Physics of the National Chemical Laboratory, illustrated work in chemical thermodynamics

Fig. 1. General view of the Radiology Laboratory, showing a drift tube leading to the open-mesh grating forming the low scatter environment

and molecular spectroscopy, the two main items on its programme.

Thermal properties (heat capacities, heats of transition, heats of fusion, triple points) of substances are required in the chemical industry for the development of the best production methods. Heat capacities of 12°–473° K are being measured to a high degree of accuracy by adiabatic calorimetry. The apparatus exhibited has been largely automated. In each of the four sets of equipment, the temperature of a shield isolating the calorimeter is automatically maintained within a few thousandths of a degree of that of the calorimeter. Heat inputs to the calorimeter are calculated from voltage observations recorded automatically on paper tape. Temperature increases are measured to a thousandth of a degree by means of platinum resistance thermometers and an automatic a.c. resistance bridge, readings of which are also recorded on tape. All the observations are processed by digital computer.

Values of Gibbs energies and heat contents of substances are needed by chemical engineers engaged in plant design; values can sometimes be obtained by measurement of equilibrium constants over a temperature-range. Apparatus used for the determination of equilibrium constants for the gas-phase hydrogenation of three ketones and an aldehyde was shown; the vaporized compounds, mixed with hydrogen, were passed over a catalyst held at a known constant temperature and the products analysed by gas chromatography. The results confirmed the values of certain thermally derived thermodynamic quantities and data inaccessible by other methods were secured, for example, a value for the entropy at 298° K of *s*-butyl alcohol, which could not be derived from low-temperature calorimetric studies because the alcohol did not crystallize.

Important information concerning the vibrations of some molecules can be obtained from the study of their absorption spectra in the infra-red and far-infra-red regions. Examples of the use of infra-red, far-infra-red and Raman spectra to obtain fundamental frequencies were shown. The results are used to calculate thermodynamic values, for example, the heat capacity of industrially important compounds. These calculations are complementary to measurements of the same quantities and permit extension of the results to a wider temperature range.

Two of the most interesting items on display in Light Division were a colour temperature meter and thin film components for the visible and ultra-violet.

A very simple and convenient colour temperature meter has been developed which can detect differences of 1° K between incandescent tungsten filament lamps. This instrument can be used in the National Physical Laboratory and similar laboratories to inter-compare standard lamps.

The colour difference detector is a sector disk with yellow and blue filters revolving in front of a photocell. With incident light at a certain colour temperature, the a.c. output from the cell will be zero; but any slight change of colour temperature will produce an a.c. signal which can easily be greatly amplified for detection on a meter. If, as is probable, the light is not at the 'matching' colour temperature, it may be made so by sliding across a coloured wedge. The displacement of the wedge required for a null signal is then a measure of the colour temperature of the light, provided that the spectral distribution is similar to that of a full radiator.

Extensions of this principle could produce an extremely simple and sensitive colorimeter which could be used in industry to detect deviations from colour specifications in goods such as textiles, and hence, possibly, to control the process automatically.

Work is proceeding on the development of a very efficient polarizing beam-splitter which consists of a glass cube split on a diagonal, the interface bearing an interference filter comprising many alternate thin layers of

magnesium fluoride and ceric oxide. This reflects only light of one direction of polarization, light of orthogonal polarization being transmitted. Samples made so far give an efficiency of separation of the two beams of more than 90 per cent.

Such beam-splitters find application in interferometry, where they can give efficiencies of four times those given by conventional beam splitters, and where the two beams being 'labelled' by their polarization can be manipulated separately without interference.

Thin film components for the vacuum ultra-violet are needed in space research, plasma physics and other spectroscopic applications. Most materials used in such components absorb strongly below 2000 Å, and work is in progress to determine the conditions necessary for efficient components.

Aluminium mirrors protected by thin layers of magnesium fluoride have given reflectivities of more than 80 per cent at 1216 Å, but deteriorate with time. It is hoped that further work will disclose the reason for this.

The application of lasers in the field of accurate measurement was illustrated by an exhibit in Standards Division.

For many years engineers' reference end bars have been measured accurately by means of wave-lengths of light, but such measurements have been limited to short bars by lack of complete purity in the colour of the light from the usual sources. The advent of separated isotopes, notably mercury-198 and krypton-86, permitted the production of purer radiations; but even then measurements could only be extended to 1 m with difficulty. The helium-neon laser, on the other hand, emits almost perfectly monochromatic light the wave-length of which has been measured at the National Physical Laboratory in terms of the krypton-86 radiation defining the metre. This practically removes the length limitation, and, in conjunction with other properties of laser radiation, extends the possibilities of measurement by light waves far beyond the usual measurement of end bars. A precise length-measuring machine using a laser has been designed and constructed using standard engineering techniques which will automatically measure the position errors of the lines on a scale with an accuracy in the region of 0.2 µm. Although there may be up to a thousand lines, their measurement takes only a few minutes; whereas by the classical methods a corresponding measurement used to occupy many hours. Moreover, the results are automatically recorded on paper tape and the subsequent analysis carried out by digital computer. Further developments will include application of the machine to metrological gratings and other types of scale, and refinement of its accuracy to better than 0.1 µm by closer control of ambient conditions.

Another exhibit which attracted attention in the same Division was an instrument designed for the easy and accurate measurement of distances up to one mile. This instrument known as *Mekometer II*, and believed to be the first of its kind in the world, can be regarded as a truly electronic tape-measure.

The device utilizes a light beam which is polarization-modulated in the ultra-high-frequency region. This measures the distance from the instrument to a reflector placed at the far end of the line. The modulation wave-length is conditioned by specially designed and constructed cavity resonators filled with dry air but allowed to acquire atmospheric temperature and pressure. By these means the velocity of light is excluded from the basic measuring equations and the results indicated by the device are scarcely affected by the state of the atmosphere. The accuracy is better than one part in one hundred thousand. Distance is indicated on dials directly in feet and the whole process takes but a few minutes whereas existing methods take hours. The first tests have been made using the National Physical Laboratory 800-m (984-ft.) base and the results obtained from *Mekometer II* differ from the true length by less than 0.005 ft. It is hoped to

improve the difference to  $\pm 0.002$  ft. later in the year. A commercial licence to manufacture has been granted.

Considerable attention is being given in Autonomics Division to the possibilities of the automation of industrial processes, and visitors to the Division were able to see an automated small-scale distillation column in operation. The column, designed to separate a mixture of ethanol and water, is now coupled to a Ferranti *Hermes* digital computer, and direct digital control of top product composition has been achieved. The equipment is being used to investigate techniques for estimating the dynamic characteristics of the process, and for achieving adaptive and optimal control. The computer accepts signals from temperature, flow-rate and product composition transducers. The last of these is a newly developed instrument based on the use of very-high-frequency resonators immersed in the liquid. Control is exercised by the computer over input heater power and reflux rate. Alterations can be made in the feed composition.

A steady-state model, based on the materials balance equations for the column, has been programmed in the computer to provide predictive control of the process to an optimum steady state. A dynamic model is derived in the computer by applying to the control variables small, specially designed binary perturbations. By cross-correlation of the resulting signals from the column transducers with respect to the applied perturbations the computer derives estimates of parameters describing the dynamic behaviour of the column. These estimates are continually updated to keep pace with temporal changes in the dynamic behaviour and they therefore define an adaptive model for use in more sophisticated control techniques. Programming for full adaptive control is well advanced and will include investigations of hill-climbing methods and of techniques based on dynamic programming.

Another problem being investigated in the Division is that of information retrieval. The retrieval of scientific information is now a formidable, but important, task. It presents many challenging problems which, with the possibility of mechanising many of the routine operations, are receiving much attention.

A mechanical system is being developed in which documents are indexed and enquiries are expressed in terms of descriptors. Each descriptor is a ground of associated key-words, the grouping being based on statistics of word co-occurrence in documents. During the retrieval process a comparison is made between the set of descriptors assigned to each document and the set used in formulating the request. Documents for which a perfect correspondence is found are retrieved, but it is also worth retrieving documents that have been assigned most, but not all, of the required descriptors. The retrieved items are therefore rank-ordered according to their degree of correspondence with the request.

The standard of retrieval which has already been achieved entirely by computer is illustrated by the following example. An enquiry for information on 'magnetostrictive band-pass filters' was made with reference to a collection of 12,000 abstracts covering electronics, computers and aspects of physics and geophysics pertinent to radio communication. The five abstracts which follow were at the top of the rank-ordered output:

(1) Electromechanical filters for use in telecommunication equipment. Includes descriptions of construction and performance of reed type magnetostrictive and piezoelectric filters.

(2) A practical electromechanical filter. Details of materials and fabrication techniques are given for narrow-band torsional filters.

(3) A theoretical analysis of the torsional electromechanical filters. The mechanical properties of a torsional system are expressed in terms of electrical equivalents. By introducing a transducer transfer ratio with the dimensions of charge a method is developed for the design of electromechanical filters based on equivalent electrical

networks. Pass band ripple spurious modes and transducer matching are discussed.

(4) Surface magnetostatic modes and surface spin waves. The general existence of surface wave modes in the frequency region above the spin wave band is shown.

(5) Image parameter theory for mechanical quadrupoles in compressional or torsional oscillation. The equivalence of the parameters of a mechanical system transmitting compressional or torsional oscillations and the parameters of an electrical transmission line is established. The design of mechanical filters is described and design formulae with response characteristics are given for the basic filter sections.

Much of the pioneer work in the design and application of computers was carried out in the Mathematics Division, which now has a *KDF9* in addition to its older machines *Ace* and *Deuce*. For many years the Division has concentrated on developing techniques and programmes for facilitating the scientific applications of computers. These have been used not only on the Division's own research in numerical analysis, applied mathematics, theoretical physics and engineering problems but also on work for the Laboratory as a whole and for outside organizations. The attention of visitors was directed to a variety of such studies. These included the calculation of stresses in concrete cooling towers, which was associated with experimental work on show in the Aerodynamics Division, and work on the mathematical design and analysis of ship hulls.

For any shape and size of cooling tower, the stresses induced by the wind and by the tower's own weight can be computed by solving a set of rather complicated differential equations. For routine office work, however, it is more convenient to refer to data sheets or graphs which summarize the results relating to suitable skeleton sets of shape parameters. The design of cooling tower shells for the Central Electricity Generating Board is now based entirely on data sheets derived from the method developed at the National Physical Laboratory.

The problem of mathematical ship fairing has been successfully treated; mathematical surfaces are fitted to the detailed measurements of a ship's hull taken from the naval architect's design drawings, and these can be used to simplify the construction of the ship. In addition, improved hull forms have been estimated following a statistical analysis of model tests which has produced an empirical relationship between resistance and suitably chosen geometrical parameters of the hull shape.

The work in Metallurgy Division on high-field superconductors, besides constituting a field of research, is an illustration of the part the National Physical Laboratory can and does play in undertaking from time to time the technical direction of national projects financed by Government.

The technological importance of superconductors has been recognized by the formation of a national Superconductivity Advisory Committee of which Dr. N. P. Allen, superintendent of the Metallurgy Division, is the chairman. This Committee is responsible for co-ordinating the research and development effort throughout the country formerly on behalf of the Department of Scientific and Industrial Research, and now of the Ministry of Technology.

The area in this field in which the Metallurgy Division is itself engaged is concerned with endeavouring to elucidate the relation between the metallurgical properties of superconductors and the ability of certain of these materials to sustain large current-densities in high magnetic fields. To this end, niobium has been selected for investigation since it exhibits the required behaviour in relatively low magnetic fields, thus making the necessary experiments somewhat simpler to perform.

The relation between the deformation of single crystals of niobium and their superconducting properties has

previously been investigated in the Division, and this work has now been extended to heavily deformed polycrystalline niobium. Cold-swaged niobium wire has been progressively annealed for fixed periods of time at temperatures of 200° C, 500° C, 700° C, 900° C and 1,100° C, and measurements of magnetization, critical current, and restoration of resistance taken from 4.2° K to 1.5° K after each heat treatment. A peak in the mechanical hardness for the 500° C treatment is matched by peaks in the various critical fields as defined by magnetic and resistance measurements, and it is believed that strain-ageing provides pinning centres which prevent the motion of magnetic flux through the material.

An additional piece of work involving the examination of the superconducting properties of sintered mixtures of copper and niobium was motivated by the present interest in adding large quantities of copper to superconducting wire to mitigate the effects of 'degradation' and 'flux jumping' when the wire is wound into coils. The properties of the resulting compacts are found to be strongly dependent on the distribution of the niobium particles in the sintered mixture, in addition to its density and composition.

Another interesting item on display in the Division was a goniometer stage adjustable over a wide range of angles, designed and built at the Laboratory for use in the *B.M.6* electron microscope, together with examples of the much increased information it has been possible to obtain as a result.

When a metal deforms at normal temperature the stress increases continuously with the amount of deformation. This is the phenomenon of work hardening. The enforced change of shape is accommodated by blocks of metal sliding over each other on certain preferred atomic planes (slip planes), a process facilitated by movement along these planes of a particular type of atomic defect known as a dislocation. During deformation the number of dislocations may increase from  $5 \times 10^7/\text{cm}^2$  to more than  $1 \times 10^{10}/\text{cm}^2$ , and as they move they interact with each other, tangling together to form an irregular cellular structure (Fig. 2). Moreover, the degree of strengthening

Fig. 2. The goniometer stage, adjustable over a wide range of angles, designed and built in the Laboratory

produced during deformation is known to be proportional to the square root of the number of dislocations present. It is therefore necessary to obtain as much detail as possible about the dislocation tangles so as to find out which types of dislocation are interacting with each other and why strength should be dependent on their number.

The technique for distinguishing between the dislocations makes use of a result obtained from electron diffraction theory, that a dislocation produces no contrast, that is, its image can be made to disappear, when electron diffraction conditions are such that the diffracted beam lies normal to the displacement field of the dislocation. This displacement field characterizes the type of dislocation; it is called its Burgers vector, and hence by knowing the diffraction conditions when a dislocation disappears its type can be determined.

Until now a bright field technique has been used in which the specimen is viewed in the usual manner using the directly transmitted beam. Under this condition, however, in order that the disappearance condition shall be unambiguous the diffraction conditions have to be arranged so that apart from the transmitted beam only one other diffracted beam operates. This is normally difficult to achieve.

A considerable improvement has now been made by the use of a high-resolution dark-field technique in which the specimen is viewed using a chosen diffracted beam instead of the transmitted beam. Two beam conditions are no longer essential though it is necessary to be able to tilt the electron beam so that the desired diffraction spot may be brought to the centre of the microscope. This has been achieved by the use of a rotatable beam tilt device. To vary the diffraction conditions it is also necessary to tilt the specimen inside the electron microscope so that it can be made to lie at a variety of angles with respect to the electron beam. Since the commercial specimen tilt device only permitted this within an angular range of  $\pm 5^\circ$ , the new goniometer was designed (Fig. 3). The specimen which is mounted between special grids, 2.3 mm in diameter, is placed in the hemispherical ball A which is tilted by the action of the three small push-rods housed in the cartridge B. The movement of the push rods is controlled by the swash plate C which is motor driven from outside the microscope. The specimen can also be rotated through  $360^\circ$  in its own plane by action of the worm and wheel D, so that, by a combination of rotation and tilt, the specimen can be accurately manipulated to lie in any plane within the angular range of  $\pm 30^\circ$  with respect to the electron beam. Some success has already been obtained with this goniometer in determining the

Fig. 2. A tangle of dislocations in iron ( $\times c. 10,000$ )

Burgers vectors of dislocations in iron and an iron alloy deformed over a range of temperatures.

At the open days last year, the Basic Physics Division released news of the discovery of a powerfully stimulated emission source in the sub-millimetre region at 0.34 mm wave-length. This year visitors were able to see the progress made in the development of this discovery into a practical laboratory source. The device is a gas discharge maser utilizing a rotational transition in the ON molecular radical, and has been given the name *Terairon* derived from the frequency of the radiation emitted. Discharge tubes only 3 ft. in length give useful amounts of power, and a commercial model with a portable power-pack is now being developed in co-operation with an industrial organization. Although the device is still at an early stage of development it is believed that great value is to be derived from making a powerful sub-millimetre source commercially available as soon as possible. At the Laboratory, the *Terairon* has already been used to measure errors in the lead screw of a lathe, and for dielectric measurements. The source promises also to be of value in teaching institutions because the wave-length is particularly suitable for demonstrating interference and diffraction phenomena.

A new field of research—Non-linear Optics—has recently been opened up in Basic Physics Division, and one of the items on display showed the results so far. The basic objective is to devise a modulator which will mix together optical and microwave signals in such a way that the output is a monochromatic signal the frequency of which equals the sum of the frequencies of the two incident waves. This follows work at low frequencies by Bührer, Baird and Conwell<sup>1</sup>. Present experiments are aimed at producing an efficient mixer in which the microwave energy is used to the best advantage. The system uses a tunable resonant cavity in which a circularly polarized 10 Gc/s microwave field is set up, and it is expected to

obtain complete frequency conversion with a microwave input of 10 W or less.

The High Temperature Group in Basic Physics Division is concerned with the behaviour of elements and compounds at elevated temperatures. Species, different in composition from those which exist at normal temperatures, often exist under these conditions and may be condensed to form new materials at normal temperatures. Gaseous reactants may be heated to 5,000°–20,000° K in the familiar d.c. discharge and radio frequency induction plasma torches which were exhibited. The RF plasma torch was used to demonstrate the oxidation of a mixture of metal halide vapours in oxygen plasma to form mixed oxides of small particle size and controlled stoichiometry. These devices are unsuitable, however, for reactions in which solid feed materials must be used since heat transfer from plasma generated in these ways is generally only sufficient to melt the particles.

A rotating plasma furnace was also exhibited in which the plasma of a d.c. arc column is expanded by tangential bombardment from cool gas molecules to occupy a volume of approximately 2.5 l. Solid feed materials may be vaporized in this device. Although arc expansion by this principle has been demonstrated before with low-current (~10 amp) discharges, the device exhibited is the first to include an electrode configuration by which high-current (~400 amp) expanded discharges may be stabilized at atmospheric pressure for long periods of time. The power (~20 kW) dissipated in this device and the residence time of particles fed into the plasma are great enough to enable solid feed materials to be vaporized completely. It is intended to use this furnace in fundamental studies of vaporization in plasmas and for a variety of chemical syntheses which involve high-temperature species.

## OBITUARIES

### Prof. Wilson Smith, F.R.S.

PROF. WILSON SMITH, emeritus professor of bacteriology in the University of London, died on July 10 at the age of sixty-eight. Wilson Smith's life-work in bacteriology may be considered as in three succeeding phases. His reputation was built on his early research, when he was a full-time worker under the Medical Research Council. Later, though by no means giving up his own investigations, he became an excellent teacher; and he finally devoted more and more time, as an elder statesman, to help in guiding scientific policy.

He was born on June 21, 1897, in Great Harwood, Lancashire, and always remained something of a Lancashire man. He went to school there at Accrington Grammar School and served with the 107th Field Ambulance during the First World War from 1915 until 1919. He then entered as a medical student at the University of Manchester, qualifying in 1923.

After a short while in general practice, he felt the call of bacteriology and took the course for the diploma in bacteriology at Manchester under Prof. Topley. He not only obtained the diploma but also married one of Topley's young demonstrators. He then came to London, joining the staff at the National Institute for Medical Research, then at Hampstead.

Those were days when filter-passing viruses, as we then called them, were first becoming a subject of serious study. Wilson Smith took part in the exciting developments in this field, working at first under S. R. Douglas on vaccinia virus. Then, in 1933, came his most important contribution to knowledge. He and I were making an all-out endeavour to find a virus in influenza: even as we planned,

I fell sick with the disease and Smith carried on, inoculating my filtered throat washings into various laboratory animals. Guinea-pigs, rabbits and mice were injected, mostly intramuscularly or subcutaneously; and nothing happened. Then came the turn of ferrets, available because of their use by Laidlaw and Dunkin in current work on distemper. Somehow inspired, he this time put some of the washings up the ferrets' noses and two days later one developed nasal discharge and sneezing. This first step led on to an immense amount of work on the 'flu virus and subsequent developments kept him interested for the rest of his life. Discovery of the susceptibility of ferrets to 'flu entailed the building of a 'ferret hospital' with 32 isolation units at Mill Hill. Laidlaw, Smith and I made daily clinical rounds of our ferret 'patients' every morning for some years, working in the laboratory at Mill Hill in the morning and returning to the Institute at Hampstead for other work in the afternoons. It was duly revealed that mice as well as ferrets could be infected, that neutralizing and complement-fixing antibodies developed in the sera of both man and ferret, that our virus was related to that of Shope's swine influenza virus and that a formalin-inactivated vaccine could be used to immunize. All this came out of the team-work: particular contributions made by Wilson Smith himself were to show that the virus would grow in fertile hens' eggs and in tissue culture.

In 1939 Wilson Smith left Mill Hill to fill the chair of bacteriology in the University of Sheffield. With the outbreak of the Second World War it was a difficult time to begin a new kind of life. Besides his teaching duties, he was put in charge of local public-health bacteriology

and of the penicillin treatment of local Service casualties. He had the unpleasant experience of having his house collapse on top of him as a result of an air-raid; fortunately he was in a cellar and was unharmed.

Soon after the War, in 1946, Wilson Smith returned to London to the chair of bacteriology at University College Hospital Medical School, where he remained until his retirement in 1960. At University College Hospital he stimulated much further work, particularly on influenza and poliomyelitis. He showed that some host components became integrated into the structure of influenza virus particles, but his conclusion that this incorporation is of basic importance in virus evolution is somewhat doubtful. Wilson Smith's reputation as a teacher and investigator rests mainly on his clarity of thought and utterance, his critical faculty and his very high standards of accuracy.

These qualities proved invaluable in his later years when he came to be much in demand as a member or chairman of numerous committees of the Medical Research Council and other bodies. He was a member of, the Medical Research Council from 1961 until his death. Several of these committees were concerned with virus vaccines—for influenza, poliomyelitis and measles. Sir Harold Himsworth has written of Smith: "The development of the safe and effective vaccines now available in this country is in no small measure due to his own efforts".

On his retirement he became consultant adviser to the Microbiological Research Establishment at Porton. While here he edited a book on *Mechanisms of Virus Infection*, of which he wrote the introductory chapter himself.

Wilson Smith was elected a Fellow of the Royal Society in 1949 and delivered its Leeuwenhoek Lecture in 1957. He became a Fellow of the Royal College of Physicians in 1959. The University of London gave him a Graham Gold Medal in 1960. His very high standards contributed greatly, through his own work and that of those whom he taught, to the advance of virology in its rapidly developing years. At the end, when he developed a progressive and debilitating disease, he showed great courage in extracting the last ounce of energy from himself in the service of medicine. Though his enthusiasms had their ups and downs, he had a keen sense of humour. He was an enthusiastic violin player and derived much enjoyment, and some profit, from buying and selling old violins.

He leaves a wife and two married daughters.

C. H. ANDREWS

Prof. B. Lindblad

BERTIL LINDBLAD was born on November 26, 1895, at Örebro, Sweden. After studying at the University of Uppsala, and later becoming an assistant at the Observa-

tory there, he joined the Stockholm Observatory. He became director of the Observatory in 1927 and held this office at the time of his death.

Lindblad was an important pioneer in the determination of absolute magnitude from studies of stellar spectra and also in the development of the kinematics and dynamics of our own Galaxy. Following on the work of Adams and Kohlschutter, who demonstrated that the difference between giants and dwarfs could be seen in stellar spectra, Lindblad showed that the cyanogen bands were an important criterion of absolute magnitude. He derived absolute magnitudes from his own scheme of spectral classification, and used these absolute magnitudes, combined with the available apparent magnitudes and proper motions, to give distances and transverse velocities. He was able to show by means of these data that the motions were consistent with his concept of the Galaxy as an assemblage of rotating sub-systems, the rotation and dispersion of the internal velocities varying with the degree of flattening of the sub-systems. He considered the high-velocity stars as forming one of these sub-systems, and explained the tendency of the directions and motions of these stars to avoid the hemisphere, the centre of which is in the galactic plane at longitude 60°—in modern terms, to avoid the direction in which the Galaxy rotates. Lindblad demonstrated that the phenomenon of star streaming was connected with galactic rotation, and that the direction of the preferential stream was approximately the centre of the galactic centre. Lindblad is therefore an important figure in the development of stellar dynamics from the early work of Schwarzschild and Eddington to the later work of Oort, in which the notion of galactic rotation is fully recognised in galactic kinematics. He later extended his interests to the dynamics of galaxies in general, and wrote many papers about the development of spiral galaxies.

While Lindblad's work on stellar luminosities was very practical in character, and consisted of determining luminosities from the cyanogen band and from an extended scheme of spectral classification which he himself developed, his work on galactic rotation and his researches on spiral structure were extremely mathematical, and in many topics which are of interest to-day in connexion with theories of the Galaxy it will be found that the leading ideas are contained in Lindblad's work.

His influence over Swedish astronomy and Swedish astronomers was very great and he was extremely well known in international circles—he was president of the International Astronomical Union from 1948 until 1952. He was also president of the International Council of Scientific Unions from 1952 until 1955. He received the Gold Medal of the Royal Astronomical Society in 1948.

RICHARD WOOLLEY

## NEWS and VIEWS

Commonwealth Advisory Committee on Advanced Education (Australia): Dr. I. W. Wark, C.B.E.

DR. I. W. WARK has been appointed chairman of the Commonwealth Advisory Committee on Advanced Education (Australia). Dr. Wark is at present a member of the Executive of the Commonwealth Scientific and Industrial Research Organisation. The Committee will make recommendations to the Commonwealth Minister in Charge of Commonwealth Activities in Education and Research as to the distribution of funds available for support of both capital and recurrent expenditure for projects recommended by institutes or colleges or State Governments and accepted by the Commonwealth as suitable subjects for support in colleges of advanced

education. The Commonwealth's decision to assist the States in developing advanced education facilities arose from its consideration of the report of the Committee on the Future of Tertiary Education. 'College of advanced education' is the title chosen for new tertiary colleges which will provide courses requiring an entry standard equivalent to university entrance and providing a diploma qualification on completion of such courses. These colleges will in many cases be developed from and around the tertiary sections of existing technical colleges in the States, and one of the Committee's principal tasks will be to encourage their development, not only in technology but also in the liberal arts. The Commonwealth's assistance to these colleges will be to strengthen and expand their diploma courses, but it does not intend to support finan-

cially their conversion into universities under another name.

Dr. Wark's appointment is a full-time one, and he will be assisted by a small number of part-time members. Dr. Wark has been a member of the Executive of the C.S.I.R.O. since 1961 and was formerly director of that Organization's Chemical Research Laboratories and the chief of its Division of Industrial Chemistry.

#### Principal of Chelsea College of Science and Technology: Prof. M. R. Gavin

PROF. MALCOLM ROSS GAVIN, professor of electronic engineering and head of the School of Engineering Science in the University College of North Wales, Bangor, since 1955, has been appointed principal of Chelsea College of Science and Technology and the vice-chancellor-elect of the new University. Prof. Gavin was educated at the Hamilton Academy, Glasgow, and the University of Glasgow, from which he graduated in mathematics and natural philosophy in 1929. He was awarded a D.Sc. degree by the University of Glasgow in 1949. After an early career in school teaching, he joined the Research Laboratories of the General Electric Co. (now the Hirst Research Centre) at Wembley. In 1947, he entered the Inspectorate of the Scottish Education Department. During 1950-55 he was head of the Department of Physics and Mathematics in the Birmingham College of Technology, where he was also vice-principal during 1953-55. Prof. Gavin was then appointed to the University College of North Wales, Bangor, where he has since built up a School of Engineering Science noted for its progressive approach to the education of applied scientists. He is a member of the Science Research Council and vice-president of the Institute of Physics and the Physical Society. He was a member of the Electronic Research Council of the Ministry of Aviation during 1960-64. Prof. Gavin has been closely associated with Chelsea College since 1964 as a member of the Academic Advisory Committee set up by the Governing Body in consultation with the University Grants Committee. Prof. Gavin succeeds Mr. C. C. Hentschel, who retires in September 1965 after thirty-four years, full-time service at the College. Mr. Hentschel became principal in 1962 on the death of Mr. N. M. H. Lightfoot, having previously been vice-principal since 1961 and head of the Department of Botany and Zoology since 1952.

#### Pathology in the University of Liverpool:

Prof. H. L. Sheehan

At the end of September, Prof. H. L. Sheehan will retire from the George Holt chair of pathology in the University of Liverpool to which he was appointed in 1946. At the time of his appointment he was already an authority on the pathology of pregnancy and the puerperium and had shown that necrosis of the anterior lobe of the pituitary gland, which commonly occurs during obstetrical shock, is a cause of chronic ill health in women that have survived an episode of obstetrical shock. During his tenure of the chair in Liverpool he clarified the clinical picture of post-partum hypopituitarism, now known as Sheehan's syndrome, and contributed monographs and many papers on the morbid histology and experimental pathology of renal cortical necrosis and hydronephrosis. His enthusiasm for clinical endocrinology and the importance of endocrine factors in cancerous conditions led to the establishment in Liverpool of an Endocrine Unit with Prof. Sheehan as director, and gradually the problems of neoplasia became one of his main interests; he plans to devote his official retirement to cancer research. Prof. Sheehan's effectiveness as a lecturer and his willingness and ability to lecture in foreign languages led to many invitations to lecture abroad; he has given many lectures in Europe on both sides of the Iron Curtain and in Australia, New Zealand and the United States. He is to

begin his 'retirement' with a series of lectures in South America.

#### Prof. J. R. Anderson

DR. J. R. ANDERSON has been appointed to succeed Prof. H. L. Sheehan in the George Holt chair of pathology in the University of Liverpool. Dr. Anderson graduated B.Sc. (1939) and M.D. at the University of St. Andrews (1955), gaining a University Gold Medal for his thesis on "Immune Antibodies in Haemolytic Anaemia". He was the first to produce in the rabbit haemolytic disease of the new-born that closely patterned human disease, and these studies led to extensive investigations on auto-immune disease in man, a field in which he is a recognized authority, with more than 30 publications mainly on the so-called collagen diseases. His work on non-tuberculous Addison's disease has helped to identify the site of formation of various adreno-corticosteroids. After initial experience in pathology with Prof. D. F. Cappell in Dundee, Dr. Anderson served for three years as a graded pathologist in the Royal Army Medical Corps, chiefly in west and north Africa. In 1947 he returned to rejoin Prof. Cappell, now in Glasgow, as lecturer and became senior lecturer in 1954 after a Rockefeller fellowship with G. H. Whipple and L. E. Young in Rochester, N.Y. Dr. Anderson is a lucid and interesting lecturer who has had a wide experience of undergraduate and postgraduate teaching and examining; his publications (with Dr. Lennox) on the use of multiple choice papers (1957) and on selection procedures in the light of students' examination performance (1964) have attracted much attention. His extensive experience of hospital diagnostic pathology has given him an enviable reputation as a sound opinion in such matters, which is much sought by his clinical colleagues.

#### Director of Research, Marconi Company:

Mr. G. D. Speake

MR. G. D. SPEAKE has been appointed director of research in the Marconi Company. Mr. Speake was formerly chief of research at the Great Baddow Research Laboratories, and development manager for the Radar Division. This new appointment will enable Mr. Speake to concentrate on the task of reorganizing and strengthening the research activities of the Company. George David Speake was born in 1919 in Newport, Shropshire. He was educated at Adams Grammar School, Newport, and took his degree in physics at St. Catharine's College, Cambridge. He joined the Marconi Company in 1950 and was engaged in Radar Systems Research until 1954, when he was appointed chief of the Vacuum Physics Section of the Research Division. Two years later he became chief of the Microwave Physics Section, and in 1960 he was appointed deputy chief of research under Dr. E. Eastwood. In 1962, when Dr. Eastwood was appointed director of engineering and research for the Company, Mr. Speake became chief of research, and he has remained in this position until this new appointment. Before joining the Marconi Company, Mr. Speake was a flight-lieutenant in the Technical Branch of the Royal Air Force, and, later, instrument manager in the Plastic Division of Imperial Chemical Industries, Ltd.

#### Government Advisory Committees

IN a written answer in the House of Commons on February 28, the Prime Minister gave Mr. P. Dean a list of 241 advisory committees, most of which had been set up during this century, and more than half of which had been established since the Second World War. Since that question was raised, the Advisory Council on Scientific Policy has become an executive body, a Social Research Council has been established, and so also an Advisory Committee for Scientific and Technical Information. Accordingly, Mr. Dean raised the question of Standing Advisory Committees in an adjournment debate on

July 28. He suggested that while these committees had an important part to play in Britain's system of government, particularly in regard to scientific and technical advice, it was desirable to take a closer look at the part they play, the way in which they were developing and their constitutional significance. Mr. Dean said that besides increasing in number, the scope of the Committees was tending to widen so that they dealt increasingly with major aspects of policy and advised on a much broader front than many of the early committees, which were largely technical or specialist. He challenged the necessity for the reports of many of these committees to be confidential, citing some obvious examples of discrepancy.

Mr. N. MacDermot, the financial secretary to the Treasury, who replied for the Government, agreed that advisory committees were a valuable institution of government, but did not think that at present there was any burning issue calling for official examination of the scope and activities of these committees. If a review of their activities was desirable, he thought that the Estimates Committee might be a suitable body to undertake such an investigation, unless it was desirable to appoint an outside body. On the cost of these committees, Mr. MacDermot said that the total cost in remuneration and expenses was about £150,000 a year, in addition to the secretarial services provided for them, which cost a further £280,000. There had been no change in the policy regarding publication of reports, but he pointed out that care should be taken to avoid confusion between the role of Ministers, on one hand, and that of the advisory committees, on the other. Whether the advice was published or not was the responsibility of Ministers on whom responsibility for policy also rested: publication of the advice tended might sometimes exert pressure on Ministers. He thought it was undesirable to make it an invariable rule that the advice of committees must be published, as we might thereby find ourselves deprived of some of the freedom we now had in obtaining expert opinion. Neither Mr. Dean nor Mr. MacDermot referred to the study of advisory committees published in 1960 by Political and Economic Planning or to the earlier study of the use of "Committees in Government", published in 1955 by Prof. K. C. Wheare.

### The Nature Conservancy

In a written answer in the House of Commons on August 2, Mr. A. Croxall, the Secretary of State for Education and Science, stated that he had approved proposals submitted by the Natural Environment Council for senior headquarters staff serving the Nature Conservancy. The next director of the Conservancy would be a scientist appointed at the upper level of the chief scientific officer grade (£4,700) and would be supported by a deputy director for the organization and planning of research, and a deputy director for conservation and management. The former would be a scientist at deputy chief scientific officer level and the latter either a scientist at the same level or an administrator at assistant secretary level. These proposals were prepared by a working party, headed by the chairman of the Council, Sir Graham Smith, and were endorsed by the Council and carried the full support of the chairman of the Conservancy.

### Towards a Manpower Grid

There is a growing realization that, in raising productivity from the recent levels of 1.5-2 per cent to the 3.5 per cent national target, efficient utilization of industrial manpower plays a critical part. International comparison with other leading industrial countries implies that British management is wasteful in its use of manpower. Viewed from the other angle, restrictive working practices make worse a regressive situation. The apparent full employment of the British economy is, in fact, a

spurious interpretation of the real employment situation. Present high employment is falsely bolstered by the over-manning of the profitable sectors of the industry, and retention of labour in industries that have ceased to be fully economic. The degree of real under-employment that this involves is variously estimated; however, qualified observers consider that the elimination of it would release between 10 and 15 per cent of the industrial work force for re-deployment into other work. If Britain is to remain internationally competitive during the next decade, her industry will have to make real inroads into this manpower problem. An article by Michael Hall, manager (recruitment and manpower), Esso Petroleum Co., Ltd., directs attention to the need for more efficient instruments and methods of manpower planning at all levels in industry and at the national level (*Personnel Management*, 47, No. 372; June 1965). Without improved data sources or manpower forecast techniques, it is difficult to see how the massive labour movements, between skills, localities of employment or between employers, that the present economic analyses imply to be necessary can be achieved.

### Education of Engineers in Western Germany

In a lecture delivered at the summer meeting of the Institution of Mechanical Engineers at Wiesbaden, Western Germany, in June, Dr. G. Branken described the education of professional engineers in Western Germany. He began with the school system which feeds the technical schools, whether Technische Mittelschule, Technikerschule or Technische Hochschule. One of the two qualifications of a professional engineer is the Diplom-Ingenieur, obtained after third-level engineering education in Technische Hochschule, normally by a four-year course. Practical training in industry is a prerequisite condition of entry. In 1964, there were 55,000 students in the nine Technische Hochschulen and 4,500 graduates, compared with 13,500 graduates from the 122 Ingenieurschulen with their 52,472 students in three-year courses, and 8,000 graduates from the 220 Technikerschulen with their 30,000 students, which provide day courses of a year and a half and 3-4 years in evening classes for technicians. Most of the professional engineers are later placed in design and planning; only 10 per cent are placed in research and development. The academic education of engineers at Technische Hochschulen has been extended by one to two years over the past fifteen years, although at most of the Hochschulen the courses are still four years (*Proc. Inst. Mech. Eng.*, 179, Part 4; 1964-65).

### Institution of Production Engineers

The *International Journal of Production Research*, published by the Institution of Production Engineers, is a quarterly periodical now beginning its fourth year, and in the latest issue an editorial note deservedly chronicles achievements since its inception (4, No. 1; 1965). The University, Birmingham 15, and 10 Chesterfield Street, London, W.1). First, this *Journal* is truly international in that its advisory board consists of distinguished members from many parts of the world, and it now circulates in forty countries; secondly, it is a useful link between research workers through which progress may be reported and new ideas generated; thirdly, it covers fields of study to-day recognized as constituent parts of production engineering. Among the papers in the present issue are: "The Ductile-Brittle Transition when Machining Perspex", by R. F. Scrutton, which identifies the conditions under which 'Perspex' can be machined in a ductile manner avoiding troubles often incurred with this and other brittle plastic materials; "A Case Study of Programmed Instruction in a Self-Correcting Teaching System in an Apprentice Training School", by B. T. Dodd, concerning accelerated training methods designed to reduce the period of craft apprenticeship from five to four

years; "Work Sampling using Extended Observations", by E. N. Corlett and R. H. Hollier, describing 'snap sampling' as applied to estimations of proportions of time spent in activities by operators and machines, but with an extended technique to provide idle time distributions, and the method involved; "Mechanics of Chip-breakers", by T. L. Subramanian and A. Bhattacharyya, deals with the problem of chip disposal now more acute with the introduction of high-speed carbide and ceramic tools, and presents a physical explanation of behaviours of the cutting variables encountered; W. A. Morcos contributes an article on the complex problem of "Interchangeability of Screw Threads: a Study of the Effective Diameter Equivalent of Flank Angle Errors for a Basic Taper Thread", with appropriate mathematical treatment and new methods of determination; a paper on "Classification of Pacing", by K. F. H. Murrell, explains the part played by tolerance in the classification and the relationship between tolerance and machine rate. With each contribution an appropriate synopsis in both French and German is included.

#### A. P. Sloan Foundation

THE report of the A. P. Sloan Foundation for the two years 1963-64 records commitments authorized by the Trustees of 30.4 million dollars. In support of basic scientific research, 5 million dollars went to the Massachusetts Institute of Technology to establish a special institutional research fund, and 1 million dollars to four mid-continent universities to strengthen their science facilities and teaching. The level of expenditure in the Foundation's fellowship programme for basic research in the physical sciences was increased from 1.2 million dollars to 1.4 million dollars, beginning in 1965. For the academic year 1963-64 there were 144 Sloan Research Fellows in 49 institutions in the United States and in Canada, compared with 155 in 48 institutions in September 1964. A grant of 1 million dollars was authorized for the new Mathematics Centre at Stanford University and one of 5 million dollars for Massachusetts Institute of Technology to establish a pioneering programme of continuing education for experienced engineers. Virtually all the Foundation's grants for cancer research (totalling 1.4 million dollars) went to the Sloane-Kettering Institute for Cancer Research in New York and to affiliated programmes; however, grants were also made for research in glaucoma and urethritis and an initial grant for a programme of research in otology. The Sloane National Scholarship Program now embraces 45 universities and colleges and totals 1.28 million dollars: a special grant of 500,000 dollars was made to the United Negro College Fund in 1963, as well as 200,000 dollars to other projects for strengthening educational opportunities for Negro students. A grant of 1 million dollars was made to Stanford University to complete a new Centre for its Graduate School of Business, and other grants in the same field were to the Columbia University Graduate School of Business, the Tuck School of Business Administration of Dartmouth College, and the Sloan School of Management of the Massachusetts Institute of Technology. Grants for economic research and education (mainly to the National Bureau of Economic Research) exceeded 1 million dollars and commitments for improving the public understanding of science totalled 275,000 dollars. In June 1963 a grant of 100,000 dollars was made to the United States Churchill Foundation for scholarships and fellowships.

#### Education In Forestry

UNDER the title *Education in British Forestry* a report of the fifth discussion meeting organized by the Society of Foresters of Great Britain has been issued as a supplement of the Society's journal, *Forestry* (Pp. 74. London: Oxford University Press, 1965. 7s. 6d.). The discussion

was held at Cirencester during January 8-10, 1965, and the three sessions dealt with the education of foresters; the education of forest officers; and with forestry education for the wider field. Besides Prof. M. V. Laurie's opening address and the text of the ten papers contributed, the report includes summaries of the discussion in each session and Mr. J. J. Lawrie's closing remarks in which he referred to responsibilities towards Voluntary Service Overseas and to the opportunity afforded by the conference, "The Countryside in 1970". There was some frank criticism of British forestry education below university level and a resolution was passed recommending the Council of the Association, in co-operation with the Forestry Commission and other interested bodies, to investigate the establishment of institutions suited to both State and other forestry interests. At the university-level the meeting was impressed by advances in recent years, by the scope of present curricula, and by the lively outlook.

#### Scientific Societies In India

*A Survey of Scientific Societies in India*, by A. Rahman, N. Sen and N. R. Rajagopal of the Survey and Planning of Scientific Research Unit, has been published by the Council of Scientific and Industrial Research, New Delhi (Pp. 40. New Delhi: Council of Scientific and Industrial Research, 1965). Data were collected on the organization and role of such societies with the view of correlating them with the scientific and technological development of the country. Prior to 1930 there were few such societies and of the 27 listed 22 were established for specialized fields, 10 being concerned with engineering and technology. During 1931-50 the number of societies increased three-fold in the physical sciences and in the medical and biological sciences, and doubled in engineering and technology; this is attributed largely to the development of a base for research in the country. From 1951 onwards the trend to establish more scientific societies continued to increase, and is marked by the establishment of such highly specialized societies as the Indian Cancer Society, the Indian Society of Haematology, the Indian Society for Helminthology, the Institute of Telecommunication Engineers, the Indian Society for Rayon Technologists, the Indian Leather Technologists Association and the Institute of Information Scientists. The societies are heavily concentrated in cities like Calcutta, New Delhi, Bombay, Bangalore and Madras, where 118 out of 150 are located and only 54 per cent have a membership of 100 to 500. Only the Institution of Engineers, India, with 42,887, has more than 5,000 members. Almost 90 per cent issue periodicals and more than 31 per cent receive financial support from the Central Government, about 80 per cent from State Governments and about 18 per cent from industry. Of the 103 societies giving figures for income and expenditure, about 36 per cent had annual incomes by 1962 of 10,000-50,000 Rs., and some 7 per cent an income of less than 1,000 Rs. The total membership of 115 societies out of the 150 is about 95,000 compared with a total of postgraduate scientists, medical graduates and engineering graduates of about 188,000.

#### Journal of Labelled Compounds

THE first number of the new quarterly *Journal of Labelled Compounds* contains eight original contributions, one German, three French and four English, with English summaries, together with a section containing abstracts of 67 papers dealing with the synthesis of labelled compounds and related compounds (1, No. 1, January-March, 1965. Pp. 1-92. Brussels: Presses Académiques Européennes, 1965. Annual subscription: B.F.I.250; 25 dollars). The editor of the *Journal* is J. Sirchia of Euratom (Brussels) and there is an editorial board consisting of twenty members. The abstractor is H. Dworschak of the Information and Documentation Centre, Euratom. Two of the

articles, written by members of the Division of Pure Chemistry, National Research Council, Canada, deal with deuterated organic compound synthesis, and two, by members of the University of Rome, with self-radiolysis of tritium-labelled compounds. L. Pichat, M. Herbert and F. Aubert of Saclay describe a new method of preparation of glycerol  $1-^{14}\text{C}$  and glyceric acid  $1-^{14}\text{C}$ . W. G. Verley and C. Gerday of the University of Liège discuss a method for the evaluation of the radiochemical purity of the labelled isomer of an amino-acid which they have applied to tritiated L-phenylalanine. Only a small sample is required but very minute contaminants can be detected.

#### Publications of the International Atomic Energy Agency

THE International Atomic Energy Agency, in addition to its many scientific activities, is now one of the largest publishing enterprises in Vienna. It has recently completed its sixth year of publication of literature dealing with the peaceful uses of atomic energy. In 1959 its output was two volumes in the *Proceedings* series, one in the *Safety* series and four technical directories, in addition to those publications prepared for free distribution, but to-day its average annual production consists of about twenty volumes of the proceedings of scientific meetings, six technical directories, several bibliographies and numerous technical reports. Two scientific journals, *Atomic Energy Review*, a four-language periodical published at irregular intervals, and *Nuclear Fusion*, a quarterly devoted to plasma physics and power from the fusion of light nuclei—together with the monthly *IAEA Bulletin* which describes the activities of the Agency in more general terms—are also published. Some publications are issued in multilingual form, others in each of the four working languages—English, French, Russian and Spanish—of the Agency. Since 1963, when printing and binding equipment was installed, the Agency has printed and bound all its own publications except the journal *Nuclear Fusion* which is separately managed in Vienna by a scientific editor and supervised by an editorial board. An up-to-date catalogue, *Publications in the Nuclear Sciences 1965*, listing all the priced publications of the Agency, either currently available or in the press, is available free of charge on request (Pp. 99. Vienna: International Atomic Energy Agency, 1965). It supersedes all previous catalogues and supplements. The titles are grouped under general subject headings: biology, medicine and agriculture; health, safety and waste disposal; physics, plasma physics and electronics; chemistry, geology and raw materials; reactor physics and reactors; industrial applications; economics; and law; corresponding to the separate activities of the Agency. They are listed in inverse order of publication, with the most recent first. Each item, in addition to the title and author, gives a summary of the contents, the language or languages, and the retail price in both dollars and sterling. Those publications which are also part of a series publication of the Agency are listed again in the "Series Index" which forms the second half of the catalogue. A list of sales agents and a title index complete the catalogue.

#### Bibliography on the Commonwealth and Its Constituent Countries

No. 45 of the *Special Subject Lists* issued by the Library Association, which is entitled *The Commonwealth To-day*, is a select bibliography on the Commonwealth and its constituent countries (By A. J. Horne. Pp. 107. London: The Library Association, 1965. 24s.; L.A. Members 18s.). There is a foreword by Sir Kenneth Bradley and the list is admirably printed and arranged. It includes no periodicals and only a few government publications, being limited mainly to books published in recent years and still in print. That qualification is doubtless the reason for some surprising omissions, and it is the shortcomings

of the book trade to-day that are displayed rather than weaknesses in selection. Titles are arranged on a geographical basis, by continent and country, and Mr. Horne has supplied an excellent and useful bibliography. While there are undoubted advantages in limiting a bibliography to books in print, the disadvantages of this practice have probably never been so marked as at the present time.

#### Bibliography from the Institute of Nutrition, Budapest

INSTEAD of the year-book, the Institute of Nutrition Budapest, has published a bibliography listing the titles of the various publications, etc., produced by its scientific members during 1964 (*Bibliography of Publications 1964*, Institute of Nutrition, Budapest, Hungary. Pp. v+21. 1965). The sources from which the titles are drawn include papers published in Hungarian and other journals, books, dissertations for degrees, contributions at congresses and lecture notes. The 81 headings cover a wide range of subjects such as the fatty acid composition of milk powder, radioactivity in milk, the application of polarography to amino nitrogen and oxytetracyclines, vitamin status and protein requirements in humans, food colour, food poisoning and hygiene. Each heading in the bibliography is given in three languages including English.

#### Synthetic Emerald

ATTEMPTS at the synthesis of many gemstones have a long history in appropriate technical literature, including emerald; latterly, beryllium and its compounds have assumed considerable economic importance in fields unsuspected only a few years ago. Scientists in the Hughes Aircraft Co., Culver City, California, have been working on synthetic emerald production since 1961 with an encouraging measure of success; the spur for this work stemmed from the need for large high-quality single crystals of emerald that could be grown rapidly; in the field of solid-state physics, for example, they find use in such devices as millimetre-wave masers. An interesting account of this work, brief but informative, is presented in the house journal *Vectors*, a quarterly publication by Hughes Aircraft Company (7, No. 1, 1965). Hitherto what is known as the flux-fusion process for synthetic emeralds has been used, but the Hughes scientists have developed a flame fusion technique which "... can produce an emerald 'boule' (pear-shaped mass of a substance formed synthetically in a special furnace) in a matter of several hours, as compared with the many months required by the flux fusion process". The flame fusion process involves beryllium oxide, a highly toxic substance, and special isolated laboratory facilities are requisite because of the poisonous vapours evolved; the other oxides concerned are those of aluminium and silicon, the proportions (by weight) being given as: beryllium, 16 per cent; aluminium, 18 per cent; silicon, 67 per cent. A minute quantity of chromium oxide is added to the mix to provide the emerald colour. The mixture is placed in one-gallon jars, rolled on a ball mill rack for 8 h, then sintered at  $1,050^{\circ}\text{C}$  for five days. The resulting powder is fed to the flame fusion unit comprising an oxy-hydrogen burner capable of a temperature of  $2,800^{\circ}\text{C}$  and appropriate cooling facilities. "The powder mixture, fed in from a hopper at the top, flows through the centre tube of the burner accompanied by a stream of oxygen to a ceramic pedestal where the boule grows". These Hughes emeralds are about 0.5 in. long and 0.25 in. diameter, blue-green in colour. X-ray photos show them to be indistinguishable from those of natural emeralds. These man-made gems are, incidentally, produced at a cost of not more than one-fourth to one-third that of the natural stones.

#### Sugar Research In Mauritius

THE annual report of the Mauritius Sugar Industry Research Institute for 1964 is the record of a very credit-

able effort (Pp. 117+xxxii+xxii. Reduit: Mauritius Sugar Industry Research Institute, 1965). However, 1963 was an unfortunate year for Mauritius and the report shows up clearly the great risks involved in tropical agriculture. The area of land under sugar cane was much the same in 1964 as in the previous year, but "A combination of negative factors, dominated once more by the occurrence of two cyclones, were responsible for an overall sugar production of only 520,000 tons, which was below that of the previous year by 24.2 per cent". Among the negative factors stands out the dangerous fact that "Two major diseases, gummosis and leaf scald, which had been totally eradicated from commercial fields, reappeared in epidemic form and are believed to be caused by new and more virulent strains of the pathogens". Only to the continuous work of the Research Institute and its constant search for disease-resistant new cane varieties is it due that "A varietal replacement programme can be designed which should not adversely affect the present sugar potential of the island". The great majority of the report is devoted to the cultivation of the sugar cane and to its diseases and pests; only 15 pages deal with problems of sugar manufacture and a single article (3 pages) mentions an unpromising by-product.

#### The Linnean Society of London :

##### Foreign Members

DR. E. I. WHITE, president of the Linnean Society of London, announced at the general meeting on April 22 that the following foreign members had been elected: Dr. S. M. Bukasov (U.S.S.R.); Prof. A. Frey-Wyssling (Switzerland); Prof. C. L. Hubbs (United States); and Prof. J. Leonard (Belgium).

##### Awards and Medals

THE following medals were awarded: The *H. H. Bloomer Award and Medal*, to E. C. Wallace; *Linnean Gold Medals* to Dr. J. Hutchinson and Dr. J. Ramsbottom.

##### Officers

THE following officers were elected: *President*: Dr. E. I. White; *Treasurer*: The Earl of Cranbrook; *Botanical Secretary*: Mr. J. P. M. Brenan; *Zoological Secretary*: Dr. H. G. Ververs; *Editorial Secretary*: Dr. J. Smart.

##### Vice-Presidents

THE following were elected vice-presidents for the session 1965-66: The Earl of Cranbrook, Prof. C. T. Ingold, Dr. R. W. J. Keay and Dr. Doris M. Kermack.

#### Society for Applied Bacteriology : Officers

At the annual meeting of the Society for Applied Bacteriology the following officers were elected: *Honorary President*, Dr. Joan Taylor; *Honorary General Secretary*, Dr. J. R. Norris; *Honorary Meetings Secretary*, Dr. Ella M. Barnes; *Honorary Treasurer*, Mr. G. E. Jones; *Honorary Editors*, Dr. F. A. Skinner and Mr. G. Sykes; *Honorary Publications Manager*, Mr. A. H. Walters; *Members of the Committee*, Dr. F. W. Beech, Miss Vera G. Collins, Dr. Ann W. Cooper, Dr. Christina M. Cousins, Mr. B. M. Gibbs, Dr. Elizabeth M. Harper, Dr. R. M. D. Keddie, Mr. D. A. Shapton and Dr. P. D. Walker.

#### Perkin Centenary Awards, 1966-1967

APPLICATIONS for the award of Perkin Centenary scholarships are invited by the Perkin Centenary Trust. Awards, tenable for one or two years, and renewable for a further year at the discretion of the Trustees, are offered to candidates employed in an industrial firm or other institution concerned with the manufacture or the application of colouring matter, for study at a university or technical college. Two types of award are available, some to the value of £100, which are to be used in conjunction with a local education authority grant, and

others to a value of £400, which are intended for students whose normal grant, inclusive of fees, would be less than about £300. Perkin travel grants are also available to teachers concerned with the study of any aspect of the manufacture or the application of colouring matter. Applications for the scholarships must be made by May 1, 1966, and for the travel grants by December 31, 1965. Further information can be obtained from the Secretary, the Perkin Centenary Trust, c/o the Chemical Society, Burlington House, London, W.1.

#### The Journal of the Franklin Institute Premium

*The Journal of the Franklin Institute* has established a special Journal Premium of 1,000 dollars. It is to be awarded annually to the author of the outstanding paper published in the *Journal* during the preceding year. The award will be presented, in general, to the recipient of the Louis E. Levy Medal. Established in 1923, the Levy Gold Medal is awarded by the Franklin Institute "to the author of a paper of special merit published in the *Journal*, preference being given to one describing the author's experimental and theoretical researches in a subject of fundamental importance". *The Journal of the Franklin Institute* was established in 1826 and is the oldest continuing scientific publication in the United States. It accepts contributions in all traditional branches of mathematics and the physical sciences, pure and applied, as well as in interdisciplinary fields or composite sciences that combine the philosophies of two or more disciplines. Consideration for the Journal Premium will be given for the first time to papers published during the calendar year 1965.

#### Announcements

PROF. G. A. OLAH, research scientist with the Eastern Research Laboratory of the Dow Chemical Company, has been appointed professor of chemistry and chairman of the department at Western Reserve University.

AN international conference on "Elementary Particles" will be held in Oxford during September 19-25. Further information can be obtained from the Rutherford High Energy Laboratory, Chilton, Didcot, Berkshire.

THE autumn meeting of the Institute of Metals will be held in Grenoble during September 19-25. Further information can be obtained from the Secretary, Institute of Metals, 17 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "Electromagnetic Flow Measurement" will be held in the University of Warwick on September 24. Further information can be obtained from the Administrative Officer, School of Engineering Science, University of Warwick, Coventry.

A SYMPOSIUM on "Chemistry of Plant Pigments", organized by the Phytochemical Group, will be held at the University of Aberdeen during September 23-24. Further information can be obtained from the A. H. Williams Research Station, Long Ashton, Bristol.

AN exhibition of modern packaging methods and machines for the textile industry will be held at the Northern Ireland Linen Research Institute, Lisburn, during September 14-16. Further information can be obtained from the Linen Research Institute, Lambeg, Lisburn, Co. Antrim.

**CORRIGENDUM.** In the article entitled "Fundamental Equations governing the Hit Probabilities associated with the Release of a Pattern or Group of Weapons using a Single Aimpoint" by Dr. E. R. Terry, which appeared on p. 1135 of the June 12, 1965, issue of *Nature*, equation (10), which reads " $(\xi, \eta) = \dots$ ", should read " $f(\xi, \eta) = \dots$ "; moreover, equation (21) should read:

$$S_j^{(n)} = \sum_{k=j}^n \binom{k-1}{j-1} Q_{n,k} = \sum_{k=j}^n \binom{k}{j} Q_{[n,k]} \dots$$

## GAS CHROMATOGRAPHY

AN informal symposium organized by the Gas Chromatography Discussion Group of the Institute of Petroleum was held on March 12, 1965, in the Edward Lumley Hall of the Royal College of Surgeons, Lincoln's Inn Fields, London, with Mr. D. H. Desty in the chair. The symposium, which was preceded by the annual general meeting of the group, opened with Dr. D. W. Hill formally welcoming the visitors on behalf of the Royal College and describing some of the applications of gas chromatography in his own field.

In the first paper, entitled "Temperature Control in Gas Chromatography", presented by Dr. H. V. Carter (Perkin Elmer, Ltd.), the desirability of good temperature control was stressed particularly in the case of thermal conductivity detectors where a change in temperature as small as  $0.001^\circ\text{C}$  produces visible base-line shifts. In his discussion on types of heating systems, Dr. Carter stated that when the main consideration is negligible temperature gradient at low cost, a vapour jacket is most suitable although it has the disadvantages that the temperature is affected by pressure ( $0.4^\circ\text{C mm}^{-1}$ ) and a change in level is not conveniently made. When very tight temperature control is essential direct electric heating using the column itself as the element is suitable particularly for temperature programming because there is no time lag. Although this system is probably the best available, the user is restricted in his choice of column since its resistance must lie between defined limits. Moreover, temperature gradients are difficult to control if the column has variable thickness, although this can be overcome by removing metal from the column or varying the insulation where necessary. Proportional, on-off and programmed systems were discussed and illustrated by reference to commercial instruments and this was followed by detailed evaluation of the air-bath. While temperature control is difficult and acceptably low-temperature gradients are only obtainable with very high air velocities there is very little restriction to the dimensions of the oven and access to the column is generally very good. A method of calculating temperature gradients was described and shown to give values slightly lower than those obtained in practice. Dr. Carter concluded his paper with a brief review of the methods used for sensing changes, and the merits of thermocouples, bimetal strips, thermistors and platinum resistance thermometers were compared. Discussion of this paper evolved mainly around the geometry of systems and insulation problems, during which Dr. Carter discussed in some detail the properties of the platinum resistance thermometer and mention was made of the good oven control obtained by using a bimetallic strip as a transducer.

The second paper, on "Errors in Integration in Gas Chromatography", by Mr. W. A. Wiseman of Gas Chromatography, Ltd., was given in his absence by Dr. A. B. Littlewood. Integration errors were divided into two classes, fundamental and instrumental. It was pointed out that the area ( $A$ ) of a chromatographic peak can be measured by integrating the signal ( $E$ ) due to the detector with respect to time:

$$E = k_0 + (k - k_1)y + k_2y^2 \quad (1)$$

$$A = k_0x + (k - k_1)z + k_2\int(dx/dt)dt \quad (2)$$

where  $x$  is a measure of the detector signal (for example, charge) and  $y = dx/dt$  (for example, current).

The first and third terms of equation (2) are responsible for the sources of error in the method, the constant  $k_0$  being responsible for those incurred due to incorrect setting of the base-line, and  $k_2$  for those due to non-linearity of the detector control. The constant  $k_0$  is a function of  $a/h$ , where  $a$  is the decrease in peak height  $h$  due to incorrect

setting of the base-line: in order to obtain accurate results  $a/h$  must be only a few parts per thousand. Large errors, which increase with the width of the peak, are caused by a drifting baseline and together with the error caused by incorrect setting of the base-line represent the largest error found in integration. Errors due to non-linearity of the detector increase with increasing peak height as does the ratio of the height to the area. If accurately reproducible samples are injected into the system at differing output sensitivities using a mixture giving a number of different peak heights, the ratio of dissimilar peaks should be constant. Peaks showing up early in the analysis occur at maximum rate at which impulses appear leading to an inherent, but small, error in the analysis.

Dr. Littlewood then considered errors in instrumentation. Integration is initiated by the appearance of a peak and this may be registered either when (1) the base-line exceeds a certain minimum, or (2) the slope exceeds a certain minimum; in both cases, however, a slight error is introduced at the beginning and end of a peak. In general, slope initiation is better than base-line initiation but difficulty is encountered when studying wide shallow peaks and a mechanism combining both modes of initiation was suggested as worthy of consideration. When integration is applied to partially resolved peaks meaningful results can only be obtained when there is a deep valley between them. In the ensuing discussion references were made to the importance of the right rate of counting, that results were calculated and not measured directly for non-linear integrators, that normalizing techniques should be used for accurate evaluation of results and that electronic integrators eliminate many of the errors mentioned.

Mr. R. Gittins (W. G. Pye and Co., Ltd.) introduced his paper on "The Evaluation of Performance of Flame-Ionization Detectors" by commenting on the value of the development work carried out by instrument manufacturers. Because of the difficulties involved in sampling very small masses the performance of high-sensitivity detectors had been studied using a vapour dilution vessel containing the sample under investigation dissolved in a non-volatile liquid (compare Fowles, I. A., and Scott, R. P. W., *J. Chromatog.*, 11, 1; 1963). Detector response was found to be independent of air flow above 400 ml.  $\text{min}^{-1}$  (below this value linearity occurs over a narrow range of concentration due to incomplete combustion) and independent of applied voltage above 20 vol. (45 vol. used in practice). The hydrogen to carrier gas ratio was found to exhibit optimum values.

"Dual Channel Gas Chromatography" was the title of a paper presented by Mr. P. Jenkins (Wilkins Instrument and Research A.G.) in which, after a résumé of the useful combinations of gas chromatography and other techniques was given, the complementary nature of the electron capture and flame-ionization detectors was described and illustrated by examples obtained with an instrument incorporating both. By splitting a column effluent into two streams, one to feed each detector, simultaneous though different chromatograms could be obtained: thus a sample of butyl phenol gave one peak (butyl phenol) on the flame ionization trace and five other peaks (impurities) on the electron capture trace: a refinery stream gave propane and propene on the former and oxygen, carbonyl sulphide, carbon disulphide and carbon dioxide peaks on the latter. The electron capture detector is unpredictable in its response to chemical compounds and is probably not linear although under standard conditions the ratio of peak heights flame ionization to electron capture may be used as an aid to identification. Problems of instrumentation and design were discussed with particular reference to the choice of voltage for the electron capture detector and considerable

interest was shown in the ability of the detector to respond to oxides of nitrogen.

The final paper, "Abnormal Characteristics of the Ionization Cross-section Detector", was presented by Mr. P. F. Washbrooke (The M.E.L. Equipment Co., Ltd.). After discussing briefly the main characteristics and modes of operation of ionization detectors, Mr. Washbrooke reported fully on cross-section types and the behaviour with reference to (1) the selection of carrier gas, (2) flow rate of carrier gas, (3) temperature, (4) linearity of response, and (5) predictability of sensitivity. A micro cell had been constructed in which the electrode arrangement was a cascade system in which the tritium electrodes were off-set with respect to each other in such a manner that the effective radiation surface area was increased with very little increase in cell volume. Hydrogen and nitrogen had been found satisfactory as carrier gases: helium and argon, although they could be used, responded more readily to other ionization effects (for example, drift effects). Response variations due to voltage changes had been considered and in particular it was found that unless oxygen in nitrogen carrier gas was subjected to suitably high voltages it responded to an electron capture effect. Detector response was found to be dependent on the rate of mass input, independent of carrier gas flow rates between 10 and 100 ml. min<sup>-1</sup> and independent of temperature up to the safe working limit of tritium (200° C). The linearity of response, which depends on energy losses in the primary radiation stages,

is linear over many orders of magnitude for tritium as well as strontium-90 if the interelectrode path is small compared with that of a  $\beta$ -particle, and it is important to note that the detector can handle sample sizes considerably larger than any other type. Predictable relations have been obtained between peak area responses per millimole and values calculated from molecular cross-sections for *n*-paraffins, alcohols and monocarboxylic esters, but large deviations occur for aromatic hydrocarbons, aliphatic ketones and halogenated hydrocarbons. When quoting responses the radiation source should be given, as differences of up to 16 per cent are obtainable for cross-sections examined by different radiations. Changes in temperature may also affect the response characteristics. Mr. Washbrooke concluded his presentation by stating that the cross-section ionization detector is ideal for on-stream monitoring in preparative-scale gas chromatography when used with hydrogen or nitrogen carrier gas in order to minimize electron drift effects. The discussion was opened by Dr. H. Boer, who spoke of the anomalous behaviour of helium as carrier gas and mentioned his own version of a micro cross-section detector which had given excellent results for the detection of low boiling compounds. The remainder of the discussion was concerned with the use of the detector in the analysis of town's gas, the advantage of using argon as carrier when permanent gases were to be detected and the saturation of helium carrier gas with water to remove drift effects.

## INTERNATIONAL ATOMIC ENERGY AGENCY

AT its meeting in February, the Board of Governors of the International Atomic Energy Agency gave approval for the nearly one hundred projects of assistance by Agency experts and equipment in thirty-eight countries to be financed from Agency funds under the 1965 Programme. This is in addition to the work financed under the United Nations Expanded Programme of Technical Assistance. The number of requests for experts and equipment continues to increase, largely because several member states have now set up research reactors and established laboratories under bilateral arrangements. For 1965 the estimated cost of the provision of experts and equipment from Agency resources is 874,000 dollars, of which about one-third is for equipment and supplies. The work covers a wide range; about thirty projects deal with the production of radioisotopes and their application in medicine, agriculture, hydrology, food preservation and industry, and the remainder are concerned with reactors, health and safety, instrumentation, special branches of chemistry and physics, and the prospecting and processing of raw materials.

In Africa, the Congo is enlarging its research reactor and laboratories to form a regional centre and the Agency is providing an expert on nuclear electronics and a radiobiologist. Ghana is completing the construction of an experimental reactor at its nuclear research institute near Accra and will be assisted by a reactor programme

specialist and a nuclear physicist. Morocco's geological service is to be helped by the introduction of geochronological methods, and Tunisia is to receive advice on aerial prospecting for nuclear raw materials. Senegal, Rhodesia and the United Arab Republic are to be given help on the use of radioisotopes.

Equipment consisting of a pulsed neutron source and a pulsed neutron logic unit, together with assistance in reactor physics, are to be given to Argentina, and in Chile a biophysicist will advise on the development of electron spin resonance and its applications. Bolivia, Brazil, Mexico, Peru and Uruguay are also to receive expert assistance and advice. In Europe and the Near East, Afghanistan, Greece, Iran, Israel, Lebanon, Portugal, Turkey and Yugoslavia will all be visited by various nuclear scientists. In South-east Asia and the Far East, Burma will be sent standard works on nuclear physics and engineering; Cambodia and Ceylon advice and equipment relating to the use of radioisotopes; the National University Hospital in Taiwan, China, advice on the use of its cobalt teletherapy unit; Thailand an entomologist and equipment to undertake the study of the use of radiation for the control of insect pests; and India, Pakistan, Hong Kong and Viet-Nam experts for agricultural and food preservation research and assistance in teaching programmes.

S. WHINTROUB

## THE AMERICAN OYSTER

FOR some forty years Dr. Paul Galtsoff has served as shellfish biologist with what is now the U.S. Fish and Wildlife Service. Of recent years, while holding the post of senior scientist in that Service, he has been engaged on the production of a comprehensive account of the American oyster, *Crassostrea virginica*. He has had the initial benefit

of the widest experience of both laboratory and field investigations, his work on reproduction in *C. virginica* is classical while, as he tells us, he has studied oysters and related bivalves off every coastal State in the United States, in the Hawaiian Islands, in the Gulf of Panama and on Margarita Island, Venezuela.

The final result of his long experience and more recent intensive study of the literature—one hopes to his own great satisfaction but most certainly to that of all who are interested in oysters in particular and in bivalves and indeed marine biology in general—has now been published\*. Occupying an entire volume of the *Fishery Bulletin*, it is almost 500 pages long with 400 text figures, a wealth of references and an excellent index.

The species of *Crassostrea*, which include the Portuguese and Japanese oysters, *C. angulata* and *C. gigas*, are the most important of all edible bivalves. *O. virginica* in particular has been the subject of extensive studies covering every aspect of anatomy, physiology and ecology. All this, with everything relevant concerning *Ostrea edulis* and other species of 'flat' oysters, is here recounted. As Dr. Galtsoff states in his preface, it is written for the benefit of "biologists, administrators of oyster resources of various States, public health officers, students of marine biology and oyster growers", and thus he has been at great pains to "present the facts and discuss various theories in the simplest language". In this aim he has

\* United States Department of the Interior. *Fishery Bulletin of the Fish and Wildlife Service*, Vol. 64: *The American Oyster Crassostrea virginica Gmelin*. By Paul S. Galtsoff. Pp. 41 + 480. (Washington, D.C.: Government Printing Office, 1964.) 2.75 dollars.

been highly successful. This is an eminently readable as well as an exceptionally well-illustrated work.

The only criticism that strikes me in a book that has given me so much pleasure is some personal regret that Dr. Galtsoff has not apparently taken much note of recent work on the formation of the ligament—the inner layer being derived from the mantle isthmus (referred to as the ligamental ridge), and the outer layer from the outer fold of the mantle margin at either end. Surprisingly, he is also unable to find any clear reason for the presence of the promyal chamber which is one of the generic differences between *Crassostrea* and *Ostrea*. But surely this is a necessary consequence of the elongation characteristic of the former which involves a ventral-ward movement of the adductor and so restricts the exhalant region. This is certainly the case in the even more elongated *Mallois*, possibly the only other bivalve with a promyal chamber (personal, unpublished observation).

This account of the American oyster represents a major addition to the literature on the marine Bivalvia and so to marine biology. It is hard to see how it could have been done better and it only remains to congratulate and thank Dr. Galtsoff and all concerned with its production, not least the U.S. Department of the Interior which has given us so much for a mere 2.75 dollars. C. M. YONGE

## ANALYSIS OF QUEUEING AND RENEWAL WITHIN HUMAN SYSTEMS

By PROF. JOHN H. FRENSTER  
Rockefeller Institute, New York

THE analysis and integration of the diverse quantitative data of human physiology have been greatly facilitated by the recent development of such mathematical techniques as systems analysis<sup>1,2</sup>, control theory<sup>3,4</sup>, queueing theory<sup>5</sup>, and renewal theory<sup>6</sup>. Each of these techniques focuses on the abstract mathematical forms rather than the concrete physical features of the system under examination<sup>7</sup>. The aim of such analysis is the identification of the dependent and independent variables within a particular system, the determination of the quantitative relations between these variables, and the discovery of how such relations themselves change and are controlled during health and disease, rest and activity, hypertrophy and atrophy within individual patients.

For the purpose of analysis, a system may be defined as an integrated assembly of components which, by their interaction, effect some characteristic change on a substrate presented to them<sup>8</sup>. Implicit in this definition is the concept of a substrate flow of matter, energy or information first being presented to the system as an input load, then undergoing some characteristic transformation within the system, and finally emerging from the system as an output. Because of the flow or traffic characteristics of such substrates, they are recognized as throughputs, and the systems effecting their transformation as throughput systems<sup>9</sup>. Most, if not all, of the human systems of medical interest have been shown to be examples of throughput systems<sup>9</sup>, each with its own specific type of throughput units and with its own characteristic transformation of such units<sup>9</sup>.

In the identification of the variables within such human throughput systems, three general categories of independent variables have been recognized<sup>9</sup>. These are the input load of throughput units presented to the system for transformation, the available capacity of the system to effect transformation of these units, and the resistance opposing the exit of the transformed units from the system. By contrast, the output rate of transformed units from the system is a dependent variable, being determined by the interaction of the input load, the

system capacity, and the resistance to output from the system<sup>9</sup>.

Under pathological circumstances the system capacity may decrease or the input load or the resistance to output may increase<sup>10</sup>, so that the rate of arrival of throughput units into the system will exceed the rate of departure of transformed units from the system. In such a situation, the capacity of the system may become saturated and limiting, and waiting lines or pools of arriving throughput units may accumulate before the active service channels of the system (Fig. 1). This congested state of the system can be conveniently analysed by a deterministic form of queueing theory<sup>4,7</sup>.

The length in units ( $L$ ) of the waiting line formed in the buffer storage area of such a congested system is the sum of the initial waiting line-length ( $L_0$ ) and the integral of the difference in the rates of arrival ( $A$ ) and departure ( $D$ ) of throughput units from the system during the time-interval being examined.

$$L = L_0 + \int (A - D) dt$$

Fig. 1. Analytic model of queueing and renewal within human throughput systems. Throughput units awaiting transformation form waiting lines or pools before the service channels. An orderly and continuous turnover of service channels is mediated by a renewal mechanism which permits adaptive changes in the number of existing channels. Not all the existing channels need be in an active state nor be operating at a maximal rate of transformation per channel.

Within most human systems, a waiting line of some finite length exists in the normal state<sup>6</sup>. The presence of such a normal waiting line permits the smooth continuous flow of throughput units that is characteristic of these systems. In pathological circumstances, in which either system capacity is reduced or system input load or resistance to output is increased<sup>9,10</sup>, the length of the waiting line increases to exceed some value ( $L_{path}$ ) that is characteristic for each system, and which has been recognized statistically as a boundary value<sup>7</sup> correlating clinically with the transition from latent disease to overt disease<sup>8</sup>. Individual systems in which the length of the waiting line exceeds the value of  $L_{path}$  under basal conditions are recognized as being in a state of overt failure<sup>8</sup>. Conversely, systems in which the length of the waiting line under basal conditions is less than the value of  $L_{path}$  are recognized as being either in a state of health or in a state of latent failure<sup>8</sup>. The clinical use of load-tolerance tests<sup>11</sup> has been useful in distinguishing and quantitating these states in the health-disease continuum<sup>8</sup>.

If under basal conditions a test input load is administered to a particular system at a rate ( $A_{test}$ ) which is just sufficient to lengthen the existing waiting line length ( $L$ ) to the known boundary value ( $L_{path}$ ), and if  $D_{test}$  be the additional system output resulting from such a test load beyond that of the existing system output  $D$ , then:

$$\Delta L = L_{path} - L = \int (A_{test} - D_{test}) dt$$

where the magnitude of the test administration rate ( $A_{test}$ ) is a quantitative measure of the load-tolerance of the system at the existing levels of system capacity, input load, and resistance to output<sup>7</sup>. Such load-tolerance of a human throughput system is a dependent variable determined by the degree to which the available system capacity is in excess of that needed at the existing basal levels of input load and resistance to output<sup>8</sup>. In latent disease, the load-tolerance of the affected system is less than in the normal state, while in overt disease load-tolerance is reduced to zero and usually assumes a negative value<sup>7</sup>. A state of health within a particular system is thus characterized by a high load-tolerance within that system, and by measuring its load-tolerance, the magnitude of health or disease of a throughput system may be quantitatively determined<sup>8</sup>.

The capacity of a human throughput system is usually not constant, but rather is variable and responsive to the demands placed on the system<sup>9,12</sup>. Thus, pathological increases in the length of the system waiting line or decreases in the rate of system output often result in adaptive increases in the capacity of the system<sup>13</sup>. These throughput system changes are mediated by super-imposed control systems which continuously sample the throughput system waiting lines and output rates<sup>7</sup>, as well as communicate changes in other distant systems. Adaptive increases in system capacity are achieved by either an acceleration, an activation, or a hypertrophy of existing service capacity<sup>7</sup>. In the context of queuing

theory<sup>4,7</sup>, acceleration involves a decreased service time needed to effect a unit transformation within a service channel; activation involves a conversion of existing idle service channels to the active state; and hypertrophy involves a net increase in the total number of existing service channels (Fig. 1).

The service channels of nearly all human throughput systems are being constantly formed and broken down in an orderly turnover that can be conveniently analysed by renewal theory<sup>4</sup>. Hypertrophy of system capacity could be achieved during such channel turnover by either an increased rate of new channel formation or by a decreased rate of old channel breakdown. It is now evident that either or both of these renewal mechanisms are used by diverse human throughput systems in the adaptive hypertrophy of their system capacity<sup>13</sup>. The net increase ( $\Delta N$ ) in the number of service channels in such a hypertrophy response is a dependant variable determined by the rate of new channel formation ( $F$ ) and the rate of old channel breakdown ( $B$ ) within the system during the time-interval being examined:

$$\Delta N = \int (F - B) dt$$

Conversely, when system waiting lines decrease or when system output rates increase for a sustained period, these renewal mechanisms effect a corresponding atrophy of the system capacity, with  $\Delta N$  assuming negative values, the effect of such adaptive atrophy being to restore the balance between system capacity and the reduced demand placed on the system<sup>8</sup>.

Such adaptive changes within human throughput systems play a decisive part during the onset, course and therapy of many disease states<sup>8,14</sup>. A quantitative analysis of the queuing and renewal mechanisms which underlie these adaptive changes permits both greater insight<sup>13</sup> and more effective control<sup>11</sup> of these pathological states.

I thank Prof. Mark Kao and (the late) Prof. Norbert Wiener for their kind encouragement, and Dr. William R. Beet for his advice.

This work was carried out during the tenure of a research career development award (CA-17857) from the U.S. Public Health Service.

## GAS CLOUDS IN DENSE STAR CLUSTERS: A POSSIBLE QUASAR MODEL

By DR. A. G. W. CAMERON

Institute for Space Studies, Goddard Space Flight Center, National Aeronautics and Space Administration, New York

IN order to account for the large energy input required by intense extragalactic radio sources, I suggested that the collective formation of a cluster of more massive stars would result in numerous Type II supernova explosions in a limited period of time<sup>1</sup>. Following the discovery

of light flashes<sup>2</sup> in the light curve of the quasar 3C 273, S. A. Colgate and I adapted this picture also for quasars<sup>3</sup>, and proposed that the flashes resulted from the enhancement of the light output of the Type II supernovae when their ejected envelopes interacted with circumstellar gas

of density about  $10^{-18}$  g/cm<sup>3</sup>. Greenstein and Schmidt<sup>4</sup> then published their analysis of the emission lines from 3C 48 and 3C 273, from which they concluded that 3C 273 was a gas cloud of density  $\sim 10^{-17}$  g/cm<sup>3</sup> and dimensions  $\sim 1$  parsec which was held in place by a large unseen mass. It is the purpose of the present article to discuss more extensively the properties of such gas clouds in dense clusters of stars, and to see if the observed properties of quasars are compatible with them. The convention will be adopted that all the visible quasi-stellar objects<sup>5</sup> will be called quasars, and the intense radio-emitting objects will be called radio quasars.

Greenstein and Schmidt<sup>4</sup> have presented arguments based on line strengths to show that the electron temperature in 3C 48 and 3C 273 cannot be too large; their calculations were carried out with the assumption  $T_e = 1.68 \times 10^4$  °K. Oke<sup>6</sup> has given reasons for preferring a temperature about ten times as high as this; but he states that the lower temperature is not ruled out if much of the optical continuum emission is due to synchrotron radiation. In this discussion I shall follow the analysis of Greenstein and Schmidt with their lower temperature assumption.

The emission lines in 3C 48 and 3C 273 are very wide. If this is interpreted as resulting from a highly turbulent state of the gas, then the typical turbulent velocities in the two sources are 2,000 and 3,000 km/sec respectively. Consequently the turbulent motions are highly supersonic. Therefore shock phenomena must be widespread throughout the gas clouds and one would expect large fluctuations in the temperature. The single temperature assumption of Greenstein and Schmidt should therefore be regarded as giving results that can only be qualitatively correct.

It will be a crude but useful approximation to calculate the structure of a gas cloud with the assumption that it is in hydrostatic equilibrium in the gravitational potential well of a star cluster, but with the pressure being the turbulent pressure. I shall go further and assume that the turbulent motions scramble the lines of force of any initial magnetic field and build up the field strengths until there is approximate equipartition of energy between gas turbulence and turbulent magnetic fields. Then:

$$\frac{1}{2} \rho v_t^2 \sim \frac{B^2}{8\pi}$$

where  $\rho$  is the gas density and  $v_t$  is a typical turbulent velocity. The effective pressure is then taken to be:

$$P \sim \frac{1}{3} \rho v_t^2 + \frac{B^2}{8\pi} = \frac{5}{6} \rho v_t^2$$

The equations of hydrostatic equilibrium are:

$$\frac{dP}{dr} = - \frac{GM(r)\rho}{r^2}$$

$$\frac{dM(r)}{dr} = 4\pi r^2 \rho_s$$

Here  $\rho$  is the gas density and  $\rho_s$  is the matter density in stars, taken to be much greater than the gas density. I shall assume that the matter density in stars can be approximated near the centre of the cluster as uniform, independent of  $r$ . Therefore:

$$M(r) = \frac{4}{3} \pi \rho_s r^3$$

$$\rho = \rho_c \exp(-\alpha r^2)$$

$$\alpha = \frac{4\pi G \rho_s}{6 v_t^2}$$

Here  $\rho_c$  is the gas density at the centre of the cloud. The total mass of the gas cloud is:

$$M_g = (\pi/\alpha)^{3/2} \rho_c$$

The densities and dimensions of the gas cloud models for 3C 48 and 3C 273 can now be determined from the line emission strengths discussed by Greenstein and Schmidt<sup>4</sup>. In their approximations the volume emissivity of the H $\beta$  line is:

$$E(\text{H}\beta) = 3.0 \times 10^{-23} N_e^2 \text{ ergs/cm}^3 \text{ sec}$$

Here  $N_e$  is the electron number density which I may write:

$$N_e = N_0 \rho / \mu$$

where  $N_0$  is Avogadro's number and  $\mu$  is the mean molecular weight per electron (which I take to be 4/3). The total luminosity of H $\beta$  is then:

$$L(\text{H}\beta) = 1.09 \times 10^{43} \frac{\rho_c^2}{\mu^2} \left( \frac{\pi}{2\alpha} \right)^{3/2}$$

Similarly, for  $N_e \gg 10^4$  cm<sup>-3</sup>, the emissivity of the forbidden lines of O II is:

$$E(\text{O II}) = 3.42 \times 10^{-31} N_e$$

and the total luminosity is:

$$L(\text{O II}) = 2.06 \times 10^{43} \frac{\rho_c}{\mu} \left( \frac{\pi}{2\alpha} \right)^{3/2}$$

The forbidden lines of O III yield similar relations:

$$E(\text{O III}) = 2.16 \times 10^{-18} N_e$$

$$L(\text{O III}) = 1.30 \times 10^{43} \frac{\rho_c}{\mu} \left( \frac{\pi}{2\alpha} \right)^{3/2}$$

Greenstein and Schmidt modified these expressions to match relative line strengths in planetary nebulae. However, it is evident that the excitation conditions are quite unlike those encountered in planetary nebulae, so the modifications of Greenstein and Schmidt have not been used here.

For 3C 273,  $L(\text{H}\beta) = 8.8 \times 10^{43}$  ergs/sec and  $L(\text{O III}) = 3.1 \times 10^{43}$  ergs/sec. From these one obtains the formal solution:

$$\rho_c = 1.28 \times 10^{-18} \text{ g/cm}^3$$

$$\alpha = 3.69 \times 10^{-17} \text{ cm}^{-2}$$

Thus in this solution the gas densities come out significantly higher than in the consideration of Greenstein and Schmidt, and the range of densities is quite consistent with that required for the enhancement of light flashes<sup>8</sup>. The characteristic radial distance in the gas cloud is:

$$\alpha^{-1/2} = 1.65 \times 10^{17} \text{ cm}$$

This distance is about 0.05 parsecs.

The turbulent magnetic field in 3C 273 is given by:

$$B \leq (4\pi \rho_c)^{1/2} v_t = 38 \text{ gauss}$$

This magnetic field will stiffen the gas very much against supersonic compression. Consequently the possibility exists that the gas cloud can undergo a radial vibration through the medium of this magnetic field. The characteristic period  $\tau$  of this vibration would be roughly the characteristic radial distance divided by the Alfvén velocity. The Alfvén velocity is:

$$v_A = B/(4\pi \rho)^{1/2} \sim v_t$$

Hence  $\tau \sim \alpha^{-1/2}/v_t = 17$  years. This value of the period is remarkably close to the observed period<sup>9</sup> of 13 years for the general variability of the light curve.

However, it is not sufficient that there should be radial vibration in order to produce a variation in optical emission. The cloud is transparent at optical wave-lengths and the recombination times are orders of magnitude less than the vibration period. Consequently the heating mechanism should also depend on the density of the gas.

The total mass  $M_g$  of the gas cloud is  $1.6 \times 10^4 M_\odot$ . The stellar density is:

$$\rho_s = 5\alpha v^2 / 4\pi G = 2 \times 10^{-11} \text{ g/cm}^3 \\ = 2.9 \times 10^{11} M_\odot / \text{pc}^3$$

This is an exceptionally high density of stars. We do not know the total mass of stars, but if the foregoing density extends out to 0.1 parsec, twice the characteristic radial distance, then a star cluster of  $10^4$ – $10^5 M_\odot$  would be involved. Many people would prefer to call an isolated star cluster of this mass a small galaxy.

For 3C 48,  $L(\text{H}\beta) \approx 6.4 \times 10^{43}$  ergs/sec and  $L(\text{O II}) = 3.3 \times 10^{43}$  ergs/sec. The formal solution of the equations then gives:

$$\rho_s = 1.38 \times 10^{-18} \text{ g/cm}^3 \\ \alpha = 2.36 \times 10^{-3} \text{ cm}^{-1} \\ \alpha^{-1/2} = 6.5 \times 10^{18} \text{ cm} \approx 2 \text{ parsecs} \\ B < 0.83 \text{ gauss} \\ M_g = 1.06 \times 10^4 M_\odot \\ \rho_s = 5.6 \times 10^{-18} \text{ g/cm}^3 = 8.3 \times 10^7 M_\odot / \text{pc}^3$$

In this case the star density is more normal, but there are already  $3 \times 10^8 M_\odot$  within the characteristic radial distance and  $2 \times 10^{10} M_\odot$  within twice that distance. Consequently there is definitely a mass of galactic order associated with the gas cloud in 3C 48.

We now consider sources of energy for heating these gas clouds. Such energy must be available in a form which continually imparts supersonic velocities to the quasar gas. Three possible energy sources may be considered: (1) supernova explosions; (2) stellar collisions; (3) interaction between stars and gas.

Supernova explosions of Type II eject envelopes containing several solar masses and  $10^{44}$ – $10^{45}$  ergs of kinetic energy<sup>1,2</sup>. These envelopes will impart supersonic motions to the gas with which they interact. The characteristic interaction time will be  $\sim 10^3$  years for 3C 48. The rate of occurrence of supernovas depends on the mass distribution of the stars and whether or not they were formed concurrently. With a collective stellar formation process there will be a period of  $10^4$  or  $10^5$  years in which there may be several supernova explosions per year in a cluster with  $10^8 M_\odot$  and a reasonable mass distribution. This would give an energy input of  $10^{44}$ – $10^{45}$  ergs/sec, which is in the quasar range of energy emission.

An energy source from stellar collisions has been suggested by Gold, Axford and Ray<sup>3</sup>. For simplicity consider that all stars in the cluster of radius  $R$  have the same mass  $M_s$  and radius  $R_s$ . Then the number of collisions per sec is:

$$N = \frac{1}{2} \frac{\rho_s^2}{M_s^2} (\pi R_s^2) v_s \left( \frac{4}{3} \pi R^3 \right)$$

Here  $v_s$  is the typical stellar velocity, which I take also to be a typical relative collision velocity. From the virial theorem I find:

$$v_s = \left[ \frac{9G\rho_s}{20\pi} \right]^{1/2} R \\ N = 6.4 \times 10^{-4} \frac{\rho_s^{3/2} R_s^2 R^4}{M_s^2}$$

For purposes of illustration let us take  $M_s = 2 \times 10^{34}$  g and  $R_s = 10^{12}$  cm, corresponding to  $10 M_\odot$  stars. For 3C 273 we also take  $R = 3 \times 10^{18}$  cm. Hence  $N = 2.3 \times 10^{-1} \text{ sec}^{-1}$ . However, only about  $10^{-3}$  of these collisions take place in the quasar gas. The stellar velocity is  $1.3 \times 10^8$  cm/sec ( $R$  was chosen sufficiently large that  $v_s$  would be significantly greater than the turbulent velocities of  $3 \times 10^8$  cm/sec). This velocity is supersonic with respect to the interior stellar thermal velocities, but most collisions will be non-central. Thus a few per

cent of stellar kinetic energies may be ejected as gas in each collision. Hence, within the quasar gas there is likely to be an energy input of  $10^{44}$ – $10^{45}$  ergs/sec. However, if  $R = 3 \times 10^{17}$  cm, the collision rate and stellar velocities each drop a factor 10 in the quasar gas, so that the energy input would drop by a factor  $10^3$ . Collisions would then supply only a small part of the energy output of 3C 273.

It is evident that collisions will not be important in 3C 48.

From the foregoing illustration it is evident that the stars will pass with supersonic motion through the gas. Hence, as in the case of the Earth in the solar wind, bow shocks will stand off in front of the stars. For simplicity we may make the rough estimate that the gas will be accelerated to the stellar velocity out to about two stellar radii, and the gas within one stellar radius will be accumulated by the star. The energy given to the gas per second per star is then:

$$\frac{3}{2} \pi \rho_s R_s^2 v_s^3$$

In 3C 273, with  $R = 3 \times 10^{18}$  cm, this imparts to the gas about  $10^{37}$  ergs/sec per star, or about  $3 \times 10^{44}$  ergs/sec in the quasar gas. The energy input to 3C 48 would be considerably less. While this mechanism seems unlikely to be providing the energy input for these radio quasars, it might readily suffice for ordinary quasars which probably have somewhat smaller total luminosities.

While the two quasar models discussed here are transparent in the optical region, they are opaque to free-free absorption in the radio region. Hence, the flat radio emission spectrum must be emitted from outside the quasar gas region. However, Dent<sup>10</sup> has found that the 8,000 Mc/s flux from 3C 273B is variable and must be emitted from a region of only a few parsecs dimension. Hoyle and Burbidge<sup>11</sup> have discussed a synchrotron emission model in which this is possible; their magnetic fields and particle energy distributions are consistent with the model of the 3C 273 gas discussed here.

Sandage<sup>8</sup> has noted that ordinary quasars are much more abundant than radio quasars and may be somewhat less luminous. If we assume that the radio quasars are powered by supernova explosions, then this situation can be understood in terms of the preceding energy discussion. In this picture energetic particles are created in the supernova explosions and provide radio emission in the magnetic field system surrounding the quasar. But after supernova activity dies out, star-gas interactions will continue to power the denser quasars for optical emission. The less-dense quasars would become very dim but would brighten when a supernova explodes. This may have happened in 3C 2 (ref. 12). However, on this picture the total optical emission lifetime of denser quasars may be considerably longer than has been suspected.

As Oke<sup>9</sup> has noted, much of the optical continuum radiation from 3C 273 may be synchrotron emission. This would lend support to the idea that it is mainly powered by supernova explosions. At the same time, variations in the light output would accompany radial oscillations owing to the variation in magnetic field strengths.

# GEOLOGICAL HISTORY OF THE SLIEVE GAMPH MOUNTAINS, WESTERN IRELAND

By DR. A. E. CURRALL and W. E. G. TAYLOR

Department of Geology, University of Sheffield

WORK now in progress into the structural and metamorphic history of the southern or Slieve Gamph part of the Ox Mountains in Counties Sligo and Mayo has yielded important information bearing on the Caledonides of Ireland. This article contains a preliminary account of these results which help to present a more complete picture of the structural and metamorphic phases operative during the Caledonian orogeny.

The area under discussion lies between Lough Eskey to the north-east and Pontoon at the southern end of Lough Conn to the south-west. The early work of R. G. Symes<sup>1,2</sup> showed the presence of a central body of granitic gneiss extending along the length of Slieve Gamph as far as Lough Talt and bounded on the north-west and south-east sides by metamorphosed sediments. In the Pontoon area Symes recognized that while the normal granite was greyish there was a distinct pink to red coloration which could be correlated with faulting. M'Henry<sup>3</sup> recognized a succession of quartzite, conglomerate, limestone, shales or schists and pebbly grits. The pebbly grits he correlated with beds of similar lithology 10 miles to the west at Westport. He further recognized that the granitic core of Slieve Gamph had invaded an earlier basic intrusion and had itself been affected by "intense Earth stresses which resulted in a milling out, shearing and banding of all three varieties of rock". The age of injection of the granitic material was regarded as early Devonian on the basis that the metamorphosed sediments were Ordovician or early Silurian in age. M'Henry's contribution to the knowledge of Caledonide geology is important in that he was one of the first workers to recognize that its metamorphic history was polyphase.

**Regional setting.** A typical Upper Dalradian sequence has been thrust over both the Slieve Gamph pluton and its meta-sedimentary envelope from the north-west, in a series of thrust slices (Conloon and Sheeans Thrusts) separated by a marked imbricate zone. Between the Conloon Thrust and the Sole Thrust a further imbricate zone involves the Slieve Gamph pluton and its envelope. The dating of these thrust movements as post- $F_1$  and pre- $F_2$  is based on the divergence and lack of correlation of  $F_1$  and  $F_2$  structures between the thrust slices and the fact that  $F_1$  structures may be traced directly across the whole area without any breaks at the thrust planes.

Coarse current bedded sandstones, conglomerates and green silts which in part can be shown to be thrust over the Dalradian at the south-west end may on the basis of somewhat poorly preserved spore material be in part Middle Old Red Sandstone<sup>4</sup>. Visean Carboniferous sediments overstep on to all these older rocks and at some stage have probably covered the whole of the Ox Mountains<sup>4</sup>.

**Sequence of events in the Slieve Gamph igneous complex and its envelope.** Four

distinct lithological types are found within the complex (Fig. 1):

- Trondjemite ( $D$ ).
- Porphyritic granodiorite ( $G_1$ ).
- Biotite adamellite ( $G_2$ ).
- Micrographic granite veins ( $G_3$ ).

Sharp contacts have been observed between  $D$  and  $G_1$ ,  $G_1$  and  $G_2$ , and also between veins of fine-grained  $G_2$  and  $G_1$ . A contact between  $G_2$  and  $G_3$  has not been found due to poor exposures in the critical localities. A small boss of  $G_3$  is exposed some 5 miles to the north-east of Lough Talt at Lough Eskey and it is considered probable that the exposed areas of  $G_2$  represent part of a larger igneous body at depth.

The following structural and metamorphic sequence of events has been deduced.

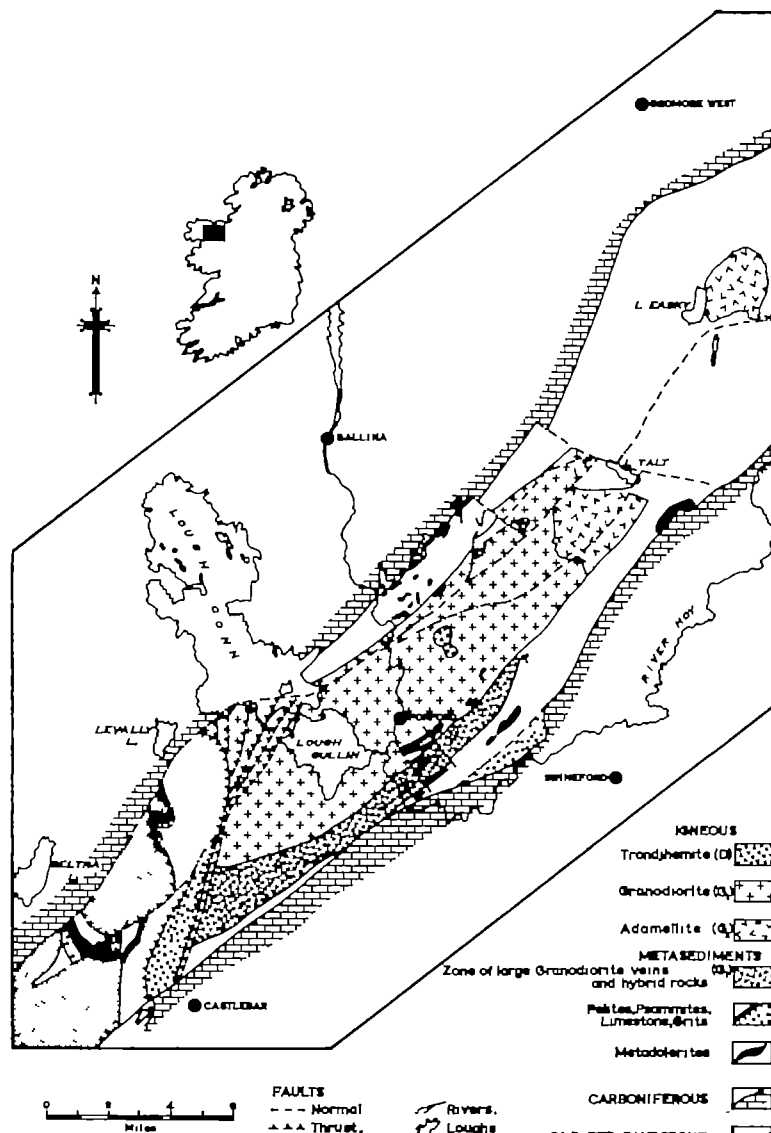

Fig. 1. Geological map of the Central and South-west parts of the Ox Mountains, Co. Mayo, Eire

(1) Deposition of the sediments of the envelope, probably Dalradian.

(2) Intrusion of a suite of basic sills and dykes.

(3)  $F_1$  movements. Folding occurred on a large recumbent scale and was associated with sliding which is well exposed to the south-west of Lough Talt. In this area part of the overturned limb of a large recumbent fold trending east-west and probably closing towards the north is present. Biotite appears to be the only new mineral developed during this phase.

(4) There then followed a period of static metamorphism in which garnet was developed which often shows trails of the  $F_1$  fabric. Felspathization occurred with the development of oligoclase and local migmatization.

(5)  $F_2$  movements. The  $F_2$  folds are tight with a steep axial plane trending between  $040^\circ$  and  $070^\circ$ . A strong penetrative axial planar foliation due to the growth of muscovite and a prominent lineation is developed. The  $F_2$  tectonic slides of the Lough Talt area were folded. The post- $F_1$  static growth of garnet was continued during this phase with the development of synkinematic overgrowths on the earlier crystals. At some stage of the deformation splite and pegmatite veins were intruded. It has not been possible to ascertain their exact time position.

(6) The  $F_2$  folding was followed by a second period of static metamorphism during which the most prominent minerals formed were staurolite, garnet and tourmaline.

(7) *Intrusive phase.* This phase in the history of this area started with emplacement of a trondjemite (D) and the main parts of which now exposed lie north-east of Foxford. The evidence leading to this position is twofold: firstly the trondjemite may be seen to cross-cut the  $F_1$  folds, and secondly both the trondjemite and the granodiorite ( $G_1$ ) are in places affected by all subsequent movement phases. The emplacement of (D) was followed fairly closely by that of the main mass of granodiorite ( $G_1$ ).

(8) Subsequent plastic deformation of D and  $G_1$  produced a shear foliation (trending  $050^\circ$ ) and a lineation. It is considered that these structures are associated with the intrusion of the Adamellite ( $G_2$ ) and that the whole intrusive complex and the envelope moved upwards as one plastic unit, but that the igneous rocks were in the more plastic condition. Evidence of this movement is to be found particularly on the southern side where  $F_2$  fold limbs are often partially sheared. There is also an extensive development of 'pull-apart' structures and pseudo boudins (Fig. 2).

*Contact metamorphism of the envelope by  $G_1$  and  $G_2$ .* It is difficult to separate the contact effects of either the  $G_1$  or  $G_2$  igneous phases from the slightly earlier static regional metamorphism. The extent of the aureole is generally about a quarter of a mile from the contact but widens towards the south-west where a series of large  $G_1$  veins invade the country rock of the envelope. To the north the contact zone is cut out because of later ( $F_2$ ) faulting. Within the zone biotite is replaced by fibrolite, and staurolite is altered to a micaceous mass which in places has gone to fibrolite and iron ore. The biotite of the country rocks also becomes increasingly foxy-brown in colour towards the contact, and flakes of muscovite have grown at random across the early schistosity. Near Foxford and around Pontoon a series of pink microcline pods are found in the metasedimentary enclaves and the nearby  $G_1$ —this is thought to be due to a late stage potash metasomatism connected with the igneous intrusion and predating the late plastic movements.

(9)  $F_3$  movements. The  $F_3$  folds occur as a series of kink bands and close, often tight, folds trending between  $000^\circ$  and  $050^\circ$ , with a strain slip cleavage. There was little new mineral development at this stage apart from a phase of retrogressive metamorphism affecting garnet and tourmaline, both of which have been altered to chlorite. Mesocrenulations corresponding to  $F_3$  can be traced right across the igneous complex.

The probable culmination of the  $F_3$  movements was large-scale major thrusting from a north-westerly direc-

Fig. 2. 'Pull-apart' structures in metasediments. Diagrams A-E show the variations of lithology associated with these structures. Note the constancy of the angle of the surface of disruption.

tion, which brought the typical upper Dalradian sequences of the Croaghmoyle Hills (south-west Ox Mountains) into their present position\*. It was a deep-seated movement bringing up serpentine along parts of the thrust planes, particularly just north of Castlebar.

(10)  $F_4$  movements. The  $F_4$  folds are represented as a series of small kink bands and crenulations which trend between  $140^\circ$  and  $180^\circ$ . The style of folding varies from open to close and in places the intersection of  $S_3$  and  $S_4$  (that is, the axial surfaces of the  $F_2$  and  $F_3$  folds) have produced meso-scale conjugate folds with a gentle plunge towards the north-east. On the larger scale the strike of the  $F_2$  folds are rotated through approximately  $20^\circ$  (that is,  $050^\circ$ – $070^\circ$ ) in the Lough Talt area, and very open folds are found.

(11) A minor phase consisting of an emplacement of a series of pegmatites and aplites.

(12)  $F_5$  movements. The  $F_5$  folds are a poorly developed series of kink folds trending roughly north-south with a vertical plunge.

(13)  $F_6$  movements. These late movements consist of an earlier thrust fault followed by north-east to south-west trending faults (? normal) which have displaced the outcrop of the igneous complex. Small drag folds are associated with both sets of faults. It is probable that the movement history of these faults was extremely long and complex, particularly in the case of the Lough Conn Fault which separates Old Red Sandstone and metamorphic rocks on the south side from Carboniferous on the north side. They were probably initiated in Devonian times and extended well into Carboniferous times—when they had a pronounced effect on sedimentation. For example, in Glen Hest and Glen Nephin immediately to the north-west of the Lough Conn Fault at least 1,500–2,000 ft. of Carboniferous conglomerates and sandstones occur against the fault. Four miles to the north-west on the other side of the glens the maximum thickness resting unconformably on the Dalradian of Nephin is 100–150 ft., while on the southern margin of the metamorphic area less than 50 ft. are to be found near Castlebar.

# LOWER CRETACEOUS FLUVIATITES IN THE LEVANT

By DR. IAAKOV KARCZ  
Geological Survey of Israel, Jerusalem

THE occurrence of a clastic series, varying in thickness, at the base of the Lower Cretaceous succession in the Levant has been known for a long time. These predominantly sandy strata, unconformably overlying the Jurassic and occasionally even older formations, extend from Sir in northern Lebanon<sup>1-3</sup> southwards, through Israel<sup>7-10</sup> and Jordan<sup>11-14</sup>, to Sinai and Egypt.

In Israel the Lower Cretaceous formations crop out in many localities, nearly always along the cores of folds and along tilted-block structures. In the south the entire section is exposed and consists mainly of variegated sandstones of the so-called 'Nubian facies'<sup>15</sup>. In central and northern Israel, it is mainly the upper part of the Lower Cretaceous, usually calcareous and shaly, which is exposed. The lower, Nubian facies sandy series appear here at two localities only, Rami and Qiryat Shemona (Galilee).

The distribution of the Lower Cretaceous strata reported from Jordan (*op. cit.*) follows a very similar pattern. In the Lebanon and Anti-Lebanon mountains of Lebanon and Syria, where the intensity of folding is greater than in Israel and Jordan, the Lower Cretaceous is fully exposed in many areas. The stratigraphical section is very similar to that exposed in north of Israel and Jordan and consists of an upper, calcareous and marly part (Albian-Aptian) and a lower sandy group, the so-called 'Grés de base' (*op. cit.*) (Neocomian?). Some of the previous investigators assumed that the Grés de base formed in an estuarine environment, while many others believed them to be of an aeolian origin.

The examination of the sedimentary structures exposed within the sandstone quarries of Qiryat Shemona indicated that the Lower Cretaceous clastics were deposited in shallow water, probably less than 10 m deep, stirred by currents flowing to the north-north-west.

The strata are heavily cross-bedded (60-80 per cent). The sets are nearly always plane parallel or sub-parallel and are grouped in thick co-sets (Fig. 1). The basal surfaces show slight erosional irregularities. The sets vary in thickness from 8 to 50 cm. The inclination of the layers is

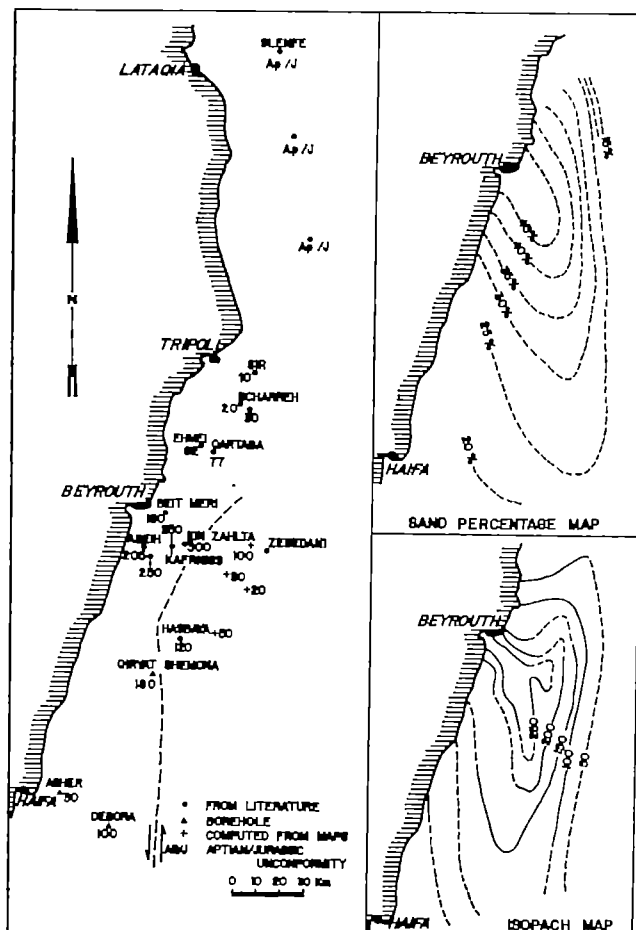

Fig. 2. Distribution of the Lower Cretaceous sandstones in the Levant (Karcz, Golan, 1964)

moderate to strong. After the removal of tectonic tilt (usually between 10° and 20°), about 50 per cent of the cross-sets show dips exceeding 20° and approximately 10 per cent show dips exceeding 30°.

Though in most cases the cross-bedding is tabular, some trough-sets are occasionally encountered. These sets are inclined to each other (15°-20°); the layers are strongly concave and approach the spoon shape. The contacts are strongly erosive.

The cross-bedding is accompanied by numerous occurrences of ripple-drift and graded bedding. The ripples are 1-2 cm high, with ripple index of 0.5-0.5. They are notably asymmetric to the north (index 1.6-2.1). In places a gradual transition from the ripple-drift régime to that of cross-bedding may be observed. The occasional rather irregular lenses and bands of shale with plant remains result either from fluctuations in flow velocity or result from sediment-transport lag.

The current directions as indicated by the re-tilted cross-bedding dips and by the ripple-drift point north-north-westwards (Fig. 1). Twenty per cent of the current-azimuths point between 320° and 340°, 20 per cent between 340° and 000°, and a further 30 per cent point between 000° and 020°.

The Qiryat Shemona and Rami exposures represent but a very small fraction of the Lower Cretaceous outcrops in the northern Levant, but, since no other detailed litho-

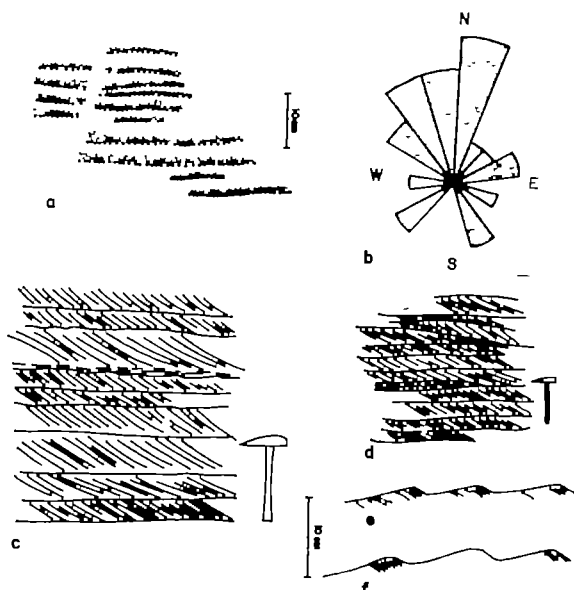

Fig. 1. Sedimentary structures in the Grés de base. a, Repeated graded bedding; b, orientation of the palaeocurrents (equal area rose diagram); c and d, cross-stratification; e and f, ripple-profiles

structural information from the adjoining countries has ever been published, I feel that a brief discussion of the possible palaeogeographical significance of the results is justified.

Fig. 2 shows the thicknesses of the Grés de base compiled from various sources. Though the information is incomplete and the stratigraphic correlations postulated by the various investigators are often tentative and somewhat ambiguous, yet the data are sufficient to present a general picture of the distribution of sands. Accordingly with the strike-slip theory of the Jordan Rift origin<sup>14-19</sup> all the points on the map, located east of the rift, were shifted 70-75 km southwards and then isopachs were drawn.

Fig. 2 suggests that we are dealing with a channel or river-like elongated area of sand deposition with a north-north-west direction of transport. The Beyrouth area, where the amount of sand is the highest, may represent an area closer to the river-mouth. It may also, however, represent an accumulation of sand close to a river-bend or close to a junction of two or more streams.

It is highly probable that, in the Beyrouth area, the north-north-west-oriented palaeocurrent pattern gives place to a more westwardly oriented one. North of Beyrouth the currents probably flowed to the south and south-west.

The Lower Cretaceous sandstones of central and southern Israel and Jordan are believed to belong to a different area of sand deposition.

It should be stressed that the picture presented in the maps of Fig. 2 may be misleading:

(a) The Lower Cretaceous clastics overlie unconformably the older strata.

(b) The absence of sand north of Tripoli, where the Aptian marls and limestones overlie the Jurassic, may be due to truncation or sedimentation-break, as opposed to the thinning out of the sands on the south and west, where they are replaced by shale, volcanics and limestones.

(c) A faulting phase is known to have occurred in the late Jurassic times. It is possible, therefore, that the sandstones were laid on a pre-existing block relief.

However, it should be obvious that the palaeogeographical picture suggested here is intended only as a temporary working hypothesis.

It is hoped that this hypothesis will be checked and re-examined by geologists working in Lebanon and Syria, whose results, when published, will make further correlations possible.

## THE OMEGATRON: A USEFUL TOOL FOR ARGON ISOTOPE INVESTIGATION

By DR. R. L. GRASTY and DR. J. A. MILLER

Department of Geodesy and Geophysics, University of Cambridge

POTASSIUM-ARGON age measurements on young rock samples depend on the accurate determination of the extremely small volumes of argon-40 which are trapped in the rock. This radiogenic argon-40, evolved from the decay of radioactive potassium-40, is usually measured using the conventional 90° or 120° direct focusing type of mass spectrometer. We have recently constructed and used successfully an omegatron, a mass spectrometer of high sensitivity and low-background noise which works on the cyclotron principle and is ideally suited for this particular work.

The omegatron device was first described by Sommer *et al.*<sup>1</sup> and later modified by Alpert and Buritz<sup>2</sup> to give a simpler design. The omegatron head being used in the work recorded here is one designed by Philips, Ltd., Aachen, for use in measuring partial pressures (Fig. 1). Ions formed in a magnetic field by electron bombardment will describe circles the natural frequency of revolution

of which is given by the cyclotron frequency. A radio-frequency field applied perpendicularly to the magnetic field will accelerate ions with this same frequency of oscillation and their path will become an Archimedes spiral. These resonant ions can be trapped by a suitably placed collector and detected by a sensitive amplifier. Non-resonant ions describe spiral paths with pulsing radii and do not reach the collector.

The theory of an idealized omegatron (neglecting electrostatic fields and space charge effects) was formulated by Sommer *et al.*<sup>1</sup>, who gave the expressions for resolving power, time of flight, path length and final energy of the ions. In an idealized omegatron no electric fields exist and the collection of the resonant ions is complete, but in a real omegatron of the type described by Alpert and Buritz there are always fields present which can cause some of the resonant ions to be lost. These fields are caused by: (a) space charge effects due to the electron beam and the ions present; (b) the electrodes of the omegatron which can become charged; (c) leakage fields from the accelerating plates; (d) the small positive field which must be applied to prevent drift of the ions in the direction of the magnetic field.

These fields can be of the same order of magnitude as the applied electric field and hence large variations in the ion collection can result. The Philips head is identical to that designed by Sommer *et al.* when viewed in a direction perpendicular to the magnetic field (Fig. 1), but in addition it has two side plates CC' to which a large negative voltage can be applied. This negative voltage extracts non-resonant ions, reducing the space charge effects, and together with the RF voltage can be adjusted to obtain a complete collection of resonant ions<sup>3</sup>, and give the tube a reproducible sensitivity. The value of this voltage

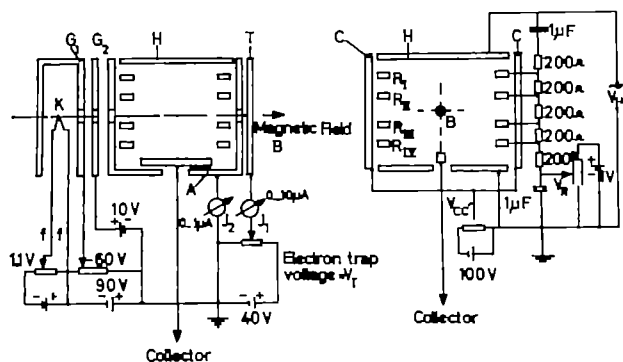

Fig. 1. Schematic diagram of the omegatron.

depends on the number of guard rings used to keep the RF field uniform and the positive voltage,  $V_R$ , which prevents the drift of ions in the direction of the magnetic field. The electrode assembly forms a cube of side about 2.5 cm and is arranged with the electrodes as in Fig. 1.  $J_s$  is a sensitive meter used in the setting up procedure and  $H$  the plate to which the RF voltage is applied. An account of the operating characteristics have been described by Krummenacher<sup>4</sup>. The whole assembly can be degassed to 400° C and the metal electrodes to 900° C by induction heating if need be. Using Balzer's ultra high vacuum pumping equipment an overnight bake at a temperature of 200° C is found quite sufficient to obtain a pressure reading in the range of  $1-2 \times 10^{-10}$  mm of mercury. At this pressure the only significant peaks observed are those at masses 28 and 44.

The voltages to the electrodes are provided from a stabilized supply and the emission regulated in the normal way using the feedback from the trap as a control.

An all-metal argon purification line similar in construction to that described by Miller<sup>5</sup> (Fig. 2), but with several modifications, is connected via a metal tap directly to the omegatron. An automatic loader was devised whereby several samples can be loaded at once. These samples rest on stainless steel rods, which can be withdrawn with a magnet into short side-arms, allowing the samples to drop in the metal fusion crucible. With this technique the atmospheric contamination due to air adsorbed on to the crucible and quartz support can be largely removed, and the contamination due to that on the sample greatly reduced. This automatic loading device is particularly useful for whole-rock measurements, but can also be adapted for separated minerals by making small glass phials to contain the samples. It also has the advantage that the system need not be opened between measurements, thus reducing the atmospheric argon content of the final gas sample and making determinations easier and quicker.

The gas sample obtained from the rock mixed with a sample of enriched argon-38 (the 'spike') of known volume is prepared for admission to the head as described by Miller and Brown<sup>6</sup>. As an extremely low emission

Fig. 2

Fig. 3. A typical scan obtained by manual adjustment of the controls

current is used (1-3  $\mu$ amp) and the gas evolution of the apparatus can be made small, no significant change in pressure occurs over a period of several hours, after the gas sample has been admitted and the tap to the pumps closed. Hence the static method of analysis can be used in which the gas sample is isolated from the pumps and the appropriate masses scanned with their peak heights remaining constant. This produces a great increase in sensitivity over the more usual dynamical method where the gas sample is drawn into the mass spectrometer through a tap with a small leak, isotopic fractionation occurring, and the original composition of the sample determined by extrapolating back to the time the tap was opened.

The peaks can be scanned either automatically or manually. Using the static method, manual scanning was found to be preferable to automatic scanning as the peaks were quite stable in the resonance condition and could be measured for a considerable time, reducing any errors caused by fluctuations in the emission, due to mains transients. The resonant peaks can be located by adjustment of the oscillator frequency or the magnetic field. After some experiments it was found that the numbered scale of the dial on the electro-magnetic control could be used as a setting for the different masses and provided a more sensitive adjustment. Fig. 3 shows a typical scan using a field of approximately 9 kilogauss and a fixed frequency of 350 kc/s. The peaks remain constant in height even after a period of several hours. We have also found that the response of the machine is linear with the size of the argon sample provided the pressure does not exceed  $2 \times 10^{-8}$  mm of mercury.

It has frequently been reported that with a Reynolds type of machine the sample being analysed can become contaminated with the previous sample. Reynolds<sup>7</sup> suggested that ions could be driven into the walls of the tube and cause this memory effect. We have not experienced this difficulty, presumably because complete collection of resonant ions is achieved and hence none of the ions can reach the walls. In fact, the sample can be completely pumped away and the background restored to its original state in a few minutes.

As previously described, the voltages can be adjusted to give a complete collection of resonant ions. This resonant ion current is not critically dependent on these voltages provided the RF voltage is high enough for all resonant ions to reach the collector, and hence the isotope ratios obtained remain constant unless a large variation in  $V_{CC'}$  or  $V_R$  occurs. This is a great advantage over the 180° type of machine in which the ratios are normally critically dependent on the applied voltages<sup>8</sup>, and the 90° or 120° type where fringing magnetic fields cause non-ideal conditions in the source. Figs. 4 and 5 show the working ranges of  $V_{CC'}$  and  $V_R$  for resonant ions of argon-38. It is interesting to note that for values of  $V_R$  between 0.2 and 0.5 V non-resonant and resonant ions can be collected, for it is a property of an omegatron that total ion current can be measured in the absence of an RF field. This occurs when the potential of the ion source becomes equal to the potential of the ion collector due to space charge effects.

The omegatron has no mass discrimination effects when adjusted correctly because complete collection of resonant ions is achieved. We have carried out many determinations of the atmospheric argon isotope ratios and have obtained values of:

$$^{40}\text{Ar}/^{36}\text{Ar} = 295.6 \pm 1.5$$

$$^{36}\text{Ar}/^{38}\text{Ar} = 5.26 \pm 0.06$$

This agrees very favourably with the results obtained by Nier<sup>1</sup>, whose values were  $296.0 \pm 0.53$  and  $5.32 \pm 0.01$  respectively.

For argon isotope work it is essential that the 40, 38 and 36 peaks are completely resolved. Sommer *et al* have shown that for an idealized omegatron of similar size to ours, complete separation of one mass unit at mass 40 should be achieved. In the instance of the Cambridge

Fig. 4. Resonant ions of argon-38

Fig. 5. Resonant ions of argon-38

Fig. 6. Resolution scan of atmospheric argon mixed with 'spike' argon

omegatron, complete separation of one mass unit would appear only to be possible up to mass 30; however, the tailing of the 38 on the 36 peak is less than 1 part in 50,000 and completely undetectable. A typical scan of atmospheric argon mixed with 'spike' 38 clearly shows the complete separation of the three isotopes (Fig. 6).

The sensitivity clearly depends on the volume of apparatus and was not adjusted to a maximum as excessive sensitivity would be a disadvantage in dealing with the rocks at present under investigation. In our present system a gas sample of  $10^{-10}$  c.c. N.T.P. when let into the head from the last section of the argon-line will produce an ion current of  $1 \times 10^{-10}$  amperes. Using a  $10^{10}$  ohm input resistor in the vibron head of the amplifier this represents a voltage drop of 1 V at unit gain of the amplifier. At maximum gain 0.1 mV is easily detectable against the random background noise level and consequently it is possible to detect a volume of  $10^{-10}$  c.c. N.T.P. with the omegatron adjusted in its present condition. This is comparable, if not better, than the sensitivity achieved by other machines using an emission current that is at least 10 times as large.

The omegatron is not only an elegant and efficient mass spectrometer but has also been shown to be ideally suited for argon isotope work. It has several important advantages over the conventional machine, having no mass discrimination, a linear response, and being highly sensitive. With the low-emission currents used and the small volume of the detector head, pumping down time is rapid and the low ultimate pressures obtained can be maintained for long periods when the system is isolated from the pumps. It is also cheap and straightforward to operate and could prove invaluable to a research department interested in potassium-argon work at low ages.

We thank Dr. A. Klopfer of Philips in Aachen, Dr. R. H. Bieri of the University of Berne, and Mr. L. H. Flavill and Mr. K. Plachecki of the Department of Geophysics, Cambridge, for their advice and assistance. This work was supported by the Department of Scientific and Industrial Research.

# ANAESTHESIA AND TEMPERATURE EFFECT MECHANISM IN NEUROMUSCULAR BLOCKING BY N<sup>+</sup> QUATERNARY DEPOLARIZING DRUGS

By Dr F. G. CANEPA

Department of Physics, Northern Polytechnic, London, N.7

It has been shown that the lowering of the muscle temperature in animals increases the magnitude and duration of the action of depolarizing neuromuscular drugs<sup>1</sup> such as decamethonium (DM) and succinylcholine (SM). This is related during anaesthesia to the interactions between acetylcholine (ACh) and the aforementioned drugs. A similar variation occurs in human beings, where a fourfold increase of the blocking activity of DM is observed at the moment of maximum activity, when a temperature lowering of about 4° C is used<sup>2</sup>.

The time necessary for the action of tetramethylammonium (TMA) on nerve-sartorius preparations<sup>3</sup> was found to increase by a factor of 1.5 for 10° C of cooling. Ing and Wright<sup>4</sup> have pointed out that "if the Arrhenius formula:

$$v_2 = v_1 \exp(\mu(T_2 - T_1)/2T_2T_1)$$

is assumed, where  $v_1$ ,  $v_2$  are velocities at temperatures  $T_1$ ,  $T_2$  degrees absolute respectively,  $\mu$  will have the values of 6426 and 7336 which are too high for a purely physical process and suggest that a chemical process is involved in the action of quaternary ammonium salts".

The work of Bigland *et al.*, however, would seem to eliminate from these chemical processes the hydrolytic phase.

On the other hand, Lonsdale and Milledge<sup>5</sup>, from consideration of the decamethonium temperature effect of ref. 2, and the X-ray crystal structure determination of hexa- (HM) and deca-methonium dibromide dihydrates, put forward the two following hypotheses:

(i) That the capacity of the N<sup>+</sup> quaternary group for electrostatic binding with the receptors can be dismissed, because in the crystal structure, "the distances from N to other atoms not in the same chain are all greater than 4.26 Å. The N atoms are so well shielded that it is difficult to see how they could take part in any specific attachment respect of the curare-like 'pharmacological' action of the methonium salts."

(ii) "That increased efficiency of action on cooling is easily understood in terms of numerous van der Waals attachments, since these will be sensitive to thermal vibration, especially of the more mobile methyl group."

In agreement with published views<sup>6</sup> that "if the same rules apply to the forces acting in the solid state as those in the adsorption state, these rules would be particularly applicable between the blocking agents and the receptor sites . . .", an intensive examination of the foregoing facts and hypotheses was carried out by me with evidence from the overlapping fields of physical chemistry, crystallography and pharmacology, as a result of which different conclusions are reached. Of these, the first three directly concern the mechanism of the temperature effect in neuromuscular blocking activity by DM and TMA, whereas all five conclusions are related to the specific equilibrium of forces acting in the adsorption and solid state of several drugs.

(1) The solubility data of methonium derivatives in polar and non-polar solvents indicate that in these compounds the coulombic forces, even if reduced, are more significant than the van der Waals forces; in the tetra-alkyl salts the influence of the van der Waals forces grows with the length of the alkyl radicals.

(2) Electrolytic, thermochemical and radiodecomposition data show that the N<sup>+</sup> quaternary group behaves as if the positive charge were at its centre.

(3) An important factor in explaining the increased blocking activity of DM for small decreases in the tem-

perature of the receptor membrane is its very steep solubility gradient with temperature in water. A similar factor should act in the regulation of the temperature effect of the blocking activity of TMA.

(4) Although there is sometimes a tendency, in the crystallographic field, to neglect distances of more than 4 Å between differently charged ions, it is shown that these coulombic forces acting over long distances play an important part in both solid and adsorption states.

(5) The positions in which pentamethonium and hexamethonium in relation to a flat receptor surface possess maximum coulombic and van der Waals binding energies are shown in Fig. 1. The number of van der Waals contacts are different from those suggested in Table 1 of ref. 4. The mechanism of the blocking activity of the bis-N-methylpyrrolidinium series is discussed later in this communication. Evidence in support of the above conclusions is as follows:

**Physico-chemical examination: solubilities.** There is evidence that, in aqueous solution, the tetraalkylammonium ions appear to be unhydrated with a low surface charge<sup>7</sup>, and that the interactions of the alkyltrimethylammonium<sup>8</sup> and alkylammonium<sup>11</sup> with enzymes have a hydrophobic character.

The presence of a low surface charge, unexplained in ref. 9, and circumvented in ref. 27, can be accounted for by the dipoles induced by the N<sup>+</sup> charge on the surrounding four alkyl groups.

This is equivalent to a dielectric constant that weakens the attachment by coulombic forces, and, therefore, the amount of crystal lattice energy of the N<sup>+</sup> quaternary salts will approach that of the hydrogen-bonded type of crystal lattices. Thus, this new hydrophobic type of hydrogen bond is highly relevant to the adsorption by the biological membranes of N<sup>+</sup> quaternary groups, and is in agreement with Pauling's views<sup>12</sup> that, in nervous transmission and muscle contraction, "... the hydrogen bond is the only strong and directed intermolecular interaction which can come into operation quickly".

The presence of a positive charge on the methyl of the N<sup>+</sup> quaternary group has been suggested by Thomas and Marlow<sup>13</sup>, but only on speculative grounds from the properties of NH<sub>4</sub><sup>+</sup>. Their views have been opposed by Belleau and Lacasse<sup>14</sup>, who argue that the presence of residual positive charges would confer a degree of hydration to the N<sup>+</sup> quaternary group. However, their statement is not borne out by the experimental electrolytic evidence<sup>9</sup> or that of nuclear magnetic resonance (Canepe, F. G., and Mooney, E. F., unpublished results), from which it appears that, in aqueous solution, the three methyls of the N<sup>+</sup> groups of acetylcholine, hexamethonium and decamethonium rotate about the chain N-C axis. Thus, this physical evidence of the absolute hydrophobic character of the N<sup>+</sup> quaternary group in dilute aqueous solution represents it as a dynamic equilibrium between the CH<sub>3</sub> and the water dipoles, and confirms the earlier observations reviewed by Ing and Wright<sup>6</sup>. From the solubility data (Table 1), and the N<sup>+</sup> group radii, it can be assumed that the reduced coulombic forces are predominant in both the TMA ion and trimethylmethonium<sup>9</sup> series.

The ionic limiting conductances  $\lambda_0$  for tetra- and penta-<sup>15</sup>, hexa- and decamethonium<sup>16</sup>, and tetraalkylammonium ions<sup>17</sup>, show that the methonium compounds are highly ionic in solution. Halliwell and Nyburg<sup>18</sup> have reviewed the thermochemical evidence, from several

Fig. 1. Maximum binding energy in the adsorption state. (a) For pentamethonium chain, (b) for hexamethonium chain

authors, on the enthalpies of hydration of  $\text{Li}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Rb}^+$ ,  $\text{Cs}^+$ ,  $\text{Ph.N}_4^+$  and  $\text{NMe}_4^+$ .

Plotting the absolute enthalpies of hydration against the effective ionic radii of respective ions gives a simple curve. Hence we observe that evidence given in refs. 9 and 18 indicates that the  $\text{NMe}_4^+$  behaves as if the positive charge were at its centre. Moreover, the close relationship that appears to exist between the betaine and choline chains in the mechanism of their radiation decomposition<sup>18</sup> brings further evidence for the state of the  $\text{N}^+$  quaternary group.

**Blocking activity of decamethonium and tetramethylammonium temperature effect.** The increase of the solubility of decamethonium iodide in water from 22° to 100° C is fiftyfold, an increase for each °C equivalent to 64 per cent of the initial solubility of 22° C. This extraordinary behaviour in a polar medium such as water, the nearest to the physiological medium, is a more relevant factor to the diminished neuromuscular blocking activity of DM, when the temperature increases by a few degrees, than the hypothesis of van der Waals attachment suggested by Lonsdale and Milledge<sup>4</sup>.

Although the kinetic equilibrium of the adsorption state phase between the receptor membrane charges and those of the  $\text{N}^+$  groups of decamethonium takes place in a hydrophobic layer-medium, it experiences through its boundary equilibrium with the surrounding aqueous or near-aqueous physiological phase the temperature solubility's variation of decamethonium.

Paton and Zaimis<sup>19</sup> have shown that some aspects of decamethonium adsorption state behaviour at the receptor membrane are acetylcholine-like. Wilson and Cabib<sup>21</sup>

have found that acetylcholine adsorbability (the reciprocal of the Michaelis-Menten constant) on the receptor membrane does not vary with temperature in the interval 15°–30° C, which can be extrapolated to 5°–35° C. Now the attachment of the  $\text{N}^+$  groups of Ach and decamethonium to the membrane is mainly electrostatic. Therefore, we are justified in using the electrostatic criteria rather than the kinetic considerations. Then, the foregoing findings of Wilson and Cabib<sup>21</sup> are in accordance with the experimental fact that in the solid state the variations of the long-range coulombic forces with temperature are much smaller than those of the short-range van der Waals forces, that is, the latter very high distance specificity is very sensitive to thermal displacements produced by variations of temperature. The larger Michaelis-Menten constants observed for increased substitution of hydrogen for the  $\text{OH}_2$  of the  $\text{N}^+$  group of Ach are an indication of increased hydration, that is, repulsion from the hydrophobic receptor surface.

In conclusion, it is reasonable to assume that, for decamethonium, the variations of the Michaelis-Menten constants with small variations of temperature are much smaller than the correspondingly high variations of its solubility, the latter factor being therefore responsible for the temperature effect of its neuromuscular blocking activity, despite the solution of the drug being diluted.

The solubility gradient (between 20° and 100° C), and the increase of blocking activity for 4° C of cooling, of TMA and DM should stand in similar ratios, 6.2/50 and 0.6/4 respectively.

If Ing and Wright<sup>3</sup> have firmly rejected the importance of solubility in the temperature effect, and on curariform

activity<sup>22</sup>, this was probably because the available data on the curariform activity of the trimethyl alkylammonium cations were incorrect, as can be seen by comparing their evidence with that reviewed by Bovet and Bovet-Nitti<sup>23</sup>.

It is well known that Ach activity is enhanced by cooling. Because Ach has a solubility gradient (data yet to be published), the postulated mechanism for the temperature effect of DM and TMA can be applied to Ach, which is also in agreement with the additivity of their depolarizing cholinergic effects.

Much lower concentrations of Ach are required at neuromuscular junctions for producing similar effects to those of the foregoing drugs<sup>24</sup>. As the formation process of Ach is not altered by them, the accumulation of Ach at the junction will compensate partially for the speed of elimination of DM or TMA, enhancing the duration of their blocking activity.

An increase in drug concentration in the membrane is produced by cooling; the magnitude of the block will be increased if a greater number of available receptors are occupied; the excess of the drug will affect the duration.

Bigland, Goetzee, MacLagan and Zaimis<sup>1</sup> suggest that "cooling influences the process by which a long-lasting depolarization of the motor end-plate interrupts neuromuscular transmission", but no mechanism is given. The above statement becomes clearer if the solubility gradient mechanism is introduced as a process. These authors also suggest that the temperature effect mechanism of the N<sup>+</sup> quaternary depolarizing drugs can be compared with that acting during the depolarizing action of an excess of K<sup>+</sup> ions at the receptor membrane. This view must be considered with great caution because:

(i) The aqueous solubility gradient of KCl is less than a quarter of that of TMA iodide, that is, temperature effect variations are within experimental errors if cooling is 3°–4° C only.

(ii) The K<sup>+</sup> ions are not hydrophobic, unlike the N<sup>+</sup> group.

(iii) There is an enzyme mechanism that regulates the concentration of K<sup>+</sup> ions on both sides of the receptor membrane.

Finally, from the solubility data of Table 1 it follows that a possible temperature effect operates on the ganglion-blocking activity of non-depolarizing drugs which should be less marked for the hexamethonium than for the pentamethonium substrate—their action being competitive.

**Forces in the adsorption state.** It is known that the blocking activity of the (CH<sub>3</sub>)<sub>n</sub>N<sup>+</sup>—(CH<sub>2</sub>)<sub>n</sub>—N<sup>+</sup>(CH<sub>3</sub>)<sub>n</sub> series is a function of *n* and of the receptor membrane properties<sup>25</sup>.

Since 1962 I have accumulated evidence showing that this blocking activity is also a function of the distribution of the coulombic forces surrounding the N<sup>+</sup> quaternary groups at the receptor membrane surface. For example, in Fig. 1 it can be observed that the extended methonium chains with an uneven number of CH<sub>2</sub> have their two positive charges along one side (PP') of the chain's plane, whereas the even chains have their positive charges along the diagonal (BB') of the chain's plane; PP' and BB' are axes of electrostatic attachment. Thus, when extended, the adsorbed methonium even chain will have either of its sides BB' parallel to the plane of the receptor, with only four CH<sub>2</sub> van der Waals contacts.

If, and only if, the bulky N<sup>+</sup> terminals of the extended hexamethonium chain could rest inside cavities 0.7 Å deep, nine to ten van der Waals contacts would be possible and not 3 + 3 as calculated in Table 1 of ref. 4. These cavities would not fit other chains of different lengths, such as pentamethonium, which has seven contacts in Fig. 1, that is, the sum of the van der Waals and the coulombic binding energies is maximum when the electrostatic axis PP' is about 0.5 Å from the flat receptor's surface. There are only four contacts if PP' is 0.84 Å distant from the receptor's surface, that is, the

sum of the electrostatic and van der Waals binding energies is minimum if during the adsorption state the chain's plane is perpendicular to the receptor. These contacts differ from those given in ref. 4, Table 1 (2 + 3 and 3 + 3), which are valid only for the crystalline state, and not for the adsorption state where the influence of the electrostatic axes of types PP' and BB' must be considered relative to the receptor plane. By the latter method it is possible to explain the differences in ganglion-blocking activity of the trimethylmethonium series and the polymethylene bis-N-methylpyrrolidinium series.

In ref. 4 the probable chain length of the methonium bis-cations in the physiological medium<sup>24</sup>, and the summation of the non-indifferent energy barriers of 800 cal/mole for each of the bond rotations, from a skew to a *trans* position, necessary in order to stretch fully the odd or even methonium chains at the receptor site as required in their hypotheses, are ignored, as also are the forces necessary to carry out this work at the receptor membrane.

**Crystallographic examination.** In the pentamethonium iodide crystal structure<sup>26,27</sup>, the expected N<sup>+</sup>—...I<sup>−</sup> maximum distance is the sum of the N—C bond = 1.47 Å plus the van der Waals radii of CH<sub>3</sub> = 2 Å and I<sup>−</sup> = 2.15 Å, then N<sup>+</sup>—...I<sup>−</sup> max = 5.62 Å. The maximum N<sup>+</sup>—...I<sup>−</sup> distance should diminish about 0.5 Å when a hard anion is attached between two methyls and about 0.9 Å when attached inside the cavity at the intersection of the van der Waals spheres of the three-methyl group.

Therefore, if the recorded N<sup>+</sup>—...I<sup>−</sup> distances, for one N<sup>+</sup> group only, are 4.43, 5.14, 5.19, 5.28, 4.66, 4.51 ± 0.14 Å, they are all well within expectations; they indicate the presence of twelve coulombic forces per chain, which significantly increase, for example, the angles C<sub>1</sub>N<sub>1</sub>C<sub>2</sub> and C<sub>2</sub>N<sub>1</sub>C<sub>3</sub>, and diminish the angles C<sub>1</sub>N<sub>1</sub>C<sub>4</sub> and C<sub>1</sub>N<sub>1</sub>C<sub>5</sub> (see ref. 25, page 106, Fig. 7a1).

Pressman, Grossberg, Penoe and Pauling<sup>28</sup> have evaluated coulomb interaction energy between the charged haptene group and the antibody's N<sup>+</sup> quaternary group for *r* = 7 Å, which is well above the value of 4.26 Å of ref. 4.

I have not considered the binding energy due to the increased van der Waals distances between C—O of different chains because of their weakness in relation to the long-range coulombic forces, the energy of the former being a function of 1/*r*<sup>6</sup> as compared with 1/*r* for coulombic binding energy (see Fig. 1, page 149, ref. 26).

In ref. 26 the standard deviations of the inter-atomic distances are given as *r*<sub>1</sub>—...I<sup>−</sup> ± 0.02 Å, *r*<sub>1</sub>—...N<sup>+</sup> ± 0.14 Å, *r*<sub>1</sub>—...O ± 0.17 Å and *r*<sub>0</sub>—...O ± 0.23 Å. Neglecting the Madelung constant, it is simple to obtain an approximate assessment of the reduced coulombic binding energy *E*(1/*r*<sup>2</sup>), in terms of the twelve observed N<sup>+</sup>—...I<sup>−</sup> distances per pentamethonium chain.

Alternatively, as is implicit in the hypotheses of Lonsdale and Milledge<sup>4</sup>, a rough estimate of the binding energy (excluding the van der Waals energy) could be ascertained by means of the more numerous but less-accurate distances *r* of the type I<sup>−</sup>—...CH<sub>2</sub>, CH<sub>2</sub>—...CH<sub>2</sub>, CH<sub>2</sub>—...CH<sub>2</sub> as a function of 1/*r*<sup>2</sup>, where 1 < *n* < 6 and the forces involved change for a given type of *r*. A list of the I<sup>−</sup>—...O ten distances ≤ 4.15 ± 0.17 Å for a whole pentamethonium chain is given in ref. 25, page 109, the smallest being *r* = 3.75 ± 0.17 Å.

**Pharmacological examination.** In ref. 4, in accordance with Table 1, it is stated, from consideration of pharmacological tests carried out on one type of tissue only, that the mechanism of the blocking activity for the *n*-methonium chains "is rather dependent on the extreme CH<sub>2</sub>—...CH<sub>2</sub> distances on each side of the chain and on the number of possible van der Waals contacts within those extremes". Also the critical distances of optimum ganglion and neuromuscular blocking activity are given as 10 Å and 15 Å and the conclusion drawn that the blocking activity of molecules with CH<sub>2</sub>—...CH<sub>2</sub> distances different from the above would be small because 'easily detachable'.

It should be noted, however, that pempidine, which is considerably shorter than 10 Å, is a highly active ganglion-blocking agent of protracted action<sup>22</sup>. Although changes on the extreme OH<sub>1</sub>...OH<sub>2</sub> distances are produced when two C<sub>2</sub>H<sub>5</sub> groups are substituted for 2OH<sub>1</sub> in each of the N<sup>+</sup> terminals of tetra, penta and hexamethonium<sup>23</sup>, the activities of the di-substituted tetra-, penta- and hexa-derivatives in the cat superior cervical were 100, 125 and 75 units instead of 1, 65 and 100 units of activity before the substitution. In the guinea-pig ileum<sup>24</sup>, the new activities were 25, 100 and 100, instead of 5, 75 and 100.

The critical distance of 15 Å for the optimum blocking activity at the neuromuscular junction<sup>4</sup> is no less arbitrary than that of 10 Å for ganglion-blocking activity. Paton and Zaimis<sup>25</sup> have shown that for different types of membrane the maximum blocking activity ranges between DM to dodecamethonium and that DM's activity varies greatly according to the species of animals tested:

DM activity in cat > rabbit > monkey > mouse > rat

$$\frac{\text{DM activity in cat}}{\text{DM activity in rat}} \approx 200$$

A similar di-substitution produces very different effects in the ganglionic and neuromuscular blocking activities of hexamethonium<sup>26</sup> and decamethonium<sup>27</sup>. This difference of adsorption behaviour, and the fact that only the latter depolarizes the receptor membrane, cannot be explained by weak van der Waals forces alone, but could be if to them were added the predominant action of the reduced coulombic forces.

The combined effects of these forces provide a rational explanation of the very different blocking mechanisms of, for example, pempidine, trimethylalkylammonium series, trimethylmethonium series, polymethylene bis-N-methyl pyrrolidinium series and the substituted derivatives

mentioned above, which will be dealt with in a separate paper under preparation.

I thank Dr. W. J. Barry, Dr. H. R. Hudson and Mr. H. A. Knight for help and advice.

## RELATIONS BETWEEN ACETYLCHOLINE, CHOLINE AND BETAINE CHAINS IN AQUEOUS SOLUTION

By Dr. F. G. CANEPA

Department of Physics, Northern Polytechnic, London, N.7

### Radiation Decomposition Mechanism of Betaine and Choline Chains

CRYSTALLINE orthorhombic choline chloride (Ch.Cl) at room temperature is very sensitive to ionizing radiation<sup>1</sup> and the choline ion breaks down mainly into trimethylamine and acetaldehyde<sup>2</sup>:

Lemmon *et al.*<sup>3</sup>, after investigating the effects of ionizing radiation on Ch.Cl and its analogues, concluded that: (i) choline bromide is about one-third as sensitive as the chloride. None of many other analysed analogues, including choline iodide (Ch.I), shows abnormal radiation instability; (ii) Ch.Cl susceptibility to radiation damage is a function of its crystal structure, as shown by its contrasting stability in solution; (iii) the high values of molecular decomposition per 100 eV indicate a chain mechanism for the solid-state reaction.

The crystal structure of the orthorhombic phase of Ch.Cl was published by Senko and Templeton<sup>4</sup>. Data on the cubic disordered reversible phase, stable over 73° C, were given by Collin<sup>5</sup>, who suggested that the transition to the disordered cubic phase and the subsequent increased stability to radiation furnished further evidence that the

decomposition was highly stereospecific. From their crystallographic evidence the authors were not able to find a mechanism which accounted for the foregoing facts.

Serlin<sup>6</sup> reported that for γ-radiation the decomposition of crystalline Ch.Cl per 100 eV absorbed was higher at 50° C than at 20° C, but at 160° C the solid Ch.Cl was much more stable than at room temperature.

Finally, Lemmon *et al.*<sup>7,8</sup>, although still unable to find an explanatory mechanism, produced the following relevant evidence from their isotopic investigations of the radiation decomposition of crystalline Ch.Cl: "(i) the carbinol group of the ethanol moiety becomes the aldehyde group of the resultant aldehyde; (ii) no hydrogens are transferred to or from the trimethylamino-group; (iii) the hydrogens of the ethanol moiety are highly mobile; (iv) intermolecular hydrogen transfers take place".

Because X-ray diffraction data obtained under irradiation conditions provide a reliable quantitative picture of the behaviour of the Ch. and Cl<sup>-</sup> ions during the collection of the diffraction measurements, I have made an intensive examination of the combined crystallographic evidence from the structures of tetramethylammonium (TMA)<sup>9,10</sup> halides, muscarine iodide<sup>11</sup>, pentamethonium iodide<sup>12</sup>, choline chloride<sup>4</sup>, hydroxylammonium chloride<sup>13</sup>, hydrogen chloride monohydrate<sup>14</sup> and acetylcholine bromide (Canepa, Pauling and Sorum, work in preparation). As a

result of this examination, a mechanism was found for the radiation decomposition of Ch.Cl, the attenuated decomposition of Ch.Br, the insensitivity of Ch.I to radiation, the temperature effect on the rate of their decomposition and a similar mechanism for the radiation decomposition of betaine hydrochloride, based on the following evidence:

Ch.Cl orthorhombic structure can be defined as an infinite molecule with cations and anions bound by a mixture of weak electrostatic forces and even weaker hydrogen bonds. The dipole moment of the  $\text{CH}_3$  groups<sup>15,16</sup> acts as a dielectric constant reducing the coulombic forces between the  $\text{N}^+$  quaternary group and the  $\text{Cl}^-$  anions and will be dealt with in a later communication.

In the published Ch.Cl structure<sup>4</sup>, because the  $\text{Cl}^- \dots \text{O}$  distance is 3.03 Å, instead of 2.95 Å as in hydrogen chloride, 2.91 and 2.99 Å in tropolone hydrochloride, and 2.99 Å in hydroxylammonium chloride, the conclusion was reached by Senko and Templeton that the hydrogen bonds, if present, were very weak. Nevertheless, a calculation with their published co-ordinates (see Figs. 1 and 2) shows the angle  $\text{C}_4\text{C}_3\text{O} \approx 102.5^\circ$ , instead of the expected  $108^\circ$ – $110^\circ$ , and the  $\text{N}^+ \dots \text{O}$  distance 3.26 Å only, as compared with the shortest of the six  $\text{N}^+ \dots \text{Cl}^-$  electrostatic co-ordination distances: 4.08, 4.22 and 4.28 Å; moreover the non-bonded  $\text{C}_1 \dots \text{C}_2$  carbons, 3.3 Å apart instead of a minimum of 4 Å, are the seat of repulsive forces. The foregoing three factors indicate a very significant electrostatic binding between the  $\text{N}^+$  group and the alkyl oxygen. A comparative calculation with the public co-ordinates of muscarine iodide gives an even shorter  $\text{N}^+ \dots \text{O}$  distance of 3.07 Å, and the shortest of its six  $\text{N}^+ \dots \text{I}^-$  distances as 4.49 Å, suggesting a stronger electrostatic binding in the  $\text{N}^+ \dots \text{O}$  system of muscarine. Thus, there is in Ch.Cl structure a balance of forces between the pulls exerted by  $\text{N}^+$  and by  $\text{Cl}^-$  on the oxygen in the electrostatic system (A) which:

accounts for the longer  $\text{N}^+ \dots \text{O}$  distance (3.26 Å), that is, weaker electrostatic binding, and for the longer  $\text{O}-\text{H} \dots \text{Cl}^-$  (3.03 Å).

A comparison of the  $d-r$  values of Ch.Cl and TMA.Cl in Table 1 shows that repulsive forces between anions increase with the ionic co-ordination (see Ch.Cl and TMA.Cl) but not with anionic radii (see TMA halides). Therefore, it is likely that the 11 per cent increase of unit cell volume during the Ch.Cl transition from orthorhombic to the cubic phase is due to the disorder of the new phase and to a change from the distorted six-fold to the distorted eight-fold electrostatic co-ordination, the latter increasing the value of  $\text{N}^+ \dots \text{Cl}^-$  distance from 4.08 to, say, 4.38 Å as in TMA.Cl (see Table 1).

This decreased binding energy in the expanded  $\text{N}^+ \dots \text{Cl}^-$  distances of Ch.Cl cubic form allows a stronger  $\text{N}^+ \dots \text{O}$  electrostatic interaction which should cause the  $\text{N}^+ \dots \text{O}$  distance to decrease from 3.26 Å to at least 3.07 Å. This is the  $\text{N}^+ \dots \text{O}$  distance in the six-fold distorted muscarine iodide and possibly in the four-fold co-ordinated acetylcholine chloride. Because of the increased  $\text{N}^+ \dots \text{Cl}^-$  and decreased  $\text{N}^+ \dots \text{O}$  dis-

Fig. 1.  $\text{Ch}^+$  in Ch.Cl orthorhombic phase.  $\delta$  atomic co-ordinates given.  $\text{C}_1 \dots \text{C}_2$ , 2.65 Å;  $\text{N}^+ \dots \text{C}_1$ , 2.68 Å;  $\text{O} \dots \text{C}_1$ , 2.45 Å;  $\text{C}_3-\text{O}$ , 1.99 Å

Fig. 2.  $\text{N}^+ \dots \text{Cl}^-$  and  $\text{Cl}^- \dots \text{Cl}^-$  distances in Ch.Cl orthorhombic phase

tances a weakening of the hydrogen  $\text{O}-\text{H} \dots \text{Cl}^-$  is implied in the expanded unit cell of cubic Ch.Cl.

The consequence of the foregoing is the greater stability of the Ch.Cl cubic phase to radiation decomposition. This will be better understood after a close examination of the atomic thermal displacements under X-ray irradiation in the compounds listed in Table 2.

The temperature factor is  $B_i = 8\pi^2 \langle u_i^2 \rangle$ , where  $\langle u_i^2 \rangle$  represents the isotropic mean square displacement of the atoms in the X-irradiated crystal structure and  $i = \text{O}, \text{N}, \text{Cl}$ , etc., depending on the chemical composition of the structure. Relevant also to the radiation decomposition mechanism is the greater mobility of the hydrogen atoms (higher values of  $B$ ) relative to X-irradiated heavier atoms which occur in most X-ray crystal structures.

If the thermal displacements  $\langle u_i^2 \rangle$  of the orthorhombic Ch.Cl (see Table 2 following) were really isotropic, then the maximum additive displacements of  $\text{N}^+ \dots \text{Cl}^-$ ,

Table 1

	Ch.I	Ch.Br. orthorhombic	Ch.Cl	Ch.Cl cubic	TMA.Cl tetragonal	TMA.Br tetragonal	TMA.I [tetragonal]

Table 2

Ocholine chloride orthorhombic at room temperature	Atom	Cl	O	N	C <sub>1</sub>	C <sub>2</sub>	C <sub>3</sub>	C <sub>4</sub>	C <sub>5</sub>
	B in Å <sup>2</sup>	5	6	4	5	7	5	7	7
	w in Å	0.252	0.276	0.225	0.207				
Hydrogen chloride monohydrate at -25° C	Atom	Cl <sub>1</sub>	Cl <sub>2</sub>	O <sub>1</sub>	O <sub>2</sub>	H			
	B	0.035	-0.007	0.041	-0.016	5.0			
	w	0.0214				0.195			
Hydroxylammonium chloride NH <sub>2</sub> OHCl	Atom	Cl	O	N					
	B	1.5	1.5	1.5					
	w	0.138	0.138	0.138					

N+....O and O....Cl- would be  $u_{Cl} + u_N \approx \pm 0.48 \text{ Å}$ ,  $u_N + u_O \approx \pm 0.5 \text{ Å}$ ,  $u_{Cl} + u_O \approx \pm 0.53 \text{ Å}$ .

The evidence as to the relevance of thermal displacements in the oscillatory behaviour of the loosely bound tetrahedral system (A) under irradiation is provided by the resultant products of the radiation decomposition.

The already strained bond N—C<sub>4</sub> of 1.6 Å length, joining the two branches of the gauche OH<sup>+</sup> chain, is stretched further if the atoms C<sub>3</sub> and O of one branch close up towards N<sup>+</sup> and C<sub>5</sub> on the other branch due to thermal displacements assisted by the high energy of the γ-radiation (see Fig. 1).

This compresses the N+....O and O<sub>3</sub>....C<sub>5</sub> distances so that the N—C<sub>4</sub> bond breaks. The increased N<sup>+</sup> induction on the O—H group repels the highly mobile hydrogen atom towards either the hydrocarbon chain (i) or the Cl- (ii).

In either, a pressure wave is set up and transmitted through the highly compressed orthorhombic structure of Ch.Cl (volume 763 Å<sup>3</sup>) due to the van der Waals forces originating from the molecules produced in the radiation decomposition because these require a van der Waals space greater even than that available in the expanded cubic phase of Ch.Cl (volume 857 Å<sup>3</sup>).

The already existing thermal displacements, the γ-radiation and the new pressure wave further compress all the N+....O and C<sub>3</sub>....C<sub>5</sub> systems in the contiguous Ch<sup>+</sup> chains, resulting in additional decomposition of the chain reaction type.

### Acetylcholine Conformation in Aqueous Solution

The great stability to irradiation of the Ch<sup>+</sup> cations in the aqueous solutions of Ch.Cl is accounted for by:

(i) The coulombic forces between the hydrophobic N<sup>+</sup> group and the hydrated Cl- anions are reduced as compared with that in the crystalline state, since besides the OH<sub>2</sub> dipoles surrounding the N<sup>+</sup> there are the water dipoles around the Cl-. Thereby the N+....Cl- distances in solution are greater than in the crystalline phases.

(ii) This strengthens the binding energy of N+....O, shortening its distance to at least 3.07 Å as in muscarine iodide crystal structure, leaving the O—H system too weak to compete with the water molecules for the Cl- anions. Because in aqueous solution the chain Ch<sup>+</sup> does not contain the irradiation sensitive oscillatory system (A) it is far more stable to the γ-rays. Moreover, in the aqueous medium the high-energy γ-radiation impact on the Ch<sup>+</sup> chains can be kinetically absorbed by recoil movements of these cations.

(iii) This Ch<sup>+</sup> chain stability towards irradiation in solution is the first strong indirect evidence relating the forces acting on Ch<sup>+</sup> in the solid state to those acting on Ch<sup>+</sup> in solution. Thus the N+....O distance of Ch<sup>+</sup> in solution is similar to that of Ach. in Ach.Br crystal structure and gives to both cations because of their hydrophobic N<sup>+</sup> group a quasi-zwitter ion or quasi betaine character only in aqueous solution. This completes the

analysis of the infra-red evidence of Ach. in aqueous solution of Canepa and Mooney<sup>17</sup>, where a ring conformation due to the N<sup>+</sup> group and the carbonyl oxygen of Ach. was ruled out.

The N+....O conformation in the Ach. solid state and in aqueous solution is relevant to its adsorption at the cholinergic receptor and its hydrolysis. This provides another striking example of the relations between the forces acting in the solid state and those acting in the adsorption state<sup>18</sup>: I shall deal with these in a subsequent communication.

**Decomposition of Ch.Br compared with the stability to irradiation of Ch.I.** It can be seen from the first part of Table 1 that the repulsive forces between the anions co-ordinating the N<sup>+</sup> group in the TMA halides decrease when the radii of the anions increase; as a consequence, the volume of the rigid cationic TMA<sup>+</sup> group, plus inter-ionic interstices, is minimum for TMAI. Conversely, the second part of Table 1 shows that in the crystalline state the available amount of cationic volume in the Ch. halide is maximum for Ch.I and minimum for Ch.Cl. It follows from the negative values of  $\delta v$  that the N+.... halide compression is greater for Ch.Cl than for Ch.Br; therefore, the corresponding N+....O distance in the oscillating system (B):

is intermediate between 3.26 and 3.07 Å, that is, the N+....O bridge joins the branches of the gauche chain of Ch<sup>+</sup> in the Ch.Br crystal structure with a rigidity intermediate between that of Ch.Cl and that of Ch.I, which accordingly reduces the Ch<sup>+</sup> thermal displacements and with it the rate of radiation decomposition of Ch.Br.

The value of the temperature factor  $B = 8\pi^2 u^2$  is minimum when the Ch.Cl molecule is in the ground state (zero point energy), and increases steadily with the temperature for a given crystalline phase. The almost zero thermal displacement at liquid air temperature explains the stability of Ch.Cl in such conditions, whereas the growth of the rate of radiation decomposition must coincide with rising temperature.

It is possible to suggest the decomposition mechanism of betaine hydrochloride on similar lines to (B); the oxygen charge, being located between the CH<sub>3</sub> groups, where their dielectric constant is a minimum, is strongly attracted towards the centre of the N<sup>+</sup> group.

I thank Dr. C. G. Smith for his help and advice.

# CHLOROGENIC ACID: FURTHER EVIDENCE FOR ITS ANTIGENIC AND ALLERGENIC ACTIVITY

By D. S. BARIANA, J. KRUPY, L. M. SCARPATI, S. O. FREEDMAN and A. H. SEHON

Departments of Biochemistry and Chemistry, McGill University, McGill University Medical Clinic, Montreal General Hospital, Montreal, Canada, and Istituto di Chimica Organica, Università di Roma, Italy

PREVIOUS investigations<sup>1-3</sup> in these laboratories demonstrated that chlorogenic acid was an important allergenic constituent of green coffee bean. This simple phenolic compound, which is the depside of caffeic and quinic acids (Fig. 1), accounts for 6-8 per cent of the dry weight of the green coffee bean. Coffee workers who developed asthma or rhinitis on exposure to finely dispersed coffee dust showed wheal and erythema responses when tested intradermally with chlorogenic acid, and positive Prausnitz-Kustner passive transfer reactions were obtained when chlorogenic acid was injected into human skin sites sensitized with the sera of the allergic workers. Furthermore, it was demonstrated that free chlorogenic acid was capable of inducing the formation of circulating antibodies in animal species<sup>4</sup>.

Fig. 1. Chlorogenic acid

Recently all these findings were challenged by Layton *et al.*<sup>5,6</sup>, who reported that a 'pure' chlorogenic acid prepared in their laboratories was inactive when tested by passive cutaneous anaphylaxis in monkeys sensitized with the sera of individuals allergic to green coffee bean. Moreover, it was suggested that the immunological activity of chlorogenic acid described by us was attributable to trace amounts of a protein impurity which had not been removed during its isolation from plant sources. In their criticism, however, Layton *et al.*<sup>6</sup> omitted reference to the fact that in an earlier publication<sup>4</sup> from these laboratories it was stated that synthetic chlorogenic acid (prepared by one of us, L. M. S.<sup>7</sup>) was found to be highly active on both direct and passive transfer skin testing in man. The purpose of the series of experiments recorded here was to prepare chlorogenic acid-protein conjugates, to investigate their antigenic and allergenic properties, and to provide additional evidence for the immunological capacity of chlorogenic acid.

Two types of hapten-protein conjugates were synthesized. In the first procedure, chlorogenic acid was cross-linked by formaldehyde to the amino-groups of human serum albumin (HSA) by the Mannich reaction (Fig. 2) using the conditions recommended by Fraenkel-Conrat<sup>8</sup>. About 15-18 molecules of chlorogenic acid were coupled per molecule of HSA in this reaction. The conjugates prepared by the Mannich reaction will be referred to as conjugates I for the remainder of this article.

In the second procedure an attempt was made to reproduce the biological conditions for the conjugation, as they might occur in living tissues. Although no precise information regarding the metabolic fate of chlorogenic acid is yet available, a hypothetical mechanism for the

*in vivo* conjugation of an *o*-diphenol such as chlorogenic acid can be postulated. Phenol oxidases which are widely distributed throughout mammalian tissues catalyze the dehydrogenation of *o*-diphenols to *o*-quinones, which in turn have been shown to combine readily with the free amino-groups of proteins<sup>9</sup> according to the scheme outlined in Fig. 3. Therefore, the second type of chlorogenic acid-protein conjugates was prepared by the reaction of chlorogenic acid with HSA in the presence of phenol oxidase for 2-5 h at pH 6-2; these conjugates will be referred to as conjugates II. It was deduced, by measuring the decrease of free amino-groups of HSA, that as many as 40 hapten molecules were coupled per molecule of HSA.

The chlorogenic acid used to prepare these conjugates was either a synthetic sample<sup>7</sup> or a commercial sample of plant origin supplied by the Aldrich Chemical Co., Milwaukee, Wisconsin. The latter sample of natural chlorogenic acid was recrystallized three times from water in our laboratories, and was found to be free of detectable nitrogen on microanalysis performed by the Schwartzkopf Laboratory, Woodside, New York. Both types of conjugates were freed of any unreacted chlorogenic acid by extensive dialysis and column chromatography on 'Sephadex G-25'. Phenol oxidase (mushroom tyrosinase) was purchased from the Nutritional Biochemical Corporation, Cleveland, Ohio.

Fig. 2. Coupling of chlorogenic acid with formaldehyde

Fig. 3. Coupling of chlorogenic acid to proteins in presence of phenol oxidase

Rabbit antisera were prepared against both types of conjugates, as well as against a solution of free chlorogenic acid and an aqueous extract of green coffee bean. Human sera were obtained from coffee workers with respiratory allergy to green coffee dust. The antisera were produced against the two types of chlorogenic acid-HSA conjugates were absorbed with HSA prior to their use in immunochemical experiments.

The results of immunodiffusion experiments in agar gel are illustrated in Figs. 4-6. It will be noted that conjugate I gave a single precipitin band with the rabbit antiserum to conjugate I, with the antiserum to free chlorogenic acid or with the antiserum to green coffee (Fig. 4). Furthermore, the three precipitin bands coalesced, indicating a reaction of identity for the three antigen-antibody systems. It would thus appear that chlorogenic acid is an important antigenic constituent of the green coffee bean. The immunodiffusion patterns illustrated in Fig. 5 demonstrate complete cross-reactivity between conjugates I and II when tested against their corresponding antisera; this finding provides further evidence that the antigenic determinant groups are identical for both types of conjugate. From the patterns illustrated in Fig. 6, it is evident that multiple precipitin bands were formed when green coffee extract was tested against antiserum to green coffee. It is also apparent that one of the constituents of green coffee has an antigenic determinant group in common with conjugates I and II, as well as with free chlorogenic acid. Moreover, all the precipitin bands shown in Figs. 4-6 were specifically inhibited with both synthetic and nitrogen-free natural chlorogenic acid, except for some

Fig. 4. The reaction of identity among rabbit antibodies to chlorogenic acid (Anti-C.A.), to the extract of green coffee bean (Anti-coffee) and to conjugate I (Anti-conj I), when tested with conjugate I (Conj I). Normal rabbit serum was placed in the well marked as 'control'.

Fig. 5. Antigenic cross-reaction between conjugates I and II when tested with the corresponding rabbit antisera.

Fig. 6. Precipitin patterns obtained in agar gel between extract of green coffee bean and antisera to chlorogenic acid (Anti-C.A.), to conjugates I and II (Anti-conj. I and Anti-conj. II) and to the extract of green coffee bean (Anti-coffee). Normal rabbit serum was used as 'control'.

extra bands representing the multiple green coffee extract-antibody system (Fig. 6). The extra bands observed in this system may well be due to the protein antigens which elicited the PCA reactions in monkeys in the experiments of Layton *et al.*<sup>11</sup>.

Both types of conjugates were antigenically active when tested against rabbit and human antisera by the BDB haemagglutination techniques. Titres ranging from 8,000 to 1,000,000 were obtained with rabbit antisera to both types of conjugates, or to free chlorogenic acid, or to green coffee; titres ranging from 80 to 640 were obtained with human sera from individuals allergic to green coffee. All the haemagglutination reactions could be specifically inhibited with either of the two conjugates.

Conjugates I and II, as well as two newly prepared samples of synthetic chlorogenic acid, produced wheal and erythema reactions on direct intradermal testing in patients allergic to green coffee bean and on passive transfer testing in normal volunteers sensitized with the sera of these patients.

It has been expected in the present series of experiments that *in vitro* (Fig. 2) and *in vivo* (Fig. 3) conjugation of chlorogenic acid with HSA occurs by coupling at the C'5 position on the chlorogenic acid molecule, as demonstrated for similar catechols<sup>12</sup>. To substantiate this assumption and in an attempt to block the reactive position in chlorogenic acid, involved in the coupling with proteins, chlorogenic acid was reacted with diethylamine by the Mannich reaction (Fig. 7). Indeed, the resulting mono-substituted chlorogenic acid derivative, the composition of which was confirmed by elemental microanalysis, failed to elicit wheal and erythema reactions when tested by direct or passive transfer skin testing in humans at concentrations of 10-500 µg/ml. On the other hand, synthetic chlorogenic acid was highly skin active at these concentrations. It may thus be inferred that diethylamine reacted with chlorogenic acid at the same site at which protein conjugation occurs, and that blocking of this site with a monomeric group results in the loss of the ability of

Fig. 7. The product of the coupling reaction of chlorogenic acid with diethylamine by formaldehyde.

chlorogenic acid to become incorporated into a polyhaptenic skin-active protein conjugate.

It might be argued that the purified commercial samples of chlorogenic acid used for the preparation of conjugates or for the immunization of rabbits with free chlorogenic acid might have still contained some 'active' impurities. However, it does not seem likely that this contaminant would have been selectively linked to HSA in the Mannic reaction, or in the reaction catalysed by phenol oxidase, and that antibodies could have been formed exclusively against it. Furthermore, it is inconceivable that antibodies to the hypothetical contaminant would have combined with the synthetic chlorogenic acid leading to the inhibition of the precipitin bands in agar gel.

## EVOLUTIONARY SIMILARITIES BETWEEN PANCREATIC PROTEOLYTIC ENZYMES

By DR. B. S. HARTLEY, DR. J. R. BROWN\*, DOROTHY L. KAUFFMAN and PROF. L. B. SMILLIE†

Medical Research Council Laboratory of Molecular Biology, Cambridge

IT is now generally agreed that the amino-acid sequence of a protein is determined by the nucleotide sequence of its parent gene, so that comparison of the sequences of related proteins can provide clues about their genetic origins. If we compare similar proteins from different species we may hope to trace the evolutionary relationship of the species, since viable mutations which become established in a population will have evolutionary stability, and can act as markers to identify familial resemblances. Comparison of species differences in insulin, haemoglobin and cytochrome *C* have laid the foundation for such studies. However, an alternative approach is to compare different proteins from the same species or individual. Considerable homologies between the amino-acid sequences of these different proteins might indicate a common evolutionary ancestor. For example, certain mammalian peptidases and esterases are distinguished by their capacity to react with diisopropyl phosphorofluoridate (DFP) at a unique serine residue in the active centre. The amino-acid sequence immediately surrounding this active serine residue is remarkably similar in all these enzymes. One hypothesis is that these proteins may have arisen by multiplication of some common ancestral gene, followed by independent mutations to allow divergence of sequence and ultimately of enzymatic specificity. Homologies in their amino-acid sequences would therefore reflect the vestiges of their common ancestor. Alternatively, the similarities in active centre sequence of these serine enzymes might merely represent structures essential for the catalytic activity. In this case they could arise by convergent evolution from genes of different origin. Only if the homologies of sequence were found to be very extensive could this hypothesis be eliminated.

**Sequence homologies in trypsin and chymotrypsin A.** Recent determinations of the complete amino-acid sequence of bovine chymotrypsinogen A (ref. 2) and almost all the sequence of trypsinogen<sup>3</sup> have lent support to the hypothesis of a common evolutionary ancestor. It is instructive to observe that comparison of a few peptides from partial acid hydrolysates of these proteins had originally indicated considerable homology<sup>4</sup>, but further investigation tended to minimize the significance of this<sup>5,6</sup>.

\* Present address: Department of Biophysics, Weizmann Institute of Science, Rehovoth, Israel.

† Present address: Department of Biochemistry, University of Alberta, Edmonton, Canada.

Only when the complete sequences are compared can the true homology be seen<sup>7</sup>, as shown in Table 1, where the structures are so written as to maximize similarities. (A correction (Hartley, B. S., unpublished results) to the sequence of chymotrypsinogen A (ref. 2) is included in Table 1. Positions 212–216 in this sequence<sup>8</sup> should read Ile.Val.Ser.Try and not Ile.Val.Ser.Ser.Try, so that in effect Ser-215 is deleted and the protein contains only 245 residues.) One hundred residues are identical in trypsinogen and chymotrypsinogen A, equivalent to 40 per cent of the sequence, and the homologies occur in blocks of sequence throughout the peptide chains.

One can extend the comparison to include amino-acid side-chains which are chemically similar and may therefore reflect common features in the tertiary structure: for example, lysine and arginine; aspartic and glutamic acid; asparagine and glutamine; serine and threonine; phenylalanine, tyrosine and tryptophan; leucine, isoleucine and valine. On this basis 127 residues are similar or identical, which is 51 per cent of the sequence. This degree of homology is very close to what we find between the  $\alpha$ - and  $\beta$ -chains of human haemoglobin, where 44 per cent of the residues are identical or 53 per cent similar when compared on the foregoing criteria. Yet the haemoglobin chains are remarkably similar both in activity and in tertiary structure. We must realize that trypsin and chymotrypsin have widely different specificities, and one would expect that the evolution of these different activities would accelerate the rate at which mutations could be established in the proteins. The homology between trypsin and chymotrypsin is therefore the more impressive, and might imply that these proteolytic enzymes lie relatively closer in the evolutionary scale to their common ancestor than do the haemoglobin chains, and that some of the homologies reflect elements in the primary structure which contribute to the configuration of the catalytic site but not the specificity site.

**Disulphide bridges of trypsin and chymotrypsin A.** This hypothesis is supported by the evidence of the five disulphide bridges of chymotrypsinogen A (refs. 8 and 9) and the six disulphide bridges of trypsinogen<sup>10</sup>. Radical differences in the order in which the half-cystine residues were linked would imply differences in the configuration of these proteins, whereas similarities might help to define common elements of tertiary structure. A 'diagonal'

paper electrophoretic technique proved very useful for identifying and isolating cystine-bridged peptides from peptic digests of chymotrypsinogen *A* and trypsinogen, and allowed us to determine the bridges shown in Fig. 1.

Four of the five bridges of chymotrypsinogen (Fig. 1, *A*, *B*, *C* and *D*) are exactly homologous in position with four bridges of trypsinogen, and the amino-acid sequence around these four bridges is very similar in both proteins. One bridge of chymotrypsinogen (Fig. 1, *E*) must obviously differ, since the amino terminal half-cystine (Cys-1) of chymotrypsinogen is deleted in trypsinogen and Cys-123 is replaced by serine. Instead, trypsinogen has a neighbouring half-cystine (Cys-129) which forms a different bridge (Fig. 1, *F*). The sixth bridge of trypsinogen (Fig. 1, *G*) is homologous neither in position nor in sequence. We see that the substantial similarities in sequence of trypsinogen and chymotrypsinogen are accompanied by substantial similarities in the disulphide bridges.

**Bovine chymotrypsinogen *B* and porcine elastase.** Are the homologues of sequence and of disulphide bridges found in other pancreatic proteinases? The 'diagonal' paper electrophoretic technique of Brown and Hartley<sup>8</sup> makes the purification of related sets of cysteine acid peptides relatively easy, and by this means we have been able to determine the amino-acid sequence around the five disulphide bridges of bovine chymotrypsinogen *B* (ref. 11) and the four disulphide bridges of porcine elastase<sup>12</sup>.

Chymotrypsinogen *A* and chymotrypsinogen *B* are found together in approximately the same amount in the pancreatic juice of a single cow<sup>13</sup>, and the two zymogens are similarly activated by trypsin to yield chymotrypsins of very similar activity and specificity<sup>14</sup>. Yet the two zymogens differ appreciably in amino-acid composition<sup>15</sup>, so that one is led to suspect gene-doubling, as with the  $\beta$ - and  $\gamma$ -chains of haemoglobin, for example. The amino-acid sequence around the five cystine bridges of chymotrypsinogen *B* is shown in Table 1. We see that, as expected, the homologous sequences are bridged identically to those of chymotrypsinogen *A* (Fig. 1). In this case, the occasional differences in amino-acid sequence are more illuminating. Since the proteins are so similar in activity, it is unlikely that amino-acid side-chains which differ appreciably in chemical character between *A* and *B* play an important part either in the activity or configuration of the catalytic site. In a sense, chymotrypsinogen *B* carries 'built-in chemical modifications' of chymotrypsinogen *A*, so that certain parts of the chain can be excluded from 'the active site'. This applies to residues 128, 136, 138, 168 and 205. Thus, although the Cys-137 to Cys-204 bridge (Table 1, *D*) lies very close to the active centre serine (residue 198), the amino-acid residues adjacent to it can be altered without affecting the activity of the enzyme. The sequence shown in Table 1 accounts for 71 of the 246 residues of bovine chymotrypsinogen *B*. Eight differences in sequence are observed, so that by extrapolation we may expect about 10-15 per cent of the total residues to differ from chymotrypsinogen *A*. Analogy with the evolution of haemoglobins<sup>16</sup> would lead us to conclude that the two bovine chymotrypsinogens lie closer to their common evolutionary ancestor than the  $\beta$ - and  $\alpha$ -chains of human haemoglobin (27 per cent differences) but further than the  $\beta$ - and  $\delta$ -chains (6 per cent).

Porcine elastase is another pancreatic proteolytic enzyme with a different substrate specificity from either trypsin or chymotrypsin<sup>17</sup>. However, it too reacts at a unique serine residue with diisopropyl phosphorofluoridate, and the amino-acid sequence immediately adjacent to this reactive serine is the same as that in trypsin and chymotrypsin<sup>18</sup>. The 'diagonal' disulphide bridge technique has already allowed us to conclude that it has a cystine-bridged histidine sequence homologous to that of trypsin and chymotrypsin, which appears to be a second component of the active centre<sup>18</sup>. We have purified this enzyme, and find that it has four disulphide bridges,

Table 1. AMINO-ACID SEQUENCES OF PORCINE ELASTASE (*E*) AND BOVINE TRYPSINOGEN (*T*), CHYMOTRYPSINOGEN *A* (*CA*) AND CHYMOTRYPSINOGEN *B* (*CB*)<sup>\*</sup>

\* Residues which are identical in any two of elastase, trypsinogen or chymotrypsinogen are underlined. Chemically similar residues are in normal type. Differences are shown in italics. In chymotrypsinogen *B*, residues which differ from chymotrypsinogen *A* are shown in bold type. Disulphide bridges are lettered *A-G* as in Fig. 1. Asx indicates aspartic acid or asparagine and Glx stands for glutamic acid or glutamine. The 'overlap' between residues 188 and 189 of elastase is uncertain.

Fig. 1. Disulphide bridges in bovine trypsinogen and chymotrypsinogen A. The shaded circles indicate amino-acid residues which are chemically similar or identical in the two proteins. The disulphide bridges are lettered A-F as in Table 1. H indicates the two histidine residues and S the serine residue of the active centre. The point of activation by trypsin is shown by a full arrow and broken arrows indicate additional chymotryptic splits which form  $\alpha$ -chymotrypsin. The numbering of residues is as Table 1, and deletions are indicated by lines between the circles.

surrounded by the amino-acid sequences shown in Table 1. Six of the half-cystine sequences (around residues 42, 58, 183, 194, 204 and 223) are clearly homologous with trypsin and chymotrypsin, but the sequences around Cys-137 and Cys-169 show little or no homology. Nevertheless, the similarities in sequence are sufficiently striking to suggest that the four disulphide bridges of porcine elastase are homologous with the four bridges which are common to bovine trypsin, chymotrypsin A and chymotrypsin B.

**Comparison of the four sequences.** In order to maximize homologies, a minimum number of arbitrary deletions have been introduced into the sequences shown in Table 1, so that the numbering corresponds to that of some hypothetical evolutionary precursor. Starting at the amino-terminus, we see that the first homology occurs at residues 15-18, the site of tryptic activation of each of the zymogens. Labouesse *et al.*<sup>15</sup> have concluded that the ionization of the amino-terminal Ile-16 affects the catalytic activity of chymotrypsin, so this residue may contribute to the conformation of the active site. The next notable block of similarities occurs between residues 28 and 58, which includes the 'histidine loop' of all the proteins. It is interesting that, although His-57 is present in the active centre of chymotrypsin, the homologies cease abruptly at Cys-58. The stretch of sequence 74-94 contains fewest homologies, but it is relevant to note that in chymotrypsin this sequence contains six lysine residues, regularly spaced, and all the lysine residues of chymotrypsin can be chemically modified without affecting the enzyme activity<sup>16</sup>. Another impressive block of homologies occurs between Tyr-95 and Ser-114, followed by a group of five residues surrounding the Cys 1-123 bridge of chymotrypsin (Fig. 1, E). As previously mentioned, the amino-terminal cysteine-1 is 'deleted' in trypsinogen and we find that serine replaces half-cystine at position 123 in an otherwise homologous sequence. However, a new half-cystine appears close by in trypsin at position 129 which forms a quite different disulphide bridge with Cys-236 near the carboxyl terminus (Fig. 1, F). Thus in the short section of sequence 123-129 trypsin and chymotrypsin form quite different disulphide bridges while elastase has no bridge at all.

The homologous sequence 132-146 includes one of the 'serine knot' bridges (Fig. 1, bridge D) which surround the active centre Ser-198, and is found in all these enzymes. Then follows a stretch (147-180) in which homologies are intermittent but relatively rare. It is in this stretch that the sixth disulphide bridge of trypsin occurs (Fig. 1, bridge G), having no analogue in elastase or chymotrypsin,

and we are at liberty to postulate differences in tertiary structure in this region. However, Cys-169 is part of bridge B which forms a 'methionine loop' in all the enzymes.

The section from Met-181 to Cys-204 includes the active centre serine sequence. Now that we have an extended sequence from porcine elastase we can see that the homologies are even more impressive than could formerly be concluded. Methionine is a relatively rare amino-acid, and since it occurs at position 181 in homologous sequences in all these enzymes, we may suspect that it plays some part in the common catalytic site. We also see homologies between residues 188-193 which are not otherwise apparent. The point is neatly illustrated by observing that Gln-195 is a feature of both elastase and trypsin, and Leu-202 of elastase and chymotrypsin, while Val-203 is common to trypsin and chymotrypsin. These minor differences may be of special evolutionary and possibly enzymatic interest because they occur so

close to the active centre Ser-198; for example, alkylation of Met-195 causes a decreased binding of chymotrypsin substrates without affecting the turn-over rate<sup>17</sup>. For this reason, we might be tempted to look carefully at residues on the other side of the Cys-194 and Cys-204 bridges which form the 'serine knot'. Homologies around Cys-223 and Cys-137 are less exact, and are therefore less likely to form part of the common catalytic site. We also observe that the homologies cease abruptly at Cys-204, and even chymotrypsinogen A and B differ at position 205. We therefore conclude that the 'serine knot' sequence from Met-181 to Cys-204 together with the 'histidine loop' from Pro-28 to Cys-58 are probably components of a common catalytic site in these enzymes.

Regular blocks of similar sequences extend from here on to the end of the chains. The results so far obtained with porcine elastase allow us to say that of the 77 residues of sequence shown in Table 1, 36 (47 per cent) are identical to comparable residues in bovine trypsin or chymotrypsin, or a total of 43 (56 per cent) show chemical similarity. These homologies of sequence and of disulphide bridging between three pancreatic proteolytic enzymes of widely different specificity point both to a common evolutionary ancestor and to common configurations in their catalytic sites.

## IMPORTANCE OF THE CARBOXYL END OF BRADYKININ AND OTHER PEPTIDES

By PROF. JOHN MORROW STEWART and PROF. D. W. WOOLLEY  
The Rockefeller Institute, New York

THE biological activity of bradykinin as an excitant of smooth muscles can be modified by many kinds of structural alterations in the molecule. The usual finding has been that exchange of one of the amino-acid residues of the hormone for some other reduces but does not destroy the biological action. Thus, exchange of an alanine residue for each residue in turn of the hormone has yielded a series of peptides<sup>1</sup> which still show bradykinin-like actions on smooth muscles, although the potency of all but one of the peptides so obtained is somewhat (and in some cases very considerably) reduced in comparison to bradykinin itself. Many other kinds of structural alteration of the molecule have been examined<sup>1,2</sup>. These investigations show that no one amino-acid residue is essential for biological activity. Indeed, replacements such as alanine for proline in position 3 or glycine for serine in position 6 can be made without changing the biological activity on smooth muscles.

A further feature of the structural specificity of bradykinin has also emerged from these studies. This is that additions can be made to the amino end of the molecule without much loss of biological potency on smooth muscles. Thus, lysylbradykinin (kallidin) and methionyl-lysylbradykinin<sup>1</sup> have almost as much potency as does bradykinin itself, and glycylbradykinin is even more active<sup>3</sup>. Similarly, in our own investigations, acetylbradykinin has shown good activity. It would thus appear that lengthening the molecule at the amino end has only a small effect on potency, at least if the lengthening is not greater than one or two residues.

In contrast to this has been the marked effect of lengthening from the carboxyl end, which is the subject of this article. When just a single amino-acid residue was added to the carboxyl end of bradykinin the potency was markedly reduced.

Although this finding might be of only minor interest if it were restricted to bradykinin alone, it takes on significance when one contemplates the number of biologically active peptides for which the same general phenomenon seems to hold. One begins to ask whether some general principle of importance in understanding the mechanism of action of these important compounds may not reside here. In the cases of angiotensin, gastrin, eledoisin, oxytocin, and even of proteins such as pancreatic ribonuclease, one sees clearly that, just as with bradykinin, the carboxyl end cannot be modified at all, although changes can be made at the amino end (and inside the peptide chain) without serious damage to the biological potency. However, at the outset, an exception must be noted, that is, the case of melanophore-stimulating hormone, for which it is well known<sup>4</sup> that amino-acid residues can be added to the carboxyl end without marked loss of potency. This is clearly shown by the MSH activity of ACTH.

Let us consider, first, the case of bradykinin. The biological activities of the derivatives mentioned at the start of this article have been reviewed elsewhere and tabulated<sup>1</sup> so that the reliability of the generalization made in the first paragraph can be easily verified. The new derivatives of bradykinin, in which amino-acid residues were added at the carboxyl end of the peptide chain, were synthesized by the solid-phase method developed in this laboratory by Merrifield<sup>5</sup>. The tertiary-butyloxycarbonyl (*t*-BOC) derivative of the amino-acid

desired at the carboxyl end of the peptide was esterified to a chloromethylated polystyrene resin. The *t*-BOC protecting group was then removed, as described by Stewart and Woolley<sup>6</sup>, by treatment of the resin with 4 M hydrochloric acid in dry dioxane, and the next amino-acid residue was added to the peptide by means of the dicyclohexylcarbodiimide condensation. The solvent used for this condensation reaction was methylene chloride in all cases except when the *t*-BOC amino-acid residue being added was *t*-BOC-nitroarginine. Because of the low solubility of this amino-acid derivative, the solvent used for that condensation reaction was dimethylformamide. The use of methylene chloride allowed achievement of quantitative yield at each coupling stage with only 2.5 equivalents of each entering *t*-BOC-amino-acid. It was thus to be preferred to the use of dimethylformamide as described by Merrifield in the original synthesis of bradykinin by the solid-phase method.

The completed peptide was liberated from the resin by dry hydrogen bromide in trifluoroacetic acid, and the dinitropeptide so obtained was hydrogenated with the aid of a palladium catalyst supported on barium sulphate. The free peptide was then purified by countercurrent distribution in the solvent system of *l*-butanol and aqueous trifluoroacetic acid.

Each new peptide was obtained as a pure compound which showed a symmetrical peak in countercurrent distribution, a single spot with the expected rate of migration in paper electrophoresis and the expected ratios of amino-acids when hydrolysed and analysed quantitatively according to the method of Moore, Spackman and Stein<sup>7</sup>. The analytical results are summarized in Table 1. The bradykinin-like potency of each peptide was measured with the aid of isolated uterine horns of oestrogenized rats as previously described<sup>8</sup>.

Table 1. NEW ANALOGUES OF BRADYKININ

Compound	Amino-acid ratios found*					
	Gly	Ser	Pro	Phe	Arg	$\Sigma$ †
Bradykinyl glycine	2.00	0.81	2.90	1.96	2.17	1.06
Bradykinyl-L-arginine	1.00	1.08	2.81	1.85	2.00	0.85
Acetylbradykinin	1.00	0.95	3.06	2.14	1.97	3.16

\* Acid hydrolysates were analysed by chromatography (ref. 7).

† Partition coefficient in the countercurrent distribution system *l*-butanol: water: trifluoroacetic acid (60:50:1).

The potencies of several derivatives of bradykinin are shown in Table 2. The derivatives with extra amino-acids at the amino end, namely, lysylbradykinin, glycylbradykinin and methionyllysylbradykinin, were previously known compounds. Acetylbradykinin was synthesized during the course of the present investigation.

Table 2. EFFECT OF ADDED RESIDUES ON BRADYKININ POTENCY

Compound	Activity	Ref.
Bradykinin: Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg	1	1
Lys-Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg	1/2 <sup>a</sup>	1
Met-Lys-Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg	1/3	9
Gly-Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg	3/2	1
Acetyl-Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg	1/3	—
Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg-Gly	1/150	—
Arg-Pro-Gly-Phe-Ser-Pro-Phe-Arg-Arg	1/25	—

The results in Table 2 show that although additions of amino-acid (or acetyl) residues to the amino end of the molecule did not greatly reduce potency, the addition of a single amino-acid residue to the carboxyl end had a marked effect on the potency. An arginine at the carb-

oxyl end did not reduce the activity as much as did an extra glycine, but the effect even of an arginine was marked.

Let us now consider in this light the case of angiotensin. This was perhaps the first case to be seen clearly. Page and Bumpus<sup>18</sup> had observed several years ago that a derivative of angiotensin which was inactive on rat uterus could be found in crude concentrates of angiotensin. This material, angiotensin I, became active when digested with a peptidase which converted it to angiotensin II by removal of a dipeptide from the carboxyl end of angiotensin I. It was thus clear that although angiotensin II was active in causing contraction of the muscle, angiotensin I, which differed from it only in having two amino-acids attached to the carboxyl end, was inactive. Replacement of the C-terminal phenylalanine of angiotensin II by alanine gave an inactive compound. The importance of the structure at the carboxyl end of angiotensin was thus clear. It was also necessary to have it unsubstituted in order to find activity on smooth muscle.

In contrast to this state of affairs, Arakawa *et al.*<sup>11</sup> showed that the amino end of angiotensin need not be free or unaltered. Several residues of *O*-acetyl serine could be added to this end without great loss of potency. Furthermore, angiotensin could be shortened from the amino end by removal of two of the terminal residues without destruction of the biological activity. All these observations showed quite clearly the need for an unnumbered carboxyl end, and the lesser importance of the amino end.

The importance of the carboxyl end of oxytocin has been known for several years. du Vigneaud *et al.*<sup>19</sup> had shown that when the glycine amide portion of the peptide was changed to glycine, and all other parts of the molecule were left undisturbed, all activity was lost. Removal of the entire glycine amide residue or of additional residues from the carboxyl end gave peptides with almost no activity<sup>18</sup>. No derivatives of oxytocin have been made in which the molecule has been lengthened at the carboxyl end, but in the light of present findings with bradykinin, such a manoeuvre would be interesting. Existing results, however, suggest that the carboxyl end must not be modified if high activity is to be retained, not even to the extent of replacing  $-\text{NH}_2$  with  $-\text{OH}$ .

Very recent findings indicate similar results for the two biologically important peptides gastrin<sup>14</sup> and eledoisin<sup>15,16</sup>. The case of gastrin is particularly striking. This heptadecapeptide amide can be shortened from the amino end down to a tetrapeptide amide without marked loss of hormonal activity, but if the carboxyl end is merely changed from the amide to the ester the activity is lost. It will be of great interest to determine whether lengthening the carboxyl end by addition of an amino-acid residue (or more particularly, by addition of an amino-acid amide residue) will also result in inactivation.

The situation with eledoisin is quite similar to that of gastrin. The natural peptide, which is an undecapeptide amide, can be shortened from the amino end down to a hexapeptide amide without great loss of potency, but the intact structure of the carboxyl end seemed to be necessary for biological activity. Exchange of the methionine amide at the carboxyl end of the peptide for the corresponding methionine dimethyl amide destroyed activity, although drastic exchanges of residues could be made in the region of the molecule toward the amino end without significant effect. How little was the importance of electrostatic charge for biological activity could be seen from some of these analogues in which amino-acids with extra ionized groups were replaced by ones with no ionic charge. Thus, the elimination of the lysine residue in position 4, the aspartic acid residue in position 5, or both, caused no serious loss of potency even though great changes had thus been made in the electrostatic charge of the molecule.

Even among the proteins one begins to find evidence of the prime importance of the carboxyl end of the peptide chain. Consider, for example, the case of pancreatic ribonuclease. Potts *et al.*<sup>17</sup> have indicated that the removal of four residues or even of a single residue from the carboxyl end of the enzyme reduced or eliminated its activity. In contrast, the removal of the lysine residue from the amino end of the enzyme and even the addition of polyalanyl groups to all the amino groups<sup>18</sup> did not seem to destroy activity. The results of Finn and Hofmann<sup>18</sup> with the *S*-protein and synthetic portions of the *S*-peptide show that 7 amino-acid residues can be removed from the interior of ribonuclease without complete loss of enzymatic activity.

Additional confirmatory evidence is seen in the cases of insulin and aldolase. When a single amino-acid (asparagine) is removed from the C-terminus of insulin along with the alanine from the C-terminus of the other peptide chain of the protein, the hormonal activity is greatly diminished<sup>20,21</sup>. In the case of aldolase, the ability to bind substrate prior to enzymatic hydrolysis requires the presence of the C-terminal tyrosine residue<sup>22</sup>.

As mentioned near the beginning of this article, MSH and its relative ACTH constitute exceptions to the idea under discussion. Although exceptions are a cause for concern, the considerable number of cases which seem to show the importance of the carboxyl end of peptides has caused us to consider the situation worthy of attention. In connexion with these exceptions, the case of the *S*-peptide of ribonuclease may be noteworthy. Seven amino-acid residues can be removed from the carboxyl end of this peptide before its activity in being able to reconstitute the active enzyme is completely lost. By contrast, as we have just seen, not even a single amino-acid can be removed from the carboxyl end of the entire enzyme without great loss of activity. If MSH were to function biologically (as Hofmann has suggested) by combination with a large 'incomplete' enzyme, just as does the *S*-peptide of ribonuclease, the failure of MSH to conform to the generalization explored in this article might become more understandable.

As yet there seems to be no adequate reason to explain why the carboxyl end of peptides should be of great importance. Woolley *et al.*<sup>23</sup> have suggested that in chymotrypsin the centre which specifically attracts the substrate to the catalytically active site of the enzyme (the so-called specificity centre) is the tyrosine residue at the carboxyl end of one of the peptide chains, but direct proof of this view is lacking.

## MYXOMATOSIS AND THE RABBIT FLEA

By THE HON. MIRIAM ROTHSCILD

Ashton, Peterborough

IN a recent article in *Nature*<sup>1</sup>, P. J. Chapple and N. D. Lewis show that the myxoma virus can survive on the rabbit flea (*Spilopsyllus cuniculi* (Dale)) kept underground without a host for 105 days and still be capable of infecting a rabbit with the disease. This had been assumed without any definite evidence since 1956, when Shanks, Allan and Brown<sup>2</sup> demonstrated that 50 days after the last rabbit in a flea-infested warren had died, other rabbits became infected with myxomatosis when introduced into the warren. It was also known<sup>3</sup> that the myxoma virus remained infective for 220 days on the mouth-parts of mosquitoes which had fed on myxomatous hosts. Furthermore, Allan<sup>4</sup> recorded that unfed rabbit fleas can survive 9 months in a refrigerator at approximately 4°C—an observation corroborated by me<sup>5</sup> for the fed flea—and therefore it was evident that a cold winter passed without the presence of the host would be unlikely to kill off all 'free' fleas in burrows. It is also known that the rabbit flea may survive at least a year on the captive host<sup>4,6</sup>.

The puzzle, therefore, concerning the reappearance of myxomatosis in areas apparently free of the disease centres for periods of more than a year, rather than relatively short periods such as 105 days. In northern Africa it has recently been shown<sup>7</sup> that ticks are among the principal vectors of myxomatosis and it has previously been suggested by several observers that these relatively long-lived vectors might play an unobtrusive part in the spread of the disease in Britain, and possibly account for the reappearance of myxomatosis in areas free of the disease for long periods. About two years ago it was noted<sup>8</sup> that both in northern France (Pont l'Évêque, Normandy) and in England (Ashton, Peterborough), fresh outbreaks of myxomatosis, in areas where the disease has apparently been absent for more than a year, followed quickly on the introduction of flocks of sheep from elsewhere into the areas in question. Allan (personal communication) has made similar observations in Scotland, where the movements of cattle (which also harbour ticks) as well as sheep were involved. In Northamptonshire ticks are not very common on either rabbits or hares; but they frequently parasitize hares and to a lesser extent rabbits in Scotland (from where the sheep at Ashton were obtained) and France, and Allan<sup>6</sup> has recently found that ticks are one of the predominant groups of ectoparasites on the rabbit in Spain (Coto Donaña). Furthermore, Allan and Shanks<sup>9</sup> noted that ticks can transmit the disease in the laboratory. One batch collected in the wild in Scotland was infected with the virus since rabbits injected with these ticks (after grinding up in a pestle) developed myxomatosis<sup>4</sup>. It therefore seems quite possible that both sheep and cattle could pick up infective ticks and thus act as transport hosts for these vectors; information concerning the survival time of the myxoma virus in and on these arthropods would therefore be of considerable interest.

The most perplexing aspect of the epidemiology of myxomatosis in Britain and northern France at the present time is the recent rise of the rabbit-flea index on the hare<sup>10</sup>. Consequently—since the rabbit flea now has an alternative host, if only a transport host—the pertinent question to-day is not how long will the myxoma virus survive on the 'free' vector, separated from the dying or dead myxomatous rabbit, but rather how long will it survive on and in a vector feeding on another host.

In the past the rabbit has been considered the only true host of the rabbit flea in Europe, and the hare regarded merely as an accidental host<sup>11</sup>; but this may have been

a false impression due to the fact that it was a much less favoured host and the flea was present on it in relatively small numbers. Certainly to-day there appears to be a very general infestation of the hare both in northern France<sup>6</sup> and in Britain, and in at least one area at Ashton the rabbit-flea index on the hare rose temporarily, in 1964, above that of the rabbits in the same habitat. There is, however, no proof that the rabbit flea is capable of breeding successfully on the hare, and adapting itself to the different hormone cycle of this host or its surface nest, although the presence on the lactating female of gravid female fleas, and fleas which have been fertilized and have laid eggs<sup>12</sup>, is highly suggestive.

Despite its extreme specialization the rabbit flea is nevertheless capable of considerable adaptation and its habits are not identical throughout its range. LeGac<sup>13</sup> directed attention to the fact that in the forest of Bosen (Var), France, he only found *S. cuniculi* extremely rarely on the body of the host and that it was confined to the burrows of the rabbit. Collado<sup>12</sup> recorded it on the rabbits' ears in Spain, but Allan<sup>6</sup> has recently confirmed that in the summer on the Coto Donaña this species was only present in burrows and not on the body of the host as it is in northern Europe; furthermore, three species of fleas infect the rabbit in Spain. Preliminary experiments with rabbit fleas collected on Herm (Channel Islands) suggest that some populations vary considerably in their response to mammalian hormones. Thus the rabbit flea collected at Ashton responds by maturation to five daily injections into the host (the 8-lb. New Zealand White buck rabbit of 0.01–0.30 mg of hydrocortisone ('Hydrocortisyl'; Roussel Laboratories)<sup>14</sup>, but those collected on Herm require five daily injections of 0.10–0.80 mg to elicit a similar response.

If in fact the rabbit flea is capable of breeding on the hare, the increase in numbers of this host, which has recently been reported in many localities in Britain, would favour a rise in the flea index<sup>14</sup>. Until larval or pupal stages are demonstrated in the 'form' or nest of the hare, it cannot be ruled out that all the fleas found on adult hares (which may number 100 or more per individual) have been acquired by these animals moving about in areas where fleas have abandoned their true hosts dying from myxomatosis. The extraordinary ability of the rabbit flea to attach itself to a passing host when 'free' on pasture has been admirably demonstrated experimentally by Mead-Briggs<sup>15</sup>. The tendency of this flea to transfer from one host to another, not necessarily its own host, if there is contact between two individual animals has also been demonstrated experimentally<sup>16</sup>.

The hare itself at the present time apparently rarely contracts myxomatosis<sup>17</sup>, or if it does so, the disease must generally follow a benign and unobtrusive course in this animal, since it is rarely noted. It seems not impossible, however, that through constant inoculation by infected fleas a strain of myxoma virus adapted to survival in the hare will eventually be evolved. Fleas, therefore, passing on to the hare from infected rabbits will not prove fatal to their host and will survive as potential vectors; it is for this reason that the emphasis has passed from the infective 'free' vector, skulking in burrows or on the ground, to the widely disseminated infective vector feeding on the hare. Some parasites such as the plague bacillus damage the vectors and it was early recognized that many fleas which have ingested *Pasteurella pestis* do not live as long as uninfected fleas<sup>18,19</sup>. So far there

is no evidence that the myxoma virus multiplies in the rabbit flea<sup>1</sup> or that the virus itself is damaging to the flea, but there is evidence that fleas feeding on rabbits with myxomatosis are seriously affected by the course of the disease in the host. Thus the majority of such fleas undergo maturation of their ovaries<sup>14</sup>. This may be due to a hormone imbalance in the rabbit or to the high blood temperatures of the host directly attributable to the disease. In Nature, maturation of the rabbit flea on the normal pregnant host and new-born young is not associated with rises in temperature of the host; nevertheless it has recently been found<sup>6</sup> that a sudden large rise in the ear temperature of rabbits (10°–14° F) will stimulate increased defecation rate in rabbit fleas feeding on them. The increased volume of blood passing through the flea thus automatically increases the amount of corticosteroid hormones ingested by the parasite which in turn can stimulate ovarian development. In any event, the fleas feeding on rabbits suffering from myxomatosis not only display yolk production in the developing oocytes, but also other changes associated with maturation, such as overall increase in the size of the gut, proliferation of the cells lining the gut, hypertrophy of the salivary glands, depletion of the fat body and a somewhat 'ragged' appearance of the internal organs often characteristic of the spent or aged flea. It therefore seems highly probable that infected fleas in Nature which have spent about a week on the diseased host will not survive so long as uninfected fleas on healthy hosts or as Dr. Chapple's fleas<sup>1</sup> which fed for a short period on a rabbit suffering from myxomatosis and were then removed from the host and sunk in tubes in the ground.

The most striking aspect of myxomatosis in Britain to-day is the rapidly changing evolutionary nature of the situation. Both here and in Australia attention has been chiefly centred on the rabbit and the virus. Thus it has been shown that various avirulent strains of the virus have developed in less than a decade<sup>21</sup>, and the rabbit is now suspected of increased resistance, which was the most striking feature of the Australian scene<sup>22</sup>. It was early realized by Sir Christopher Andrewes that the course of myxomatosis in Britain could be modified by the

presence of a successful host-specific vector which was absent in Australia, a situation which would probably favour the survival of a more virulent form of the virus. In this case it would appear probable that the selective pressures on the flea would be simultaneously increased and evolution would inevitably proceed in the direction of poor vectorship. The fact that the rabbit flea responds by maturation on the diseased host, and has also found a widely distributed alternative host—even if it is only a transport host—indicates two lines along which selection could operate. Myxomatosis can therefore be expected to mould the vector as well as the host and the virus. In any event, in this complex and interesting triangle, selection pressures must be exceedingly high and we are thus presented with an unusual opportunity for studying the evolution of a vector.

## EFFECT OF INHIBITION OF RNA SYNTHESIS ON NEURAL INFORMATION STORAGE

By DR. STANLEY H. APPEL\*

Duke University Medical Center, Durham, North Carolina

FOR many years scientists have been intrigued with the problem of how information can be stored within the nervous system. The investigations of Hebb<sup>1</sup> directed attention to the synapse as the site where communication between neurones could be potentially modified by the learning process. This theory recognized behaviour as being determined by the communal response of neurones the random and defined pathways of which interact with each other in a complex fashion. Short-term memory would be explained by short-term changes at the synapse activated by reverberating circuits, and long-term memory by permanent changes at the synapse permanently altering intercellular communication. With the recent advances in molecular biology and the advent of newer biochemical techniques, attention has been directed to nucleic acid macromolecules, specifically RNA, as the site for long-term information storage within the nervous system<sup>2,3</sup>. Each new memory trace would be defined by a new RNA macromolecule which would persist so long as the memory trace persisted. The role of the synapse

and of intercellular communication becomes of lesser significance in this theory, and accordingly, attention is directed to the RNA changes within a single cell, or groups of cells, without considering their effect on one another.

It is clear from the experiments of Hyden<sup>4</sup> and Brattgard<sup>5</sup> that neuronal RNA may change within the central nervous system under a variety of experimental situations. However, it is not clear that such changes in RNA necessitate a theory which defines the engram in terms of a single macromolecule. Dingman and Sporn<sup>6</sup> demonstrated that 8-azaguanine, a nucleic acid antimetabolite, diminished the ability of rats to manoeuvre correctly their way through a new swimming maze, although it had no effect on performance in a previously learned maze. However, it is not clear to what extent normal production and function of RNA were altered by the presence of the 8-azaguanine, and to what extent the demonstrated effect on learning was the result of the new 8-azaguanine-containing RNA species, the lack of normal RNA associated with the learning experience, or some other less-direct effect on cellular metabolism. Chamber-

\* Present address: Departments of Medicine and Neurology, University of Pennsylvania, Philadelphia, Pennsylvania.

lain *et al.*<sup>7</sup> were unable to confirm an effect of 8-azaguanine in rats running a Hebb-Williams maze, although they were able to prolong the latency time for 'fixation' of an asymmetric limb-posturing by administration of 8-azaguanine. In these experiments there are no data to indicate what biochemical effects the antimetabolite had produced. Barondes and Jarvik<sup>8</sup> were able to inhibit the synthesis of mouse brain RNA by intracerebral injection of actinomycin *D* but were unable to affect performance of a learned response.

These experiments using nucleic acid antimetabolites and the data to be presented here using actinomycin *D* to block synthesis of RNA associate changes in RNA with changes in certain aspects of behaviour. The question raised by this article is whether such data unequivocally support the role of RNA as the molecular engram, or whether these data can be interpreted to support the previously accepted 'synaptic theory'.

*O57/BL8* male mice weighing 15–20 g were injected intracerebrally with 20- $\gamma$  (in 20  $\mu$ l.) actinomycin *D* (solubilized with mannitol) and were compared with mice similarly injected with 800- $\gamma$  (in 20  $\mu$ l.) mannitol as described by Barondes and Jarvik<sup>8</sup>. At 18–24 h there were no discernible differences in motor activity either inside or outside the cage, although with the doses used all the animals were dead by 96 h. At 18 h after injection the mice were tested in several different situations. The first task was a novelty activity test in which the mice were placed in a box with a black or white knob in one corner. After 15 min in their cages they were returned to the box where either the same or a novel knob stimulus was presented. The latency of approach and the time in contact with a novel object were recorded and compared with similar measurements recorded when the knob was not changed. In both the actinomycin and the mannitol groups there was a significantly reduced latency until contact with the novel object and a lengthened period of contact with it. There was no difference between the two groups in their performance.

A second group of mice similarly injected with actinomycin *D* or mannitol was tested on the acquisition or retention of skill in a swimming maze. A T-maze was used with the central channel painted grey, one of the arms painted white, and the other black. An escape ladder was always located at the end of the white arm and its position as a right or left turn was altered on a random basis. Mice which were injected, as well as those which were not, required approximately 30–40 trials to reach 80–90 per cent criterion with an error being considered any time a mouse turned away from the ladder. This level of performance could be maintained for longer than one week without additional training. Sixteen animals injected with 20- $\gamma$  actinomycin *D* and 16 animals injected with 800- $\gamma$  mannitol, and tested 18 h post-intracerebral injection, made approximately the same number of errors in the first 10 trials in learning the maze (Table 1A). Similarly, no effect of actinomycin *D* could be demonstrated on the retention of this swimming maze performance, either in errors made or in time necessary to swim the maze (Table 1B).

Table 1

## (A) Acquisition of swimming maze performance

Injection	No. animals	Total trials	Total errors
Mannitol	16	80	46
Actinomycin	16	80	48

Animals were tested 18 h after intracerebral inoculation of 20  $\gamma$  (20  $\mu$ l.) of actinomycin *D* and 800  $\gamma$  (20  $\mu$ l.) of mannitol. They were given 5 trials in the swimming maze, and their performance on trials 6–10 was recorded. The errors on trials 1–5 were also comparable in the two groups.

## (B) Retention of swimming maze performance

Injection	No. animals	Trials	Errors	Time/trial
Mannitol	23	69	14	6 sec
Actinomycin	23	84	17	7 sec

The animals were trained to 90 per cent correct responses by 30–40 trials in groups of 10 trials over 3 days. They were rested 1 day and were inoculated as in (A). They were tested 18 h after injection and approximately 45–48 h after their last trial.

Table 2. LATENCY OF RESPONSE IN JUMPING BOX  
(In sec  $\pm$  S.E.)

Drug	No. animals	1	2	3	4	5
Actinomycin	23	52 $\pm$ 2	25 $\pm$ 4	30 $\pm$ 6	32 $\pm$ 4	24 $\pm$ 4
	Percentage	100	66	57	60	64
Mannitol	23	35 $\pm$ 3	9 $\pm$ 2	7 $\pm$ 1	6 $\pm$ 1	5 $\pm$ 1
	Percentage	100	26	20	17	14

The 51 animals which were tested for retention of swimming maze manoeuvrability were then tested for their ability to jump up 2.5 in. on to a ledge from a grid floor when a shock was passed through the grid. The animals were removed from the box if they had not escaped to the ledge after 60 sec of shock. The trials were spaced 10 min apart. As can be seen in Table 2, there was a definite difference in performance of the actinomycin-injected animal compared with the mannitol-injected animal. This difference in performance was present even in the first trial. Furthermore, the mannitol-injected mice were able to improve their performance so that the latency on the last trial represented 14 per cent of the initial trial, whereas the actinomycin-injected animals had a latency on the fifth trial of 64 per cent of the initial one. This behavioural change was not clearly related to motor weakness because all animals were able to jump and demonstrated no generalized motor defects. It seems more likely to be associated with a defect in the neural interpretation or with a response to the shock applied. Furthermore, when the mice were returned to the swimming maze, accuracy in swimming the maze and the ability to traverse it in less than 10 sec were preserved in the actinomycin as well as in the mannitol-injected animal.

The extent of inhibition of RNA synthesis was evaluated in 10 of the tested *O57/BL8* animals and in 10 *CF* strain white mice, which had not undergone behavioural tests. Orotic acid 6- $^{14}$ C was injected intracerebrally into animals 18 h after receiving 20- $\gamma$  actinomycin *D* or the corresponding mannitol inoculation. Since the incorporation into RNA appeared linear for at least 60 min in control experiments the brains were removed after 45 min, homogenized, and processed in two ways. In one group of animals, RNA was isolated by the hot phenol technique of Scherrer and Darnell<sup>9</sup>; in another group, it was characterized by alkaline hydrolysis of an acid precipitate according to a modification of the technique of Schmidt and Thannhauser<sup>10</sup>. Both techniques demonstrated significant inhibition of RNA synthesis in the actinomycin-injected animals compared with the mannitol-injected ones (Table 3). The degree of inhibition was the same in both strains of mice, and was more marked in the brain stem and sub-cortex than in the cortex.

Although it is probable that these experiments demonstrate an alteration of escape behaviour due to a drug which inhibits RNA synthesis, it is still not possible to make a definitive statement about the role of RNA in

Table 3. INCORPORATION OF ISOTOPES INTO RNA

## (A) Alkali digestion

	Mannitol Specific activity (c.p.m./O.D. at 260)	Actinomycin Specific activity (c.p.m./O.D. at 260)	Inhibition (per cent)
Cortex	326	114	65
Subcortex	345	46	86
Brain stem	380	30	94
Cerebellum	231	61	73

Twelve animals were injected intracerebrally with 2.0  $\mu$ Ci orotic acid 6- $^{14}$ C (0.5 mCi/mole) 18 h after receiving mannitol or actinomycin *D*. Forty-five min later they were killed. The cerebellum was removed, the mid-brain sectioned at the colliculi, and the subcortex scooped out. The tissues were processed by the procedure of Fleck and Munro<sup>11</sup> and the resulting nucleotide solution counted in Bray's solution in a scintillation counter with an overall efficiency of 14 per cent. RNA was estimated at 260 m $\mu$  in a Beckman DU spectrophotometer.

## (B) Phenol extraction

	Mannitol Specific activity (c.p.m./O.D. at 260)	Actinomycin Specific activity (c.p.m./O.D. at 260)	Inhibition (per cent)
Brain	1,190	480	60

Eight animals were injected as in (A) and the entire brain processed according to the method of Scherrer and Darnell (ref. 9). The final RNA solution was counted in Bray's solution with an overall efficiency of 65 per cent.

central nervous system functioning. Of the three tasks tested, performance in only one was affected by the drug. Both acquisition and retention of swimming maze behaviour remained unimpaired and this might seem contrary to RNA playing a part in such tasks. On the other hand, the administration of shock to actinomycin-injected animals definitely interfered with escape behaviour in the jumping box.

Even if it is assumed that the radioactive tracer is a reliable index of RNA synthesis, the demonstration of decreased incorporation of radioactive precursors into RNA associated with an alteration in an animal's response still does not explain what function the RNA serves. RNA is present in all cells, and its synthesis and metabolism are important in cell function. Interference with normal RNA synthesis would then be expected to interfere with cellular metabolism; and one cannot separate injury to RNA as the seat of the memory trace from injury to RNA as a vital constituent in intracellular metabolism which will, in time, affect intercellular communication and the input, storage, or read-out stages of the memory process.

In all the previously described experiments including my own, there seems no way to distinguish between molecules altered in number or quality, and cells so altered. The possibility should seriously be considered that the experiments have been merely chemical ablation studies in which certain groups of cells have been affected which can concentrate the antimetabolite and inhibitor or are especially sensitive to it. Such an interpretation would be suggested by the fact that performance of several behavioural tasks was unaffected and only one behavioural task was altered when 60-70 per cent of RNA synthesis was inhibited. This would also be suggested by the experiments of Flexner *et al.*<sup>11</sup> where interruption of avoidance behaviour was associated with inhibition of protein synthesis by puromycin, and the injection of the drug into the vicinity of the hippocampus and temporal lobe was of paramount importance. Furthermore, in my own experiment, the twisting and writhing movements, staggering, abnormal respiration and rapid loss of responsiveness, which lead to death in 48-96 h after injection of actinomycin D, reflect the disturbed subcortical and brain-stem function. Histological examination of the brains of the experimental and control animals demonstrated injury primarily to neurones with nuclear swelling and loss of morphology throughout the nervous system of the actinomycin-injected animals, especially in the hippocampus, and brain stem (Fig. 1). This finding is in accordance with the greater inhibition of isotope incorporation in the sub-cortex and brain stem than in the cortex itself. However, it does not allow us to decide whether these areas are especially sensitive to the drug or whether they have been merely exposed to a higher concentration.

The unique role of RNA as the engram cannot be deduced solely from experiments which associate increases or decreases in RNA concentration with altered behaviour. That RNA levels vary under different conditions of stimulation is unequivocal, but the question of how such changes are brought about, how long they last, and what functions they may serve are unanswered at present. In the experiments of Hyden, for example, the increased levels and altered base compositions of RNA have been specifically associated with involvement of the RNA as an engram in a 'learning situation'. The probability exists, however, that both in the reported 'balancing' experiment<sup>12</sup> and the more recently published 'transfer of handedness' experiments<sup>13</sup>, the results reflect differences in the extent and pattern of activation of affected cells rather than different situations of 'learning' and 'non-learning'. Our problem is still, then, unresolved. There is no evidence for the synthesis or presumed permanence of an RNA unique to a particular situation. We must still explain how cells may 'interact' and specifically how

Fig. 1. Methyl green, pyronin stain of hippocampal neurone somas ( $\times 700$ ). (A) 24 h post inoculation of mannitol. (B) 24 h post inoculation of 20  $\gamma$  actinomycin D. The nuclei are swollen with loss of substructure (RNA). Feulgen stain for DNA of similar sections shows only the minimal swelling, but no loss of DNA substructure.

previous experience may facilitate transfer of intercellular information.

In essence, any chemical changes which would affect the synthesis or release of neurotransmitter, its affinity for the post-synaptic receptor, its rate of destruction, the post-synaptic membrane properties, or the nature of the post-synaptic cytoplasm and its ability to propagate a depolarization to the initial axon segment might alter intercellular communication and information transfer. The maintenance of these biochemical changes and of the new pattern or level of intercellular communication need not depend on the indestructibility of any single macromolecule. What would be required is that the new steady state of these biochemical alterations be maintained. Activity could induce or 'derepress' gene expression and lead to transient or sustained alterations in RNA and protein metabolism. This may, in turn, facilitate activity by modifying impulse transmission at a subsequent input or output, and thereby reinforce the biochemical changes which initially produced it. The altered pattern of intercellular communication would not then reside in any permanent macromolecular engram but in the dynamic interaction of a post-synaptic cell with its pattern of pre-synaptic influences. This more effective intercellular communication might depend on the duration of the effective biochemical changes and on the time between an initial and subsequent activation of the pathways involved.

No single component could be omitted for effective operation; and the engram would not be defined as resid-

ing in any single molecule or within any single cell. It would be most adequately defined by the interaction of several neurones, and would be most fruitfully explored by investigating the effect of electrical activity on the biochemical state and the effect of the altered biochemical state on subsequent electrical activity.

I thank Drs. John Fuller, Richard Wimer, and Lincoln Clark for their help in the psychological tests used. This work was initiated while I was a visiting scientist at the Jackson Laboratories, Bar Harbor, Maine, and a research associate in the Laboratory of Molecular Biology, National Institute of Arthritis and Metabolic Diseases, Bethesda, Maryland.

'Lyo' meractinomycin (actinomycin D) was kindly supplied by the Cancer Chemotherapy Branch, National Institutes of Health.

This work was supported in part by a grant from the U.S. Public Health Service (A-01391-09).

## 19S ANTIBODY PRODUCTION AGAINST SOLUBLE LIPOPOLYSACCHARIDE ANTIGENS BY INDIVIDUAL LYMPHOID CELLS IN VITRO

By GÖRAN MÖLLER

Department of Tumour Biology, Karolinska Institutet Medical School, Stockholm 60, Sweden

RECENT methods<sup>1-3</sup> have greatly facilitated the detection of cellular antibody production *in vitro*. Antibody synthesis by individual cells has been made visible by mixing immune lymphoid cells with the antigen (sheep red cells) in a semi-solid agar medium; after the addition of complement, each antibody-producing cell is surrounded by a clear plaque of lysed red cells against the background of intact cells. The plaque-forming cells (PFC) have been shown to produce large molecular 19S antibodies; the marked increase of 7S antibodies occurring 5-6 days after the antigen stimulation does not result in detectable plaque-formation. On the contrary, the time of increase of 7S antibodies coincides with the decrease of PFC<sup>4</sup>. The negative influence of 7S antibodies on the appearance of the PFC was emphasized by the finding that passively transferred 7S antibodies specifically inhibited the development of the PFC<sup>5</sup>, suggesting that active synthesis of 7S antibodies might inhibit cellular 19S antibody production.

I have made unsuccessful attempts to detect individual antibody-producing cells *in vitro* with red cell antigens from various species (with the exception of cattle erythrocytes, which cross-reacted completely with sheep red cells) and different serum protein antigens adsorbed on to red cells. However, positive results were obtained in the present work with bacterial lipopolysaccharide antigens adsorbed on to sheep red cells. This report is concerned with the immune response against such antigens as revealed by serum antibody production and development of PFC *in vitro*.

The agar plaque-technique was used as described by Jerne<sup>1</sup>. Lymphoid cells to be tested for antibody production *in vitro* were usually taken from the spleen, but in certain experiments they were also taken from lymph nodes, thymus and peripheral blood. 0.1 ml. of the cell suspension was mixed at 45° C with 2 ml. 0.7 per cent agar containing 1 mg DEAE dextran (Pharmacia, Sweden) and  $4 \times 10^6$  sheep red cells coated with the lipopolysaccharide (obtained from *E. coli* 055:B5). The mixture was poured out on to Petri dishes containing a layer of 1.4 per cent agar and incubated for 1 h at 37° C. Thereafter, 2-3 ml. of a 1/10-1/15 dilution of freshly reconstituted lyophilized guinea-pig complement (Sclavo, Italy) was added to each plate and incubation was continued for 30 min at the same temperature. Reading of the plates was facilitated by staining with benzidine as described by Jerne<sup>1</sup>. Three mice were used for each

determination and at least two agar plates were prepared from each cell suspension. A number of different specificity controls were also included. In each experiment non-immune spleen cells were tested against polysaccharide-coated sheep red cells. In addition, specifically immunized lymphoid cells were tested against non-coated red cells, and spleen cells from animals immunized against a non-cross-reacting polysaccharide (from *Salmonella typhosa* 0901) were mixed with red cells sensitized with *coli* polysaccharide. These controls usually showed a low number of PFC (0-100). There was no increase after immunization with the non-cross-reacting polysaccharide, but the values were usually slightly higher against specifically sensitized red cells than against uncoated cells. It seems possible that this background activity is due to the added effect of 'natural' antibody synthesis against both the sheep red cells and the polysaccharide.

The polysaccharides used for coating the sheep red cells were obtained from Difco, Detroit, and were extracted from *E. coli* 055:B5 by the method of Westphal<sup>6</sup>. A solution containing 1 mg polysaccharide per ml. in saline was boiled for 1 h immediately before use and 0.2-1.0 ml. was added to 0.1 ml. packed and washed sheep red cells. The cells were incubated for 30 min at 37° C, washed three times in saline and diluted to a concentration of  $4 \times 10^6$  per ml. Mice were immunized by the intraperitoneal injection of 0.0025-0.1 ml. of isologous red cells coated with lipopolysaccharides or, in a few cases, with a bacterial vaccine.

Simultaneously with the determination of the number of PFC the humoral antibody response of the same animals was examined by haemolytic and agglutination tests. For haemolysis 0.2 ml. serum was serially diluted in BSS and 0.1 ml. of a 2 per cent sheep red cells suspension coated with the *coli* antigen was added to each tube, followed by 0.1 ml. of guinea-pig complement diluted 1/40. The same lot of guinea-pig complement was used in all experiments. The tubes were incubated for 1 h at 37° C and the last tube showing 100 per cent lysis was taken as the end point. Normal serum controls were tested in parallel; they very rarely gave rise to 100 per cent lysis, and only in titres ranging from 1/5 to 1/40. The agglutination test was performed by mixing equal volumes (0.025 ml.) of antibodies serially diluted in 1.5 per cent polyvinyl-pyrrolidone (PVP) and a 2 per cent suspension in BSS of antigen-coated red cells. After

incubation for 1 h at 37°C the tubes were read as described previously<sup>7</sup>.

Immunization of mice of various genotypes with the lipopolysaccharide antigens from *E. coli* resulted in a rapid increase of the number of plaque-forming spleen cells. Already after 24–48 h the number of PFC started to increase exponentially and continued for 3–5 days. After the peak there was a rapid decline, but background level usually was not reached even after 16 days after immunization (Fig. 1). The development of the PFC thus followed the same pattern as previously described for sheep red cell antigens<sup>1,4</sup>. A second injection with antigen-coated isologous mouse red cells after 16 days stimulated an exponential increase of the number of PFC as in the primary response, but the maximum number of PFC was considerably lower (Fig. 1).

The development of PFC against sheep red cells was previously shown to parallel closely the production of 19S serum antibodies, whereas there was an inverse correlation to 7S antibody synthesis<sup>4,8</sup>. Analogous investigations were performed with the polysaccharide antigen. As demonstrated in Fig. 1, the development of haemolytic antibody titres paralleled the increase of the number of PFC during the first 4 days. Thereafter, the number of PFC started to decrease, whereas the haemolytic antibodies continued to increase for 2–5 days and then reached a steady state for 3–5 days. Agglutinating antibodies followed the same pattern. Thus, there was a clear-cut difference between the kinetics of the immune response measured by the appearance of PFC and humoral antibodies, respectively. A discrepancy between the production of PFC and serum antibodies has been observed previously with sheep red cells, but in that case haemolytic and agglutinating antibodies behaved differently; the increase of 7S agglutinins started at the same time as the increase of the number of PFC, whereas haemolytic 19S antibodies paralleled the PFC<sup>4</sup>. The question whether a similar mechanism operated with the polysaccharide antigen at present used was therefore investigated. Sera from mice immunized with polysaccharide were separated into 19S and 7S fractions by 'Sephadex G-200' gel-filtration and the different fractions were tested for haemolytic and agglutinating activity against antigen-coated sheep red cells. It was regularly found that antibodies occurred only in the 19S fraction, both with regard to haemolytic and agglutinating activity (Fig. 2). Even sera from mice immunized four times with the antigen adsorbed on to red cells or incorporated into Freund's complete adjuvant contained only 19S antibodies. The possible contamination of the 19S fraction with 7S antibodies was excluded by treating whole hyperimmune sera with an equal volume of 0.2 M mercaptoethanol for 30 min at 37°C. This treatment selectively inactivates 19S antibodies and it reduced the agglutinin titres of several sera taken at different intervals after immunization from 1/40,000–1/820,000 to less than 1/5. It would appear, therefore,

Fig. 1. Development of plaque-forming spleen cells and haemolytic antibodies in A.SW mice after immunization with isologous red cells coated with *E. coli* 065 : B6 lipopolysaccharides. Each point represents the mean value from three mice. The arrows indicate the time of antigen injection. ●, Plaque-forming cells; ○, haemolytic serum titres.

Fig. 2. Results of fractionation of a hyperimmune mouse anti-*E. coli* 065 : B6 serum by 'Sephadex G-200' gel-filtration and subsequent determinations of the haemolytic and agglutinin titres of the various fractions. —, Protein concentration; ○, haemolytic titres; ●, agglutinin titres.

that the polysaccharide antigen used stimulated 19S antibody production exclusively. Thus, the discrepancy between the kinetics of PFC and humoral antibodies in this system cannot be ascribed to the production of 7S antibodies.

The possibility that the prolonged presence of 19S antibodies in the sera of immunized animals was caused by accumulation of previously synthesized antibodies was shown to be improbable by the demonstration that the half-life of passively transferred antibodies was very short (6–10 h). It follows that the antibodies present in the sera of the mice are to a great extent newly synthesized.

A further problem investigated was the question whether antibody production occurred in extra-splenic lymphatic organs. It seems possible that cellular antibody formation occurs predominantly in the spleen during the first 4 days after immunization, but is later transferred to other organs, and this would be responsible for the increasing titres of serum antibodies. Extra-splenic antibody production does not occur to any appreciable extent against sheep red cell antigens, but it is possible that the soluble polysaccharide antigens might disseminate more freely in the body and stimulate antibody production more efficiently in other organs.

Several experiments were performed to test this possibility. Mice were immunized with isologous red cells coated with the polysaccharide antigens, and their spleens, lymph nodes and thymus glands were removed at various intervals and tested for the number of PFC. In addition, lymphoid cells from the peripheral blood were isolated by mixing equal volumes of blood (in isotonic citrate solution) with 3 per cent 'dextran 250' (Pharmacia, Sweden) for 1 h at room temperature. The supernatant, which contained mainly white cells, was washed and used in the agar-plaque technique.

It was constantly found that PFC occurred in extra-splenic lymphatic organs, mostly in the lymph nodes and the peripheral blood but also in the thymus. The number of PFC per million cells in the thymus varied greatly between different animals, but occasionally reached higher values than in the lymph nodes and the peripheral blood. The kinetics of antibody production in these organs, however, paralleled that in the spleen. Thus, the maximum number was found about the same time in all organs (day four as a rule) and thereafter declined rapidly. Usually, significant numbers of PFC were only found at days 4–5 in the thymus, lymph nodes and peripheral blood. Although the number of PFC per 10<sup>6</sup> lymphatic cells was sometimes high in the extra-splenic organs, their absolute amount was insignificant compared to that in the spleen. Since no shift of the antibody-producing cells occurred from the spleen to other lymphatic organs after the peak at days 3–5, it is unlikely that the difference between

detectable cellular antibody synthesis and serum antibody titres is caused by extra-splenic production.

The foregoing results demonstrate that 19S antibody production against soluble lipopolysaccharide antigens can be detected at the cellular level. The kinetics of the cellular antibody production is similar to that against sheep red cells: a maximum number of PFC is reached after 3-5 days and then rapidly decreases. The humoral antibody response is only of the 19S-type, even after hyperimmunization with antigen incorporated into Freund's complete adjuvant. It develops in parallel with the PFC during the first four days, but then continues to increase and reaches a steady state for 3-5 days before declining, whereas the PFC rapidly disappears after the fourth day. This discrepancy between detectable cellular production of only one type of antibody (19S) and serum antibody titres cannot be ascribed to cumulation of serum antibodies or to extra-splenic antibody synthesis. It is noteworthy, however, that antibody synthesis was observed in the thymus and the peripheral blood. Occasionally the thymus contained a larger fraction of antibody-producing cells than the lymph nodes. A similar observation has also been made by M. Landy (personal communication) in rabbits immunized against polysaccharide antigens. At this stage it is only possible to speculate about the mechanism responsible for the difference in detectable cellular synthesis of antibodies and their presence in the serum. It seems possible that it is caused by changes in some properties of the 19S

antibodies produced, analogous to the shift from 19S to 7S antibodies occurring with other antigens. According to this hypothesis, highly efficient haemolytic 19S antibodies are produced by lymphatic cells during the first 4 days after immunization, which are capable of producing plaques *in vitro*. As a result of a maturation process a new type of antibodies is produced, which is still of the 19S-type, but has a lower haemolytic efficiency. These antibodies would not be detected in the agar-plaque technique, but easily in test-tube methods when mixed with the target cells. The late 19S antibodies would thus have properties similar to 7S antibodies in other immunological systems. Alternative explanations might exist, however, such as a delayed antibody production against new antigenic constituents of the polysaccharide antigen. Such antibodies might be incapable of producing plaques, but efficient in test-tubes.

## BIOSYNTHESIS OF L-ASCORBIC ACID IN DIFFERENT SUB-CELLULAR FRACTIONS OF PRENATAL AND POSTNATAL RAT LIVERS

By I. B. CHATTERJEE,\* ZANE H. PRICE and PROF RALPH W. MCKEE

Departments of Biological Chemistry and Medical Microbiology and Immunology, School of Medicine, University of California, Los Angeles

USE of the Hogeboom method<sup>1</sup> for differential centrifugation and isolation of different sub-cellular components from adult rat liver homogenate revealed that D-glucurono reductase and L-gulonolactone, the enzyme systems converting D-glucurono lactone and

L-gulonolactone into L-ascorbic acid, are located almost entirely in the particulate fraction sedimented between 8,500g and 88,700g (refs. 2, 3). This fraction is usually called the microsomal fraction.

Employing the same technique of differential centrifugation<sup>1</sup>, experiments with Sprague-Dawley rats indicate that L-gulonolactone and L-gulonolactone dehydrogenase are

Condition of rat	Age	Synthesis* of L-ascorbic acid, $\mu\text{g}/\text{mg}$ protein					
		Protein content, mg per g liver		200g fraction		8,000-70,000g fraction	
		200-8,000g fraction	8,000-70,000g fraction	In air	In absence of air	In air	In absence of air
Prenatal†	18 days	10	4	2	6	20	Nil
"	20 days	12	6	2	8	25	Nil
"	21 day (term)	14	8	3	9	—	7
New-born ♀	24 h	20	16	5	9	—	21
Young ♀	15 days	25	20	10	10	—	88

\* Systems and methods employed: total volume of incubation mixture was 2.5 ml. containing 0.25–1.0 g liver equivalent of microsomes, 0.02 M sodium phosphate buffer, pH 7.2, 4 mg of L-gulonolactone, 0.005 M sodium pyrophosphate and 0.001 M KCl; incubated for 1 h at 37° in air. In anaerobic incubation sodium pyrophosphate was omitted, the L-gulonolactone and 2 mg phenazine methosulphate were placed in the side arm of a Thimbley tube. L-Ascorbic acid was estimated by titration with 2,6-dichlorophenol indophenol and the protein was estimated by biuret method after precipitating the protein with trichloroacetic acid†.

† No attempt was made to determine the sex of the foetuses.

entirely absent from the so-called microsomal fraction of liver homogenate obtained from embryonic rats up to 20 days of gestation (Table 1). However, the foetal liver homogenate was found to contain a small amount of activity for the synthesis of ascorbic acid. This activity is located in the fractions sedimented at 200g and between 200g and 8,000g (Table 1). The activity of these fractions did not increase significantly after birth (Fig. 1). On the other hand, the activity of the fraction sedimented between 8,000g and 70,000g which is absent from foetal liver, starts on the 21st day of gestation (term), increases after birth, attaining a maximum on the 14th–15th day, and then falls to values of 50–60  $\mu\text{g}$  ascorbic acid per mg protein (Fig. 1). The further decrease in biosynthetic capacity of liver microsomes from female rats at an age of 35–45 days (Fig. 1), the age of attaining sexual maturity,

Abscissa: days before and after the 21-day term period for the rat. Ordinate:  $\mu\text{g}$  L-ascorbic per mg protein.

Fig. 2. Thin section of 18-day foetal rat liver fraction sedimented at 200–8,000g. The tissue was ground with a Ten Broeck glass tissue homogenizer employing 0.25 M sucrose. The pellet was fixed with osmic acid and embedded in 'Epon'. Note the unusually large vesicles with attached ribosomes. Fraction contains some mitochondria. ( $\times 55,000$ )

Fig. 3. Thin section of 14-day-old rat liver fraction sedimented at 200–8,000g. The tissue was treated as in Fig. 2. Mitochondria is the essential component with slight microsomal (arrows) contamination. ( $\times 60,000$ )

is not observed with the microsomes from male rats. Similar results are obtained when the enzymatic activity is expressed per g of liver instead of per mg microsomal protein.

It would appear from Table 1 and Fig. 1 that, in the foetal liver homogenate, the ascorbic acid synthesizing enzymes are located in the so-called nuclear and mitochondrial fractions. However, when the so-called mitochondrial fraction from foetal rat liver homogenate, sedimented between 200g and 8,000g, was examined with the electron microscope, the fraction was found to be composed of 90–95 per cent microsomes, the rest being mitochondria and other cell organelles (Fig. 2). On the other hand, the same 200–8,000g particulate fraction from a 14-day-old or an adult rat liver homogenate was found to be composed of almost pure mitochondria with slight microsomal contamination (Fig. 3). In the foetal liver homogenate, the fraction sedimented between 8,000g and 70,000g has been tentatively identified on the basis of morphology as free ribosomes and some smooth vesicles (Fig. 4). The comparable fraction from a 14-day-old or an adult rat liver homogenate contained a larger proportion of smooth vesicles (Fig. 5).

Fig. 4 Thin section of foetal rat liver fraction sedimented at 8,000-70,000g. The tissue was treated as in Fig. 2. The major portion of the fraction consists of what have been tentatively identified as free ribosomes with some relatively large smooth vesicles intermixed. ( $\times 70,000$ )

Fig. 5 Thin section of 14-day-old rat liver sedimented at 8,000-70,000g. The tissue was treated as in Fig. 2. The distribution of free ribosomes and vesicles is about equal. A few fragments of smooth tubular endoplasmic reticulum can be observed. ( $\times 55,000$ )

The results indicate that the liver microsomes from embryonic rat are apparently different from those of young or adult rats being sedimented at a much lower centrifugal force and having much less enzymatic activity

for synthesizing L-ascorbic acid. As appears from the electronmicrographs (Figs. 2 and 5), the microsomal vesicles, as well as the ribosomal granules from embryonic liver, sedimented under the same conditions are strikingly larger than those from an adult liver. The larger vesicle size and the ribosomes being attached would perhaps explain why the embryonic microsomes sedimented at a much lower centrifugal force. However, differences in chemical composition of the particulates, as well as differences in the physical properties, may also account for sedimentation at a lower centrifugal force. Further work is needed to explore this and to determine how and when the transition of the foetal liver microsomes to adult liver microsomes occurs. Whether similar transition also occurs in microsomes from other organs has yet to be learnt. The few mitochondria present in the embryonic rat liver proliferate rapidly after birth. The phenomena of mitochondrial proliferation and the transition of foetal microsomes to adult microsomes may not be merely coincidental and may merit further investigation.

It should be mentioned that Peters *et al.*<sup>4</sup> observed a morphological ergastoplasmic differentiation between prenatal and neonatal mouse liver. A smooth tubular form of endoplasmic reticulum was found to appear at birth which was completely absent from a foetal liver of 18 days gestation. In confirmation of their finding, Fig. 2 shows that the microsomes from foetal rat liver are all of rough or granular type and none of them is smooth or agranular. On the other hand, the microsomes from an adult rat liver are known to be composed of both rough and smooth types of vesicles (ref. 5 and Fig. 5). However, it is not known at present whether the ascorbic acid synthesizing enzymes are associated especially with the smooth types of endoplasmic reticulum which are absent from the foetal liver.

Under the electron microscope, the nuclear fractions from both prenatal and postnatal, and the mitochondrial fraction from postnatal, liver homogenates were found to contain some microsomes (Fig. 3). Hence, in confirmation of the previous findings<sup>1</sup> it may be stated that the enzymatic activities of these two fractions are due to contamination by microsomes. The low biosynthetic capacity of the embryonic microsomes is not due to the presence of some inhibitor, since addition of embryonic microsomes to adult microsomes did not inhibit synthesis by the latter.

## CHROMOSOME DAMAGE IN HUMAN DIPLOID CELLS FOLLOWING ACTIVATION OF LYSOSOMAL ENZYMES

By DR. A. C. ALLISON and Miss G. R. PATON

National Institute for Medical Research, Mill Hill, N.W.7, and Hampstead, London, N.W.3

CHROMOSOME or chromatid aberrations are known to follow exposure of cells to X-radiation, ultra-violet radiation, virus infections and a variety of chemical compounds differing widely in structure<sup>1</sup>. It has been generally accepted that such aberrations are due to direct physical or chemical attack on chromosomal material,

probably DNA. However, several observations have led us to investigate another possibility, that scission of chromatids could be produced by enzyme action and might therefore result from activation of hydrolytic enzymes in the living cell. In particular, it seemed possible that deoxyribonuclease (DNase) or other enzymes

liberated from the cytoplasmic organelles known as lysosomes might be able to enter the nucleus and produce structural alterations in chromosomes.

To test this hypothesis a method of selective activation of lysosomal enzymes developed in our laboratory<sup>3</sup> has been used. The method depends on the fact that living cells take up certain dyes or other compounds and concentrate them in lysosomes. When the cells are exposed to light of wave-length absorbed by the chromophore, photo-oxidative changes in the membranes of the lysosomes are produced. Light of these relatively long wave-lengths is not injurious to cells except where the photosensitizing agent is present. Hence damage to lysosomes, with release of the enzymes they contain, can be achieved without direct damage to the nucleus or other cytoplasmic constituents. This method of activating lysosomal enzymes is much more specific than the use of detergents, enzymes or antibodies. If the concentration of dye or time of illumination is sufficient, the cells are killed<sup>3</sup>, but lower doses produce other interesting effects including the chromosome aberrations now reported.

**Cell cultures.** The human diploid cell strain, WI-38, isolated by Hayflick from human embryonic lung, was obtained from Mr. J. P. Jacobs. Medium for cell growth consisted of Eagle's basal medium (in Hanks's balanced salt solution) containing 8 per cent calf serum and 0.05 per cent bicarbonate, with 200 units penicillin and 100 µg streptomycin per ml. The cells were dispersed and propagated in 4-oz. bottles using the methods described by Hayflick and Moorhead<sup>4</sup>. Repeated tests of the cell strain for bacterial or mycoplasma contamination were negative, and routine examination of the chromosomes of these cells in our laboratory have revealed no abnormalities.

**Photosensitizing agents.** Neutral red, vital and fluorochrome, was obtained from G. T. Gurr, London. Acridine orange was purchased from E. Gurr, London. These samples contained several components and purification was carried out by silica-gel chromatography using three solvent systems, namely, butanol: ammonia, butanol: acetic acid and pyridine, isoamyl alcohol: ammonia. Samples of anthracene and acridine highly purified by zone-melting were obtained from the National Chemical Laboratory.

**Photosensitizing technique.** Twenty-four h after sub-culturing the cells, photosensitizing agents were added to the medium in concentrations varying from 1 in  $10^4$  to 1 in  $2 \times 10^5$  (w/v). The dyes were soluble in the medium, but anthracene and acridine were dissolved in serum as previously described<sup>4</sup> and added to the medium. The cells were incubated at 37°C for 1 h, after which the medium was replaced with fresh medium without the photosensitizing agent and the cells were incubated for a further 0.5 h. This was done to avoid immediately lethal damage to cell membranes which occurs if the photosensitizing agent is present in the medium at the time of illumination. Cells were illuminated with a high-intensity tungsten or low-pressure mercury discharge source with appropriate filters. Cultures were 5 in. from the tungsten source (Philips 'No. 2 Photolite'); this system with a 'Cinemoid 21' filter (Strand Electric Co.) was used for neutral red and No. 17 filter for acridine orange. With acridine and anthracene the mercury vapour source (4 Philips 'TL AD'05 tubes) was used with glass and No. 25 filters 4 in. from the culture. Cells were illuminated for 0.5 or 1 h at room temperature, with heat-absorbing filters and fans to prevent significant rise in temperature. Controls were kept at room temperature for the same time or were illuminated without any photosensitizing agent. All cultures were then incubated at room temperature for a further 24 h before chromosomes were examined.

**Chromosome preparations.** These were made by a modification of the technique of Moorhead and Nowell<sup>5</sup>. Cultures were usually treated for 3 h with 'Colcemid'; some comparisons of break frequencies with and without 'Colcemid' showed no significant differences. The cells were fixed in

Fig. 1. WI-38 cells exposed to neutral red (1 in 30,000) for 1 h, showing uptake of dye in lysosomes (L). Nuclei (N) are unstained. ( $\times c. 740$ )

acetic alcohol, spread on slides over a low flame, hydrolysed and stained with Giemsa. The slides were coded and counted blind. In each preparation under the low power of the microscope 50 or more well-spread metaphases were chosen for detailed examination at high magnification. Broken cells with scattered chromosomes were rejected. A cell with one or more definite breaks was recorded as positive. Obscured or indefinite breaks, secondary constrictions or unstained gaps were recorded as negative. The final result shows the number of cells with one or more breaks as a percentage of the total number of cells examined. Chromatid and chromosome breaks were not differentiated; the latter were occasionally observed, but much less frequently than chromatid breaks. Occasional cells showed chromatid exchanges and 'triradial' configurations (Fig. 3).

The intracellular distribution of the photosensitizing agents was examined by direct or fluorescence microscopy. As previously described<sup>6</sup> neutral red (Fig. 1), anthracene and other polybenzenoid hydrocarbons and acridine are seen only in lysosomes, whereas acridine orange fluoresces in both the nucleus and lysosomes. Even at concentrations of neutral red, anthracene or acridine a hundred times higher than those used for photosensitization no nuclear uptake is seen unless the cells are damaged. It therefore seems certain that the primary photosensitizing effects of these substances are on lysosomes. Acridine orange was used for comparison with similar experiments previously published on plants<sup>7,8</sup>, which will be discussed here. In this case direct photosensitization damage to the nucleus is possible.

The results of two representative experiments are summarized in Table 1. The number of breaks is clearly higher in cells photosensitized with any of the agents used. The results in Table 1 show that the photosensitizing agent does not produce breaks in the absence of light, and previous observations<sup>9,10</sup> have shown that oxygen must be present for killing cells and for structural alterations in chromosomes to occur.

Three other experiments gave similar results, with statistically significant differences between treated and control cells, although somewhat higher percentages of breaks were found in two sets of controls in which the cells used were at a later passage level, 32 or 33.

Although the experiments were undertaken for different reasons, our results confirm for animal cells the observations previously made by Kihlman<sup>11</sup>, and Dubinin *et al.*<sup>12</sup> in plants. These authors found that by treating broad bean or onion root-tips with low concentrations of acridine orange, rivanol, methylene blue or toluidine blue, and illuminating them with visible light, structural chromo-

\* Numerous breaks seen in some cells.

† Three triradial configurations present.

some changes could be produced. It was concluded that these treatments damaged nuclei directly, which is possible in the case of acridines but not with methylene blue or toluidine blue. We have observed that in both *Vicia* root-tip cells and mammalian cells methylene blue and toluidine blue are concentrated in cytoplasmic organelles which in the case of mammalian cells can be definitely identified as lysosomes, as Brachet some time ago suggested<sup>8</sup>. The same cytoplasmic organelles in plant cells fluoresce flame red after uptake of acridine orange at concentrations about 1 in  $10^4$  while nuclei fluoresce green, and the fluorescing cytoplasmic organelles may be equivalent to those in plants showing particulate staining for acid phosphatase<sup>10</sup>. From these observations it seems likely that plant cells also have lysosomes, so that our interpretation of chromatid breakage could apply to plant as well as to mammalian cells.

The experimental results suggest that a cytoplasmic event, namely damage to lysosomes, can lead to structural alterations in chromosomes.

The most likely interpretation seems to be that DNase released from lysosomes can break the DNA which is the backbone of the uncoiled interphase chromatid. This enzyme very efficiently fragments lampbrush chromosomes<sup>11</sup> and chromatin from sea-urchin sperm<sup>12</sup>, and produces visible changes in parts of the polytene chromosomes in living *Drosophila* cells<sup>13</sup>. Other enzymes, includ-

Fig. 3. Chromosomes from a culture of WI-38 cells at passage 33 treated with neutral red (1 in  $10^4$ ). Arrows indicate a chromatid break and a triradial configuration.  $\times 1,875$ Fig. 4. Chromosomes from a culture of WI-38 cells at passage 25, treated with acridine orange ( $2$  in  $10^5$ ). Arrows indicate chromatid breaks.  $\times 1,320$ Fig. 2. Chromosomes from a control culture of WI-38 cells at passage 27.  $\times 1,375$ 

ing proteases and RNase, do not break chromosomes. In fact, lysosomal DNase has a remarkable property: it appears from the reaction kinetics to break both strands of a double-helix of DNA at the same time<sup>14</sup>. Simultaneous scission of both strands produced in this way would be much more difficult to repair than breaks in one of the two strands, as is characteristically produced by a single hit with pancreatic DNase<sup>14</sup>. Hence one or a very small

number of scissions by lysosomal DNase might give rise to breaks later visible in the coiled mitotic chromatids.

There are two main difficulties about postulating that lysosomal DNase produces chromatid breaks. The first is that the enzyme would have to enter the nucleus. There is evidence that this could happen: thus DNA-dependent RNA polymerase activity in isolated nuclei is immediately stopped by addition of DNase<sup>18</sup>. Moreover, shortly after infection with herpes simplex virus there is often considerable breakdown of host cell DNA<sup>19</sup>, which is apparently due to activation of lysosomal DNase<sup>17</sup>. It therefore appears that nucleases can enter the nucleus and act on its contents. The second objection is that lysosomal DNase has an acidic pH optimum, but the enzyme has, in fact, appreciable nuclease and phosphodiesterase activity at neutral pH<sup>18</sup>. Experiments with purified lysosomal DNase and inhibitors are planned and these, it is hoped, will provide more direct evidence for or against the hypothesis that this enzyme is involved in the production of chromatid breaks.

Another possible objection to our experiments is that free radicals formed after photon absorption in the lysosomes might be able to diffuse to the nucleus and damage its contents directly. This seems highly improbable. The concentrations of the photosensitizing agents used were very low ( $<10^{-8}$  M) and those of free radicals generated would be lower still. It is known that in the presence of protein and other reactive materials the life-times of such free radicals are exceedingly short<sup>9,10</sup>. Calculations show that the quantum efficiency of chromosome breakage is approximately the same whether the photosensitizer is present in the lysosomes only or in the lysosomes and nucleus.

The results of cytogenetical investigations are consistent with the view that a number of chemicals, including the standard alkylating agents and maleic hydrazide, produce effects similar to those described in this article, perhaps by a similar mechanism. Discussing the results of experiments with maleic hydrazide, Evans and Scott<sup>20</sup> conclude that probably breakage of both old and new strands of DNA in a chromatid occurs during the period of DNA synthesis. At this time the DNA, being fully extended for replication, would be particularly vulnerable to enzymatic attack, and the lysosomal enzyme could break both old and new strands of the helix at the same time. Experiments with synchronized cells have been started to ascertain at what stage of the replication cycle chromosomes are most sensitive to photosensitization damage. We do not imply that the only way in which chromatids are broken is enzymatic attack: clearly direct interactions with DNA or interference with repair are also likely to occur. But enzyme activation could represent an important contributory mechanism in chromosome damage caused by chemicals and radiations, the significance of which has so far been overlooked.

These results have a bearing on the suggestion made previously<sup>4</sup> that lysosomal damage might play a part in carcinogenesis. This suggestion was based on the observation that carcinogenic hydrocarbons are concentrated in lysosomes and can induce permeability changes in their

membranes. Likewise, viruses, ultra-violet and X-radiation and various chemical carcinogens and co-carcinogens are able to bring about release of enzymes from lysosomes. The results of our experiments suggest that the lysosomal enzymes can react with and produce lasting changes in genetic material. Some such change—not necessarily chromosomal—might transform a normal cell into a malignant cell. Since so many diverse agents can produce cancer it seems likely that some common reaction in cells is involved, and lysosomal enzyme activation seems at least as plausible an explanation as alternatives that have been much discussed, namely, protein binding and deletion by carcinogenic chemicals<sup>21</sup> or direct binding carcinogenic chemicals to nucleic acid<sup>22</sup>. Apart from the fact that the lysosomal concept has more generality, evidence has already been presented that activation of lysosomal enzymes can release cells from mitotic inhibition<sup>23</sup>. This view will be elaborated with more detail and further experimental evidence elsewhere; but clearly if such release from mitotic inhibition could be made permanent by elimination of the control mechanism, genetic or otherwise, malignancy might well ensue.

Chromosome aberrations in mammalian cells have now been seen after infections with a number of viruses<sup>4</sup>. Most of these viruses multiply in the nucleus and might damage its constituents directly. However, some viruses giving rise to chromosomal aberrations, such as yellow fever virus<sup>24</sup>, have no known phase of development in the nucleus. Nevertheless they do damage lysosomes (as shown by plaque formation) and chromosome breaks might therefore be produced by the mechanism suggested in this article.

We thank Dr. P. J. Walker for a pure sample of acridine orange, Dr. H. J. Evans for his advice, Mrs. P. Bradbury for the statistical analyses, and Mr. J. Clark and Mr. F. Wanless for the photomicrographs.

## IRRIGATION OF PLANTS WITH ATMOSPHERIC WATER WITHIN THE DESERT

By DR. I. GINDEL

Volcani Institute of Agricultural Research, Rehovot, Israel

THE desert soils are suitable, so far as the climate and the quality of the soil are concerned, for the growth of many forest tree species which can occupy most of the area but the expansion of which is prevented

solely by the lack of water. This shortage has given us the idea of exploiting water from dew and mist of irrigation of forest plants, and of concentrating the little rainwater available into the immediate area of the roots.

There are many species of xerophytes which can be utilized for afforestation even in desert regions where only 100–200 mm of rain fall annually, if they are irrigated for the first 2 or 3 years after planting. This conclusion is based on the results of afforestation in the Negev Desert over the past 20 years, and now woods, avenues and windbreaks of tamarisk, eucalyptus and Aleppo pine lend a touch of green to the grey, arid desert vista.

By exploitation of water from dew and mist, which is actually greatest in the desert, and by concentration of the rainwater in the root region, as is described in this article, it is possible to-day to plant endemic and domesticated xerophytes woody species at every place where such sources of water are available.

**Experimental areas.** The desert vegetation of Israel is defined phytogeographically as Saharo-Sindian, and many Saharan species are represented, such as *Acacia* sp., *Tamarix* sp., *Retama* sp., etc.

The investigation recorded here was limited to the sub-tropical zone of Israel and to those desert regions possessing the following characteristics: (1) A total annual rainfall of 25–200 mm (Beer-sheva-Eilat), limited to the cooler season. (2) The rainfall is limited to 8–10 days in dry years and 20–40 days in normal years. During the rest of the year, the sky is clear and the number of hours of sunlight is close to a world maximum. (3) Extreme annual fluctuations in the rainfall and frequency of drought years. (4) Scarcity of streams and rivers, apart from a gravitational flow from the mountains into the depressions

fluctuations were not only influenced by thermodynamic factors, but also by soil structure and topography (hills). (3) More dew is attracted by plants grown in light soil than in clay soil. (4) That measured in plantations was about half that in nearby exposed areas.

**Experimental Methods.** The water from the dew and mist was collected in exposed areas.

In order to ascertain the quantity of dew and mist falling nightly in different parts of the country and during different seasons, the apparatus illustrated in Fig. 1 was assembled. It was based on a calculation of the amount of water from dew and mist as a function of area. The apparatus was fitted up in the form of an inverted V with the ratio of height to width = 0.5 : 1.0. Each face was 2.5 m<sup>2</sup> in area and was covered with a sheet of polyethylene, 0.1 mm thick. Beside the shorter posts, at the edge of the gutter, were 2 polyethylene bottles into which the water was led through a pipe from a gutter. This 'roof' was supported on two pairs of posts of differing height, in the range of 40–60 cm, so as to form a slope which would lead the water into the bottles from the gutters. Polyethylene was chosen as an inactive water collector as it is non-hygroscopic and becomes cool at night. The flow into the bottles began when the sheet was sufficiently moistened, this preventing loss by evaporation. Apart from this means of measuring the water collected on the upper surface of the sheet, reversal of the 'roof' enabled the measurement of that forming on the underside, thus giving an overall estimate of the dew.

Fig. 1. Measurement of the water from dew and mist as a function of area. The apparatus is covered with polyethylene

and plains. This flow ceases after a few days as the water reaches the Dead Sea and the Red Sea. (5) An almost complete absence of sweet water suitable for drinking or for the use of plants.

Although there are local variations, there is a general distribution in the number of dewy nights<sup>1</sup> as follows: (1) An increase in the number of nights with dew and its quantity going southwards in the country; an annual variation between 5 mm—Dead Sea region and 150 mm—north Western Desert. (2) There are, in fact, the greater number of dewy nights during the hottest and driest months. (3) In the Western Desert, where the rainfall is lowest, the number of nights with dew reaches 250 annually (Gvuloth), 140 of these with 'heavy' dew. (4) Along the Mediterranean coast, in the Central Hula Valley and in the west-central part of the Valley of Israel the dew is heavy. (5) There are about 160 nights with dew in the hills with fluctuations depending on height and exposure; there is least on the eastern slopes.

Gilead and Rosenan<sup>2</sup> measured the number of nights with dew and the quantity collected at 80 meteorological stations in the country at the same time, over a period of 10 years, by means of Duvdevani's apparatus<sup>3</sup>, and reached the following conclusions: (1) The number of nights with dew is more or less constant, and the fluctuations are similar to those found in the rainfall. (2) There was no constancy between the various stations, and the

For irrigation of plants, polyethylene sheets, 1.5–2.0 m<sup>2</sup> in area, were arranged at a slope of 25–30 per cent (Fig. 2) to facilitate flowing of the water and its transportation to the plant-pit. Plastic ducts were attached to the lower ends of the sheets. To create the necessary slope the soil was ridged or, alternatively, the sheets were placed on wooden board.

**Amount of 'Flowing' Dew and Mist per Unit Area.** Some nights were completely dewless; on others, although drops condensed on the sheet, the amount was insufficient to lead to a flow through the gutters into the bottles. The flow of water from dew and mist into the measuring bottles of the apparatus begins when the sheet has become appreciably covered with drops. Table 1 indicates the 'flowing' water collected per square metre of polyethylene. This flow differed in 3 places belonging to different climatic regions (Revivim—desert, Eshtaol—sub-tropical hills, and Rehovot—semi-arid plain), with most at Revivim and least at Rehovot.

The apparatus was arranged with its two planes facing north and south, respectively, and here, also, differences emerged. Table 2 shows the greater flow from the north face at Revivim and Rehovot, and from south face at Eshtaol. In the summer of 1964, however, the southern aspect gave a greater flow at Rehovot.

**Irrigation of Forest Saplings with Atmospheric Water.** In 1962, 8–10-month-old saplings of the following species

were planted at Rehovot and in the Judean Hills (Hulda): *Pinus halepensis*, *P. brutia*, *Cupressus horizontalis*, *Eucalyptus gomphocephala*. *Tamarix aphylla* seedlings were planted in dunes south of Beersheba. Near each plant was arranged a plastic sheet, 1.3 m<sup>2</sup> in area as described previously. The dew was led to the plant-pit through a plastic gutter.

The experiments were repeated in the summer of 1963 and, apart from those saplings planted in the rainy season, others, of the same species, were also planted in August, when the conditions (heat and drought) are unsatisfactory for survival. One group was provided with atmospheric water by means of the plastic sheets, while the other was planted nearby without such aid. While the former survived until the winter rains, the latter had dried up by the beginning of September.

**Concentration of Rainwater by Means of Plastic Sheets.** The same plastic sheets which had proved useful for the collection of dew and mist were also used for the collection of rainwater. Table 3 shows the slight and unreliable rainfall in the desert over the past 10 years with fluctuations from 82 to 177 mm at Revivim, and from 100 to 255 mm at Gvuloth. These figures also include a number of light showers, of 0.5–1 mm, which only wet the upper 1–2 cm of the soil. This moisture evaporates within a few days, owing to the strong sunshine between the showers even during the rainy season. By concentrating this rainfall, its effectiveness can be increased. For example, a sheet of 5 m<sup>2</sup> area supplying a pit of 1 m<sup>2</sup> area may provide 5 times as much water as when water falls on a similar pit which is not provided with a sheet and, consequently, a 5-fold percolation. In fact, the percolation depends on the physical properties of the soil, especially its permeability, which is greatest in dunes, and least in loess.

**Discussion.** The collection of atmospheric water and the trapping of rainwater, by means of hygroscopic material (polyethylene or polyvinyl chloride), increase the sylvicultural potentialities of desert and semi-arid regions.

It was found that 20–30 l. of atmospheric water flowing into the plant-pit from each square metre of the polyethylene roof was sufficient for the continued existence and for some growth of the tree xerophytes used in this work, during the first summer after planting. It is possible, also, to plant woody xerophytes, such as Aleppo pine, *Tamarix* sp., and *Eucalyptus* sp. and others, even in midsummer (July–August) when the amount of dew

Table 3 YEARLY RAINFALL (MM) AND NUMBER OF RAINY DAYS AT TWO LOCATIONS

Year	Location	
	Revivim	Gvulot
1953/54	113.2 (27)	—
1954/55	92.0 (19)	148.8 (19)

1956/57	177.5 (34)	224.5 (43)
1957/58	32.4 (22)	100.3 (25)
1958/59	120.5 (32)	142.3 (22)
1959/60	44.1 (16)	—
1960/61	104.4 (32)	111.5 (8)
1961/62	71.8 (26)	162.1 (24)
1962/63	32.8 (8)	48.9 (20)
1963/64	164.9 (33)	248.7 (38)

reaches maximum, and they can be maintained without wilting so long as they are provided with moisture from dew and mist until the advent of the rains. In such places as the deserts of Chile and Peru, for example, this is even more important, since the mists may reach an annual value of 300–400 mm, while the actual rainfall does not exceed 40 mm.

October	51.58	48.42	47.9	52.1	50.9	49.1
November	61.18	38.82	49.1	50.9	61.5	38.5
December	60.64	39.36	—	—	50.52	49.48

The arbori-sylviculture possibilities in the desert may also be increased by the concentration of the little rainwater available in the region of the root. Here, also, the efficiency depends on the area of the sheet, and it can be adapted to the species. If, for example, a certain region would allow the growth of any forest tree species so far as the soil and climate are concerned, but the annual rainfall is only 200 mm instead of the 1,000 mm necessary, it is possible to increase the rainwater available by leading the run-off from a 5 m<sup>2</sup> sheet into a plant-pit of 1 m<sup>2</sup> area.

The xerophytes which are being used to-day in afforestation in Israel can be planted in any place where there is sufficient dew and mist to cause a flow into the plant-pit; this method overcomes the need for transportation of water by tankers or the installation of irrigation systems. This collection of rainwater also serves to wash out the salts which have become concentrated in the upper soil layer, especially due to the low chlorine content of atmospheric water.

# REGULATION OF PROTEIN AND NUCLEIC ACID SYNTHESIS BY GIBBERELLIN DURING LEAF SENESCENCE

By R. A. FLETCHER\*

Department of Agriculture

AND

Dr. DAPHNE J. OSBORNE

Agricultural Research Council Unit of Experimental Agronomy, Department of Agriculture, University of Oxford

**D**URING senescence in leaves, yellowing and loss of chlorophyll occur together with a progressive decline in the rates of synthesis of protein and nucleic acid. These changes can be retarded by the addition of certain plant growth regulators. Thus when excised leaf disks of *Xanthium* or *Nicotiana*<sup>1,2</sup> are supplied with a synthetic kinin or when those of *Prunus*<sup>3</sup> are treated with an auxin the incorporation of radioactive precursors into protein and RNA is maintained or even enhanced and senescence of the disks is retarded, although no other additional substrates are supplied. These observations have led to the proposal<sup>4</sup> that senescence in leaf cells is associated with the hormonal regulation of protein and nucleic acid synthesis and that both auxins and kinins retard senescence by maintaining the DNA as a functional template for DNA-dependent synthesis of RNA.

The hormonal content of leaves declines as they grow older. Where retardation of senescence can be brought about by the addition of synthetic auxin or kinetin it seems most probable that senescence is causally related to a limiting concentration of an endogenous auxin or kinin.

Evidently the hormone needed to retard senescence is not the same for all species, for an auxin will not retard leaf senescence in *Xanthium*<sup>5</sup> and kinetin is ineffective when supplied to *Prunus*<sup>3</sup>. So far, however, there is little information concerning the regulation of biochemical processes of senescence by another major group of endogenous hormones, the gibberellins.

Although it has been observed that gibberellin (GA) delays autumnal yellowing in some deciduous trees<sup>6</sup> and to some extent increases longevity of leaves of sugar beet<sup>7</sup>, no analyses of the physiological or biochemical effects have been made.

These aspects have now been studied in a wide range of species and it is clear that senescence can be effectively retarded in leaves of *Taraxacum officinale* by either gibberellin A3 or by kinetin. The effects of GA appear to be species specific, for in 17 other plants studied, no retardation of leaf senescence was observed. Some of the experiments on GA regulation of senescence processes in *Taraxacum* are now reported.

Mature leaves were gathered from wild plants, and disks punched from interveinal portions of the blades. Matched disks were placed in Petri dishes on filter paper moistened with equal volumes of either water, or an aqueous solution of GA. The dishes were maintained at high humidity and incubated in darkness at 25° C. After four days the chlorophyll was extracted with hot 80 per cent ethanol and the optical density of the solutions measured at 665 mμ, the absorption peak of chlorophyll *a*. The values for the optical densities of the chlorophyll extracts from disks treated in various concentrations of GA are plotted in Fig. 1. The chlorophyll content of the control disks drops to less than half during the experimental period whereas in the disks treated with GA most of the chlorophyll is retained. GA concentrations

from 10 to 50 mg/l. appear to be optimal and 25 mg/l. has regularly been used in the biochemical studies.

With other species the addition of auxins or kinins<sup>1-4</sup> during senescence not only delays the loss of green colour in the leaves but also retards the fall in levels of total protein and RNA. The following experiment, based on the method described, was designed to ascertain whether GA maintains the protein and RNA levels in *Taraxacum*. Duplicate sets of disks cut at the start of the experiment, and disks that had been treated with water or GA for 4 days, were macerated and extracted, first in 80 per cent ethanol, then with 5 per cent TCA at 0° C, and finally with absolute ethanol and ethanol:ether (3:1 v/v). For protein determinations, the residue was subjected to N NaOH at 100° for 4.5 min to solubilize the protein, and an aliquot of the solution assayed by the biuret method. RNA was estimated in separate sets of disks. The residue remaining from the final extraction with ethanol:ether was hydrolysed with 0.3 N KOH for 18 h, the DNA precipitated by acidification to pH 2.0 with HClO<sub>4</sub>, and the RNA determined in the supernatant fraction by the orcinol reaction.

It is seen from Table 1 that after 4 days the contents of chlorophyll, protein and RNA in the disks that received only water have fallen considerably below the original level, while in those treated with GA this fall has been arrested, though not wholly prevented.

Table 1. CHLOROPHYLL, PROTEIN AND RIBONUCLEIC ACID CONTENT IN LEAF DISKS OF *Taraxacum officinale*, AFTER TREATMENT WITH 25 MG/L. GIBBERELLIN (GA) OR WATER

Sample	Treatment	Chlorophyll optical density at 665 mμ	Protein (mg)	RNA (μg)
0 day	—	98	4.22	440
4 day	GA	73	3.06	353
4 day	H <sub>2</sub> O	43	2.11	304
S.E.		3.2	0.12	19.6

To establish whether GA retards the fall in protein level, by preventing the breakdown of already existing protein, or by maintaining its synthesis, the incorporation of <sup>14</sup>C-leucine into protein was determined after disks had been pretreated with either water or GA for 1 day.

Fig. 1. Retardation of chlorophyll degradation in leaf disks of *Taraxacum officinale* by gibberellin (GA). Chlorophyll content expressed as optical densities (O.D.) of 80 per cent ethanol extracts at 0 and 4 days

\* Present address: Department of Botany, University of Guelph, Guelph, Ontario, Canada.

A smaller disk was then excised from each original disk, so that all the disks presented freshly cut edges, and they were then floated on 1 ml. of aqueous medium containing 1.5  $\mu$ c. of  $^{14}$ C-leucine and 40,000 units of penicillin. After 3 h the disks were quickly rinsed and the protein extracted.

An aliquot of the protein solution was transferred to a planchet and the radioactivity was determined. These values were compared with those for the incorporation of  $^{14}$ C-leucine by comparable sets of leaf disks cut directly from the same leaves.

It is evident (Table 2) that after one day both the incorporation of  $^{14}$ C-leucine into protein and the specific activity of the protein in the disks supplied only with water is less than the initial values, indicating a lower rate of protein synthesis after one day. In the disks receiving GA, however, the synthesis of protein after one day is not only maintained but also enhanced, and the specific activity is higher than that on the initial day.

It is clear from another experiment (Table 3) that the synthesis of RNA is also stimulated by the addition of GA. The incorporation of  $^{14}$ C-adenine into RNA and the specific activity of the RNA are both significantly enhanced by pretreatment with GA for only 1.5 h. If actinomycin D is included in the medium before and during treatment with GA, the total incorporation of the  $^{14}$ C-adenine added later is reduced and the stimulation due to GA is abolished. Other experiments have

Table 2. INCORPORATION OF  $^{14}$ C-LEUCINE INTO PROTEIN IN LEAF DISKS FROM *Taraxacum officinale* FOLLOWING TREATMENT WITH GIBBERELLIN (GA)

Sample	Treatment	Protein mg	Total counts/min	Protein specific activity
0 day	—	4.81	13,075	3,025
1 day	H <sub>2</sub> O	4.06	10,275	2,525
	GA	4.56	14,650	3,200
S.E.		0.13		60.4

Disks pretreated with either gibberellin (25 mg/l.) or water for 1 day and incubated with  $^{14}$ C-leucine (U) (10.7 mc./mM) for 3 h.

Table 3. EFFECT OF GIBBERELLIN (GA) ON THE INCORPORATION OF  $^{14}$ C-ADENINE INTO RNA IN THE PRESENCE OR ABSENCE OF ACTINOMYCIN D (AM) IN LEAF DISKS OF *Taraxacum officinale*

Treatment	RNA $\mu$ g	Total counts/min	RNA specific activity
Am + GA	451	1,576	3.48
Am + H <sub>2</sub> O	440	1,512	3.44
GA	446	2,800	6.28
H <sub>2</sub> O	446	2,240	5.01
S.E.	21.4		0.15

Disks were pretreated in either H<sub>2</sub>O or Am (50  $\mu$ g/ml.) for 1.5 h at 25°. GA (to give 31 mg/l.) or H<sub>2</sub>O was then added to one set of disks from each pretreatment and incubation continued for 1.5 h. Adenine-8- $^{14}$ C sulphate (31.3 mc./m.mole) was then added to each treatment (to give final concentrations of  $^{14}$ C-adenine 2  $\mu$ c./ml., GA 25 mg/l. and Am 40  $\mu$ g/ml.) and incubation continued for 3 h.

shown that when this concentration of actinomycin D is added after the treatment with GA, the GA stimulation of RNA synthesis is fully maintained.

These findings indicate that the retardation of leaf senescence by gibberellin in *Taraxacum* is like that of auxin<sup>4</sup> and kinetin<sup>5</sup> retardation in other species, closely linked to a regulation of protein and RNA synthesis. These findings also support the contention that hormonal retardation of leaf senescence is associated with the maintenance of the DNA as a functional template for DNA-dependent synthesis of RNA. A fuller account will be published elsewhere.

We thank Prof. G. E. Blackman for his advice. This work was carried out during the tenure by one of us (R. A. F.) of a N.A.T.O. Science Fellowship awarded by the National Research Council of Canada. We thank Merck, Sharp and Dohme for the supply of actinomycin D.

## PLANT GROWTH RESPONSE IN AN ELECTROKINETIC FIELD

By L. E. MURR

Department of Engineering Mechanics, Materials Science Laboratory,  
Pennsylvania State University, University Park, Pennsylvania

IT has been shown previously that plants grown in an electrostatic field of sufficient magnitude have reduced ability to grow, as compared with corresponding control plants which did not experience such potential gradients<sup>1</sup>. In the investigation to be reported here, similar, but more severe, plant-leaf damage has been observed in yellow bush beans grown in a continuous 60-c/s alternating electric field. The extent of plant and leaf damage has been observed to be directly related to the magnitude of the electric potential gradient.

These experiments were conducted in a specially designed environmental chamber. The chamber was constructed of glass-panelled aluminium, air vented, and lit artificially with a bank of 100-watt incandescent lamps arranged to produce near daylight intensities at the soil surface in the experimental plot. Day length in all experiments was extended to 12 h, and soil moisture was rigidly maintained at  $12 \pm 1$  per cent by weight. A sand-humus-soil composite was used as the soil base. Chamber temperature and soil temperature were closely checked throughout all experiments to ensure identical thermal variations for all experimental data obtained. High-voltage power was continuously supplied during the entire 11-day period by a high-voltage a.c. testing transformer. The high-voltage experimental plot, which was placed in the chamber, was constructed entirely of polystyrene and epoxy-coated wood. The anode or upper electrode was made of an aluminium screen mesh; and

the cathode or soil base-plate was solid sheet aluminium which covered the base of the 300-in.<sup>2</sup> plot. This design was identical to that used in my previous work<sup>2</sup>.

Yellow bush beans were planted as seed directly into the field plot. The duration of each experimental run, determined by preliminary investigation, was established as 11 days. This period allowed the seeds to germinate, and the plants to attain heights just below the anode height of 12 in. above the soil surface. At least 25 seeds were planted, at 1-in. spacing, in each experimental run. The germination in these experiments is shown in Table 1, where electric field strength is represented as relative potential gradient in the manner established in previous investigations<sup>3</sup>. It should be apparent from Table 1 that germination is unaffected by an electrokinetic field as contrasted with supposed differences observed by Blackman *et al.*<sup>4</sup> for seeds germinated in a d.c. field.

Plant growth response, however, was very definitely affected by the electrokinetic field. Fig. 1 illustrates rather consistent plant growth retardation as a function of the relative potential gradient expressed in kV/m. The

Table 1. YELLOW BUSH BEAN GERMINATION IN AN ELECTROKINETIC FIELD

Control	90

\* Average of two replications.

growth retardation trend established in Fig. 1 is somewhat amplified by a dry weight analysis of plant leaves as shown graphically in Fig. 2. In Fig. 2, it is observed that leaf growth is significantly stimulated in the range 10–50 kV/m, while leaf yield on a dry weight basis decreases significantly at higher field gradient magnitudes.

Comparing the results of this research with previous results for grasses grown in an electrostatic field<sup>1</sup> suggests that the mechanism of destruction is similar, but plant damage is generally not a consistent phenomenon as illustrated in Fig. 2. It would seem, therefore, that the basic mechanism which initiates leaf damage in plants grown in an electrokinetic field is a type of field ionization action, as suggested earlier for grasses grown in an electrostatic field<sup>1</sup>. Such a field action is not associated with

Fig. 1. Plant growth-response curves for yellow bush beans grown in an electrokinetic field of various potential gradients. x, Control, □, 20 kV/m, ●, 40 kV/m, ○, 60 kV/m, ▲, 80 kV/m.

Fig. 2. Yellow bush bean leaf response based on an average of two dry weight comparisons of activated leaves at each electrokinetic potential gradient condition, and control leaves of an experimental run at the beginning and the end of the activated series.

Fig. 3. Photographs of typical yellow bush bean leaves, (a) activated plant leaf at an electrokinetic field gradient of 60 kV/m. Cell damage and tissue rupture are shown at the tip (A), and edge shrinkage caused by tissue dehydration due to the electrokinetic field action as shown at (B); (b) control leaf.

polarization of inorganic radicals in the plant biosystems, but rather a direct elastic rupture of epidermal cells by a type of molecular field fatigue. Such a process would be considerably amplified by an alternating field as compared with direct field action; and this has essentially been shown in the results presented in Fig. 1. However, it is apparent from Fig. 2 that the growth response based on leaf weight is affected by the potential gradient of the field.

Further proof of epidermal rupture by field action is presented in the photographs of Fig. 3. Leaf-tip and edge damage of a typical bush bean leaf exposed to a relative potential gradient of 50 kV/m is shown in Fig. 3 (a), and compared with an equally typical control (unexposed) leaf in Fig. 3 (b). Tissue disruption, elastic shrinkage, and leaf dehydration are unmistakable in (a).

These results provide evidence that the enzyme activity detected in plants grown in an electrostatic field<sup>1</sup> is associated with plant metabolic and respiratory acceleration, resulting from the direct epidermal destruction by the electric field action. Thus, following the initial exposure of leaf tissue and internal systems to electrokinetic field action, it is possible that more complete leaf damage results from the over-stimulation of respiratory enzymes, which are automatically concentrated in the leaf tissue by the metabolic recovery mechanisms. Similar cell damage by enzyme overstimulation has been observed for simple yeast cells by Schulke<sup>2</sup>.

The results presented in Fig. 2 can perhaps be interpreted in terms of such an enzyme stimulation. That is, for potential gradients of a moderate level (10–50 kV/m) leaf damage due to tissue rupture is not of a sufficient level to cause total leaf destruction. Respiratory stimulation is probably at a level where the plant is actually growing at a high rate. As the field strength is raised, the over-stimulation becomes 'toxic' to the leaf metabolism as suggested for grass plants grown in an electrostatic field<sup>1</sup>. This enzyme toxicity, combined with increased epidermal damage due to direct field evaporation of leaf tissue molecules, produces decreased yields, and eventual plant destruction. This phenomenon would seem to indicate that growth stimulation is possible in an electrokinetic field if the potential gradient is properly adjusted to eliminate severe leaf damage.

## ASTROPHYSICS

### Equatorial Angle Distribution between the Electrons captured in the Outer Van Allen Radiation Belt

FROM the measurements registered by *Explorer VI* in the outer Van Allen radiation belt, C. Y. Fan, P. Mayer and J. A. Simpson<sup>1</sup> succeeded in determining the number of particles which, in their longitudinal motion between two magnetic mirrors, cross the equator with a given pitch angle. In the polar diagram (number of particles versus equatorial pitch angle,  $\chi_e$ ) obtained by those authors a maximum exists for the equatorial pitch  $\chi_e = 35^\circ$ . This maximum has a sort of dynamical stability, because it is restored after a magnetic storm. In fact the authors observed a perturbation of the magnetic field, which shifted the maximum from  $35^\circ$  to  $48^\circ$ , but the value  $\chi_e = 35^\circ$  was resumed in spite of the fact that the number of electrons with a given velocity  $v$  was changed by a factor about 3.8.

The trajectories corresponding to  $\chi_e = 35^\circ$  possess some properties worthy of note. Considering the geomagnetic field as produced by a dipole, and using Alfvén's perturbation theory<sup>2</sup>, we can write the following equation for the angle  $\chi$  between the velocity  $v$  and the magnetic field  $H$ , as a function of the magnetic latitude  $\varphi$ :

$$\cotg \chi = \frac{v_{\parallel}}{v_{\perp}} = \sqrt{\frac{H_i}{H} - 1} = \sqrt{\frac{\eta_i}{\eta} - 1}$$

where

$$\eta = \frac{\sqrt{1 + 3 \sin^2 \varphi}}{\cos^2 \varphi}$$

The index  $i$  is related to the quantities calculated for the mirror point. Taking  $\varphi = 0$ , we find a relation between the equatorial pitch  $\chi_e$  and the latitude  $\varphi_i$  at the mirror point:

$$\cotg \chi_e = \sqrt{\eta_i - 1}$$

Moreover, the inclination  $\psi$  of  $H$  on the equator and the latitude  $\varphi$  are related by the formula:

$$\tan \psi = 1/3 [\cotg \varphi - 2 \tan \varphi]$$

The guiding centre of the particle performs its motion as a material point bound to a line of force of the geomagnetic field and is reflected at the mirror points. When  $\chi_e = 35^\circ$ , according to the formulae (Figs. 1 and 2), the mirror points lie near the magnetic latitude

Fig. 2

$\varphi = 35^\circ$ , where the magnetic field is parallel to the magnetic equator and where the dipole equivalent to the gyrating particle is perpendicular to the terrestrial dipole. So the axis of the gyrating particle oscillates at  $180^\circ$  in a half longitudinal period. Moreover, the mirror points coincide with the points of the line of force where the distance from the magnetic equator attains its maximum.

The latter circumstance suggests the existence of a repulsing force from the equator; but the question is not

Fig. 1

easy to deal with from the dynamical point of view. The quasi- (but not exact) coincidence could be a result of the approximation, both theoretical and experimental, or perhaps an essential feature of the phenomenon.

### Polarization Effects on the Profile of the H $\beta$ Line in the Light from the Star $\gamma$ Ursa Majoris

DURING February 1965 we observed some absorption lines in the spectra of several stars in orthogonal planes of polarization. The measurements were made with a photoelectric grating spectrometer<sup>1</sup> to which a rotatable 'Polaroid' had been added after the exit slit. The instrument was used at both the Newtonian and Cassegrain foci of the 48-in. telescope of the University of Padua's Observatory at Asiago, Italy.

Differential polarization effects across the absorption lines were sought by looking for departures from the instrumental polarization curve as the spectrometer was scanned.

Ohman<sup>2</sup> has shown that, in the case of rapidly rotating early-type stars, variations of polarization might appear across the absorption lines, and that, for a simple model, the degree of polarization might attain 0.8 per cent at the centre of the profile.

Considerations of the photometric accuracy required to measure an effect of this size make photographic spectrometry unlikely to succeed. However, calculations showed that polarizations of this order might just be detected by the instrument mentioned here, using a 1-10-sec integration time, provided the stars were brighter than 6th magnitude.

Observations of five stars were made at the Newtonian focus, the Cassegrain not being normally available for auxiliary instruments. As a result of a preliminary analysis, it seemed that  $\gamma$  (A0 ve, 2.5) and  $\eta$  (B3, 1.9) Ursa Majoris were worthy of further investigation. We were extremely fortunate in having the Cassegrain focus made available to us and decided to observe  $\gamma$  Ursa Majoris, it being the more suitably placed star at the time of observation.

Of the ten 1-Å resolution scans taken of the H $\beta$  line of this star, six were taken with the 'Polaroid' transmission axis perpendicular to the exit slit and four with it parallel to the slit. Ratios were formed of the corresponding ordinates of these two sets. The smooth change of this ratio with wave-length represents the variation of the overall instrumental polarization. However, in the neighbourhood of the H $\beta$  absorption, there are marked deviations from this smooth curve. It can be shown that if  $R(\lambda)$  represents the ratio of corresponding ordinates from orthogonal scans at wave-length  $\lambda$ , and  $R_*(\lambda)$  the ratio which it is assumed would have been obtained in the absence of source polarization (that is, interpolated values from the smooth curve), then:

$$P(\lambda) = \frac{R(\lambda) - R_*(\lambda)}{R(\lambda) + R_*(\lambda)}$$

where  $P(\lambda) = p(\lambda) \cos 2\varphi(\lambda)$ ,  $p(\lambda)$  being the degree of polarization and  $\varphi(\lambda)$  the angle formed by the direction of the polarized component of the light from the source and the transmission axis of the 'Polaroid'. The value of  $p(\lambda)$  can only be separated from  $P(\lambda)$  if the absolute instrumental polarization is known. Values of  $P(\lambda)$  were evaluated at 1.5-Å intervals across the line. Both the H $\beta$  profile and  $P(\lambda)$  are shown in Fig. 1. The values of

Fig. 1

$P(\lambda)$  are the means of the data and corresponding standard deviations are shown by the bars.

We conclude that:

(1) A differential polarization effect has been observed in the region of the H $\beta$  line in the light from  $\gamma$  Ursa Majoris. Since  $p(\lambda) > P(\lambda)$ , the differential polarization across the line must be at least 5 per cent. The magnitude of the effect is surprisingly large if the processes suggested by Ohman<sup>2</sup> are occurring. A variation of polarization of this magnitude should just be detectable by photographic spectrometry and, in this connexion, it is interesting to note that Ohman<sup>2</sup> found 'faint' polarization effects in the H $\gamma$  line of  $\beta$  Lyrae.

(2) The angle  $\varphi(\lambda)$  must have been different from  $\pi/4$  since the effect was observed. If  $\varphi(\lambda)$  is independent of  $\lambda$  over this region, then the form of  $p(\lambda)$  and the line profile exhibit the same asymmetry.

## PHYSICS

### Narrow Spectral Emission from a Passively Q-spoiled Neodymium-glass Laser

THE spectral behaviour of the Nd-glass laser has recently attracted much attention. Normally the output of the Nd-glass laser consists of a broad band of wave-lengths (approximately 50 Å wide) composed of hundreds of lines centred about 1.06  $\mu$  (see Fig. 1A). This structure has been described in detail by Snitzer<sup>1</sup>. Time-resolved spectra<sup>2,3</sup> and investigations of the pumping energy dependence of the output band-width<sup>4</sup> all may be interpreted on the basis of inhomogeneous behaviour of the Nd<sup>3+</sup> emission. The purpose of this communication is to report the efficient generation of a single narrow spectral line from a giant pulsed Nd<sup>3+</sup> glass laser by passive Q-spoiling.

Fig. 1. Spectral emission of  $\text{Nd}^{3+}$ -doped glass. A, Conventional emission; B, passively Q-spoiled emission. Wave-length increases to the left. The line-width in this figure is slit-limited.

The experiments were carried out with a  $\frac{3}{8}$  in.  $\times$  4 in. Corning glass rod. Q-spoiling was accomplished using a reversibly bleachable polymethine dye absorber<sup>4</sup>. In conventional non-Q-spoiled laser operation at energy inputs approximately 10 times threshold, outputs of 5 joules were obtained. Introduction of the Q-spoiling dye resulted in 0.5 joule (50 MW peak power) giant pulses of 10 nsec duration with remarkably narrow spectral width of 0.02 Å. Energies were measured calorimetrically and, in order to ensure that only a single giant pulse was obtained, each shot was monitored with a fast-rise Korad KD1 photodetector.

The spectra of conventional laser emission and passively Q-spoiled laser emission as observed with a 3.4 metre Jarrell-Ash spectrometer are shown in Figs. 1A and 1B. A Fabry-Perot interferometer was used for line-width measurements. The wave-length of the single narrow line obtained with each giant pulse varied between 10,600 Å and 10,624 Å. However, the line-width as measured with the Fabry-Perot interferometer was consistently observed to be  $< 0.02$  Å.

This result is noteworthy, in that the results of previous workers<sup>1-3</sup>, which may be interpreted on the basis of inhomogeneous behaviour of the  $\text{Nd}^{3+}$  emission, need to be contrasted with the present results which imply homogeneous behaviour to the extent that cross-relaxation within the band exists with characteristic time less than  $10^{-8}$  sec. We have observed similarly narrow spectral output from ruby lasers Q-spoiled with bleachable dye<sup>4</sup>, bleachable glass, or semi-conductor mirrors.

We thank O. R. Duncan for aid with the spectroscopic measurements and H. Kimura for preparing the Q-spoiling dye.

### Thiometallates of the Group-eight Metals

Rhodium III, palladium II, iridium III and platinum IV form simple thiometallates. There is some evidence that iron II, cobalt II, nickel II, ruthenium and osmium (both possibly IV) also form such compounds. Palladium, platinum and iridium also form polythiometallates.

Several thiometallates are listed in the literature<sup>1-3</sup> for the group-eight metals:  $\text{Na}_2\text{PdIVS}_4$ ,  $(\text{NH}_4)_2\text{PdS}_{11}$ ,  $\frac{1}{2}\text{H}_2\text{O}$ ,

$(\text{NH}_4)_2\text{PtS}_{11} \cdot 2\text{H}_2\text{O}$  and  $(\text{NH}_4)_2\text{IrS}_{11}$ . Thiometallates based on the simpler metallates are also known for many adjacent transition metals, for example,  $\text{Na}_2\text{VS}_4$ ,  $\text{Na}_2\text{MoS}_4$ ,  $\text{Na}_2\text{CuS}_4$ , etc., but very little else is known about them except the conditions for the precipitation of sulphides in chemical analysis<sup>4,5</sup>. If the common chloro-acids of ruthenium, osmium, rhodium, iridium, palladium, and platinum are dissolved in sodium carbonate or hydroxide, treated with hydrogen sulphide, and the solution filtered, yellow, brown, or red solutions are formed which on acidification deposit the following sulphides:  $\text{RuS}_2$  at pH 9.6,  $\text{OsS}_2$  at pH 0,  $\text{Rh}_2\text{S}_3$  at pH 0,  $\text{Ir}_2\text{S}_3$  at pH -0.2,  $\text{PdS}$  at pH 0, and  $\text{PtS}$  at pH 0. On partial acidification, sodium thionitrate gives a deep red solution at pH 4, which might be the free acid.

Hofman and Hochstetler and Lebedinaki *et al.* (refs. 2-5) used ammonium polysulphide saturated in sulphur when preparing their compounds. If less thionated ammonium polysulphide is used, similar solutions are obtained which give brown solids such as  $(\text{NH}_4)_x\text{PtS}_z$ , where  $x$  is 9.1, 9.6, 10.0, 12.1 or 13.8. Acidification of such solutions gives hydrogen sulphide, the normal metal sulphide, and free sulphur. Palladium and iridium were similar, but due to insufficient material only the platinum compounds were fully characterized. Similar experiments were carried out using sodium hydrosulphide. As this compound tends to oxidize to polysulphides, etc., in air, it was prepared under oil, and crystallized as shining white needles, which were redissolved to make a saturated solution. When this was reacted with sodium hexahydroxyplatinate IV or chloroplatinate IV, hydrogen sulphide was evolved. The resultant golden brown solutions on evaporation at room temperature in vacuum gave brown solids analysing as  $\text{Na}_2\text{PtS}_4$ : found 29.35 per cent S, theory 28.6 per cent. Due to the small quantity of material available, only rough analyses could be made for platinum, but these indicated a three to one sulphur to platinum atomic ratio. Sodium hexachloroiridate III and tetrachloropalladate II gave similar deep red solutions, but without evolution of hydrogen sulphide. On vacuum evaporation, these gave small quantities of brown powders. The palladium complex was much more soluble than the other two. Unfortunately these powders could not be purified without partial decomposition to sulphides, as indicated by analyses for metal above that for thiometallate, and low sulphur figures. However, approximately stoichiometric preparations indicate that the complexes are probably  $\text{Na}_2\text{Ir}(\text{SH})_6$  and  $\text{Na}_2\text{Pd}(\text{SH})_4$ , analogous to the hydroxy compounds. The difference from platinum is in the lack of hydrogen sulphide evolution.

It is evident from the foregoing results that the multi-sulphur compounds are formed by replacement of other anionic ligands by polysulphide groups as was postulated by Sidgwick<sup>6</sup>. Even when freshly made, the corresponding metal sulphides are very difficult to dissolve in sodium hydrosulphide, to form the thiometallates. It therefore seems probable that these salts are made by direct substitution rather than by precipitation and resolution.

If iron II or III, or cobalt II, or nickel II carbonate complexes are saturated with hydrogen sulphide, very unstable simple thiometallate solutions can be made, but they are too unstable to be isolated as solids. As both the iron valences give bluish solutions of the same hue, and both give iron II salts on acidification, they are presumably both two-valent. The cobalt and nickel solutions were both golden brown. No cobalt III solution could be made; cobalt III carbonates gave only the two-valent sulphide. Attempts to prepare thiocobaltate II by the action of sodium hydrosulphide on sodium cobaltate II gave cobalt sulphide, and a pale yellow solution containing only traces of cobalt, which may even have been colloidal sulphide. It is interesting to note that iron has the least stable thiometallate, and cobalt the most stable for these three elements. This is reflected in the relative

instability of the ruthenium compound, and the stability of that formed by iridium.

### True Stress to Fracture and Hyper-velocity Crater Depth

SERIOUS discrepancies and considerable variations have been observed in the numerous empirical, semi-empirical, and theoretical equations which have been proposed to describe craters formed in metal targets as a result of hyper-velocity impact<sup>1</sup>. These inconsistencies in the mathematical models can be attributed to a paucity of precise engineering data and to a basic disagreement about the mechanism of impact. One group of experimenters has attempted to relate the extent of hyper-velocity damage to the mechanical properties of the impacted target; another group has stressed the hydrodynamic model of cratering.

We have observed that the hyper-velocity impact force per crater surface area can be correlated to the true stress to fracture of the target material with the equation  $d = \left(\frac{mv^2}{4\pi s}\right)^{1/3}$ , where  $d$  is the depth of the hemispherical crater,  $m$  and  $v$  the projectile impact mass and velocity, respectively, and  $s$  the true stress to fracture. The applicability of the correlation of impact force with this mechanical property is shown in Table 1 for the impact condition of both similar and dissimilar materials. A representative sampling from 207 experimental points is given. Six types of aluminium alloys and oxygen-free high-conductivity copper were used as target materials. Spherical projectiles of glass, nylon, aluminium, copper and lead<sup>2,3</sup> with a mass range from 0.047 to 1.265 g were accelerated in vacuum with a light gas to impact velocities in the range from 3.66 to 9.35 km/sec. True stress to fracture data were obtained by the experimental method devised by J. Nunes and F. R. Larson<sup>4</sup>.

It must be stated that the proposed equation for crater formation, involving the true stress to fracture of the target material, permits the prediction of the crater depth, as observed from the excellent concordance between experimental and computed values summarized in Table 1. We recognize that other forms of energy dissipation are

operative: radiation, lip formation, highly strained volume element surrounding the crater, etc. In addition, the true stress to fracture is an average value since it is a parameter sensitive to such factors as composition, grain size, grain orientation, inclusions, cracks, etc. We selected this parameter, however, since 'true stress' denotes the actual stress corresponding to the force and area measured at the same time.

The proposed model appears to be valid for ductile aluminium which is a body-centred cubic material. Under the imposed experimental conditions the shear stress applied is considerably greater than the target shear strength and the target reacts as if there were a time delay for plastic deformation. This time delay should be longer than the period of time for crater formation. The material flows not hydrodynamically but according to metallurgical properties, without strain hardening; that is, once the material flows it will continue until the energy in the material has decreased below a critical, or threshold, level or until the time delay for strain hardening is attained. The process of flow and fracture ceases when the energy in the target has decreased below the energy under the true stress-strain curve obtained with strain at normal strain rates.

We are in the process of further testing the proposed cratering model by impacting an aluminium alloy at room temperature, where it behaves in a ductile fashion (20 per cent reduction in area), and at a temperature of -196° C, where it behaves in a brittle fashion (4 per cent reduction in area). In addition, we are impacting a face-centred cubic target, which should be more strain-rate sensitive than the present group of targets.

### GEOPHYSICS

#### Power Spectrum of Sporadic-E at Wilkes and Byrd Stations, Antarctica

Chivers and Hargreaves<sup>1</sup> have reported the occurrence of quasi-periodic variations in the time series of high-frequency radiowave absorption at high-latitude conjugate locations. The absorption is of the type known as 'auroral zone absorption' (Type II) which is thought to result from ionization in the upper D-region produced by keV energy electrons dumped from, or freshly accelerated in, the outer Van Allen region of the magnetosphere. We report here periodic variations of the ionospheric sporadic-E layer in Antarctica with similar frequency and latitude

Table 1. SUMMARY OF IMPACT CRATER DATA

characteristics. These results may have considerable importance in suggesting a theory of high-latitude sporadic-*E*.

The sporadic-*E* critical frequency ( $f_oE_s$ ) has been scaled at 15-min intervals from the original ionogram film taken at the Antarctic stations, Wilkes and Byrd. Each sample consists of five consecutive days and was selected on the basis of visual inspection of the hourly tabulated values to insure that a fairly continuous time series of occurrence existed. The samples were chosen from local winter (July and August 1957 and 1958) in order to reduce the possibility of spurious results introduced by diurnal variation of *D*-region absorption or the regular

*E*-layer. In addition to computing the hanned spectral estimate for each sample by the method of Blackman and Tukey<sup>3</sup>, spectral estimates were computed from the mean of the autocorrelation functions of five samples at each station. We present in Fig. 1 the results for single five-day samples at Byrd and at Wilkes; the five-sample-average spectral estimates possess the same characteristics. Error bars indicate the 90 per cent confidence interval.

In addition to a low-frequency peak resulting from the diurnal modulation, statistically significant high-frequency spectral peaks are noted in each sample. The principal (and secondary) periods are: Byrd, 2.2 h (1.1 h); Wilkes, 1.7 h (2.4 h). No significant variation was noted above 1 cycle per h and the data are not presented. In view of the rather large amplitude of the principal (2.2 h) peak at Byrd, the secondary peak may simply be a harmonic. This may not be said of the spectrum at Wilkes.

We suggest that these periodicities are real and that they may be similar to the absorption variations noted by Chivers and Hargreaves. Without entering into a detailed discussion of the relative merits of various production mechanisms, we suggest consideration of the magnetospheric time-of-flight spectrometer effect<sup>4</sup>. An impulsive source of keV energy electrons, which is localized in longitude, will produce distant, quasi-periodic, ionospheric effects (on the same *L*-shell<sup>4</sup>) which may be characterized by the longitudinal magnetospheric drift time of a mean bombarding energy. Such a mechanism would also result in quasi-periodic behaviour of auroral zone absorption.

### Attempted Synthesis of the Epigenetic and Syngenetic Theories of Secondary Ore-body Formation

At the present time there are two rival theories of the formation of many copper deposits, and many other secondary ore-bodies are described as anomalous<sup>1</sup>. Mohr has suggested that a synthesis of these two theories might one day be possible<sup>2</sup>.

From the point of view of geochemical transportation of heavy metals, there are two kinds of rivers: those that tend to develop a pH of greater than seven, and those that do not. The latter are relatively well known, and have familiar chemical reactions. The former are complicated in that most heavy metals must be complexed as anions in order to remain in solution. While such ligands as fluoride, tartrate, glycinate, and other organic acids derived from vegetation may sometimes form such soluble complex metallates, by far the commonest such ligand is the carbonate ion itself. Many such carbonate-complexes are described in the early literature, and while the stability often decreases with falling pH, some, such as carbonatocobalt II, can only be prepared in the presence of bicarbonate ions. In almost every case, solutions only just alkaline will not carry large quantities of heavy metals; they will, however, carry such metals. Table 1 lists the various ways that metals may exist in carbonate waters, and Table 2 shows the effect of carbonate concentration on the transportation and stability of copper and other metals as carbonate complexes. Examination of alkaline Ethiopian rivers shows that they

first two being metabolized by plants and soil organisms. In confirmation that carbonic acid will form sodium bicarbonate, samples of basalt from the Entoto ridge in Addis Ababa were leached with saturated carbon dioxide water (mineral or soda water), and the pH measured regularly; after about one month, the pH had changed from about 4 to 8, and the presence of bicarbonate was confirmed by titration. The residues left from the basalt closely resemble the common black clays of Ethiopia. In control experiments using pure water and aqueous sodium chloride, the final pH was slightly above 7. Sodium carbonate can be formed from the bicarbonate, possibly to a small extent by a continuation of the above sodium exchange process, but definitely by contact with hot igneous rocks as at the hot springs along the Ethiopian Rift (those around Lake Shalla actually emit carbon dioxide along with boiling water containing dissolved sodium carbonate and bicarbonate). Vegetation can also form carbonate by metabolizing carbon dioxide. Algae grown in typical Ethiopian river and lake waters containing sodium bicarbonate can raise the pH to well over 9, and one strain (isolated from Green Lake, Debra Zeit, alias Bischoftu, by R. B. Baxter) reached pH 12 when guarded against atmospheric carbon dioxide. Not all igneous rocks give rise to alkaline water, nor are all the rivers rising on basalt and similar basic rocks alkaline. So far a few acidic rivers have been found in Ethiopia, but these have all been associated with pockets of limestone, or marshes where the water is shielded from the underlying basalt by clay. Even these rivers contain some sodium bicarbonate, and may change to alkaline in their less accessible lower reaches.

Basic igneous rocks are often closely associated with sulphide rocks\*. This is not surprising if the denser basalts and sulphides are associated with the deeper layers of the Earth's structure. From the foregoing it is evident that alkaline waters will produce 'anomalous' ore-bodies (see Mohr<sup>2</sup> for a discussion of two cases) and that such waters are associated with certain types of volcanic activity. It is therefore probable that both volcanic and weathering action are necessary to form these ore-bodies. The volcanic activity is necessary to form the basalts and other basic rocks which later weather to make alkaline carbonate waters, and also to bring up the primaevial sulphides, etc., which are later leached and if necessary oxidized by the alkaline waters. Subsequent deposition by hydrolysis, evaporation or precipitation from these carbonate-complexes leads to secondary ore-body formation. Thus both syngenetic and epigenetic processes are essential to the formation of these deposits.

### An O<sup>+</sup> Layer at 1,200 km

THE determination of the ionic composition of the topside ionosphere by means of the ion energy spectrometer on *Ariel I* (1962 *omicron*) and the analysis of some of the data have already been reported<sup>1</sup>. Recently, we have analysed data obtained over the early summer of 1962 during days 117–181.

The broad features follow and amplify the diurnal and latitude variation already indicated and will be reported in greater detail elsewhere. The purpose of this com-

Fig. 1. Observations of the percentage of O<sup>+</sup> in the ionosphere as a function of altitude. The horizontal lines connect the quantiles of the distributions of the observations when divided into 50-km height intervals. The curve shows the composition calculated on the assumptions of diffusive equilibrium and equal concentrations of O<sup>+</sup> and He<sup>+</sup> at 950 km.

munication, however, is to direct attention to an unforeseen effect.

Fig. 1 shows the percentage of oxygen ions as a function of altitude in the afternoon between the hours 1200 and 1700, during which O<sup>+</sup> and He<sup>+</sup> are predominant and the relative concentrations are only changing slowly with time. The points apply to geographic latitudes in the range 10°–40° N. It will be noticed that a region of increased percentage concentration of O<sup>+</sup> appears in the afternoon at great heights. The raw data have been carefully examined to ensure that this effect is not introduced by systematic variation of other parameters with satellite altitude, and while the data will not allow a complete separation of effects due to latitude season and local time and possible instrumental effects due to attitude (it is known that the sensitivity of the spectrometer is attitude dependent), there is no hint either from theory or experiment that the effect can be accounted for in any other way than a genuine departure from hydrostatic equilibrium.

Similar experiments on the satellite *S.48* (1964 *SLA*) and on the forthcoming satellite *S.30A* (*D.M.E.-A.*) may be expected to provide further data. In the meantime, we wish to direct attention to the geophysical significance of the data we have.

Hanson<sup>2</sup> has shown that at heights above about 800 km the ion temperature will be close to the electron temperature. The curve in Fig. 1 is the theoretical percentage of O<sup>+</sup> calculated under the following assumptions—diffusive separation of He<sup>+</sup> and O<sup>+</sup> under hydrostatic equilibrium; ion temperature 2,000° K;  $g$  (constant) = 750 km/sec; 50 per cent O<sup>+</sup> at 950 km.

These assumptions give a scale height for the O<sup>+</sup>/He<sup>+</sup> ratio of 184 km which is probably an upper limit for the greater altitudes and is certainly too large for the lower altitudes in view of the lower ion temperature there and the greater value of  $g$ . Even with this upper limit for the likely scale height, about 90 per cent of the points above 1,150 km are well above the theoretical value, and it is clear that a theoretical composition curve based on hydrostatic equilibrium cannot be made to fit the data.

It is, of course, not possible to obtain a vertical profile of the ion mass spectrum from a single satellite pass. Instead, reliance must be placed on the slow change of orbit parameters. The large scatter of the points is an indication of the considerable variability of the composition of the topside ionosphere from day to day, but the trend is unmistakable in spite of the scatter.

If we consider how a relatively high concentration of  $O^+$  could be maintained at 1,200 km it is clear we have a dynamic situation in which the ionization as a whole must be rather closely in hydrostatic equilibrium in the gravitational and electric field; but a departure from a static equilibrium distribution of diffusive separation may exist as a result of an opposing flow of helium and oxygen ions. Ion-ion collisions ensure that the temperature of the two ion species cannot be very different and that the relevant diffusion coefficient is much smaller than for the ions in the neutral gas.

A mere thermal expansion of an isothermal ionosphere in hydrostatic equilibrium, due to the diurnal heating, would not involve the flow of one ion species through another. The departure from hydrostatic equilibrium, therefore, requires that the net production of ions be able to maintain the concentration gradient. Either the production of  $O^+$  at great heights or the production of  $He^+$  near the  $F$ -region maximum would give an effect of the sign observed; but the latter is ruled out on the ground that it would require a much larger percentage of  $He^+$  near 400 km than at night, which is the opposite to what is observed. It seems, therefore, that we must postulate a substantial production of  $O^+$  at great heights.

The day-time thermal expansion of the atmosphere results in the concentration of neutral oxygen changing from its night-time value at great heights by a very large factor, so that at 850 km its concentration in the afternoon is about equal to that of helium. Oxygen may, therefore, be expected to play a much more important part in ionization production in the afternoon. The results suggest that helium ions diffuse upwards through an opposing falling stream of oxygen ions. A calculation shows the ion-ion relative velocity of the stream to be about  $0.1 \text{ km sec}^{-1}$ . The downward flux of oxygen ions at 950 km is about  $2 \times 10^7 \text{ cm}^{-2} \text{ sec}^{-1}$ , and the ionosphere above this height has a scale height of about 400 km leading to an oxygen ion loss rate of  $0.5 \text{ cm}^{-2}$ .

The photo-ionization rate alone is insufficient to maintain this loss, and is too small to build up this  $O^+$  concentration in the preceding hours of daylight.

The reaction  $O + H^+ \rightleftharpoons O^+ + H$  is in a state of thermal unbalance since  $T_e \sim 2T_{\text{gas}}$ , which may favour the forward direction, but even then its rate seems inadequate. A further possible source of  $O^+$  production might be energetic streams of electrons<sup>1</sup>, but here again the fluxes so far observed seem too small.

It is possible that a combination of these factors is sufficient to account for the  $O^+$  production, especially in view of the rather large uncertainties in many of the quantities and parameters needed to evaluate the rates.

## GEOLOGY

### Geology of Part of the Southern North Sea

WORK on the geology of the floor of the southern North Sea, under a Department of Scientific and Industrial Research grant to the University of Hull, is now in its second year. It has been carried out with a chartered 110-ft. Diesel trawler, using a 10-cwt. gravity corer for sampling, and a continuous reflexion profiler for recording structures in the rocks below the sea bed and the thickness of superficial deposits. The profiler consists of a 1,000 W-sec Edgerton boomer and a directional hydrophone and amplifier of the type developed by the National Institute of Oceanography<sup>1</sup>. It gives a penetration of about 900 ft. below the sea-floor in favourable circumstances.

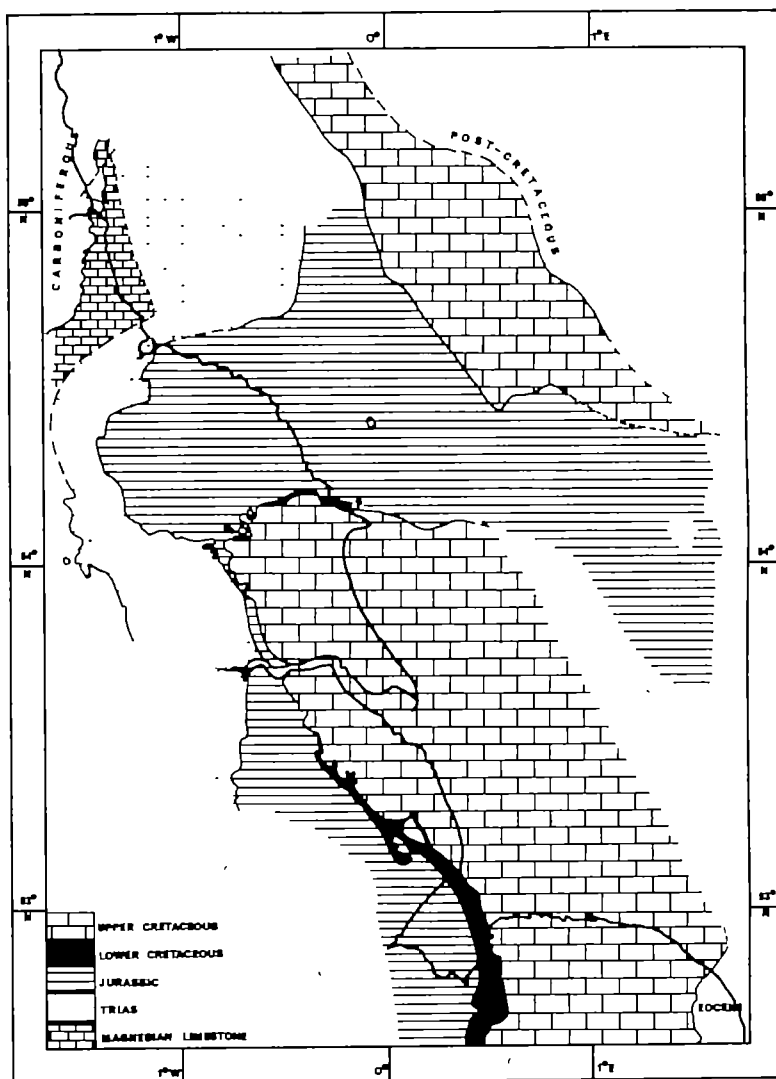

Fig. 1

The extent of the outcrops of pre-Quaternary systems proved so far is shown in the map (Fig. 1). All the outcrops have been proved by sampling, while many details of the boundaries have been taken from continuous reflexion traverses. The outcrop of the Magnesian Limestone offshore is based on the continuous reflexion profiling and offshore borings by the National Coal Board<sup>2,3</sup>; we have not worked in this area. Land outcrops have been simplified from the map of the Geological Survey, and the western limit of the Eocene in Norfolk is taken from

Downing<sup>4</sup>. The outcrop shaded as Trias includes all rocks between the Magnesian Limestone and the Jurassic.

South of Flamborough Head the pre-Quaternary rocks are covered by an almost unbroken mantle of Pleistocene deposits, but they can be sampled in the 'pits' where erosion has breached the Pleistocene cover. Chalk has been proved in the Inner Silver Pit, the channel leading into the Wash, and Codling Hole (the deep trench on the western side of Outer Dowsing Shoal).

Between Flamborough Head and the mouth of the Tyne Mesozoic rocks are extensively exposed on the sea-floor, and have been sampled at intervals of a few miles. The detailed stratigraphy and structure of this area is being worked out. The Jurassic rocks off north-east Yorkshire are gently folded, with dips up to about 4° and a prevailing strike north-north-west. A dome at 54° 22' N., 0° 7' W., is responsible for a small inlier of Trias. The Jurassic rocks appear to extend eastwards towards the Outer Silver Pit. In the western part of this pit at 54° 08' N., 1° 26' E., is another outcrop of Trias known to fishermen as the Red House.

The outcrop of Chalk north-east of the Yorkshire coast has been sampled in numerous places along its edge; north-eastwards it passes under Pleistocene and superficial deposits. An outcrop of post-Cretaceous rocks beneath these deposits has been inferred from continuous reflexion records.

Pleistocene rocks in the area consist mainly of boulder clay attributed to the Last Glaciation. In the Inner Silver Pit at about 53° 27' N., 0° 41' E., marine silts of probable Pleistocene age have been sampled. They are believed to underlie the boulder clay<sup>5</sup>.

Superficial deposits of any thickness are of restricted occurrence. An accumulation of sand, up to 70 ft. thick, extends from the south-western part of the Dogger Bank to within 15 miles of Flamborough Head. There are many sand waves in this area<sup>6</sup>. North of this area much of the Chalk and the post-Cretaceous rocks are covered by superficial deposits which have not been studied in detail. South of latitude 53° 35' N. are a number of sand banks. Outside the areas just mentioned superficial deposits are generally thin, often no more than a few inches thick. Isolated sand waves and groups of sand waves occur locally.

The Inner Silver Pit is a closed basin, eroded through Last Glaciation boulder clay into Pleistocene marine silts and clays and Chalk. It appears to be of geologically recent origin. It cannot be a submerged river valley and has possibly been cut by tidal scour<sup>7</sup>.

### Differentiation of Alkali Basaltic Magma

In recent years the attention of petrologists has been directed towards understanding the behaviour of basaltic magma in the light of experimental data. While observational and experimental results have progressively enriched our ideas on the reaction principles in sub-alkaline basic magma, "the possible and necessary reactions" in alkali basaltic magma series have been overlooked<sup>1</sup>. The broad petrographic differences between tholeiitic and alkali basaltic series obviously reflect the possible deviations in the reaction processes in the two magma types. The nature and cause of such deviations in reaction

relations will be discussed elsewhere. The normal course of fractionation of alkali basaltic magma leads to the development of an undersaturated alkalic liquid where the undersaturation is inherited from the parent magma. Such late liquids are normally more alkaline than similar products from tholeiitic magma as the mafic phases in alkali basaltic magma invite greater amounts of calcium at the expense of plagioclase, causing a relative enrichment of soda in the residue. Accordingly the derivative of the alkali basaltic magma descends down to the lower quadrilateral in Petrogeny's Residua system<sup>2</sup>, though the exact degree of undersaturation will largely depend on the bulk composition of the initial parent magma and the compositions of the separated mafic phases. Even if the liquid comes down just below the feldspar join in the said system, fractionation of alkali feldspar leads to a decrease of silica:alkalis ratio in the liquid and thus its undersaturation is augmented.

The association of acid derivatives with undersaturated alkaline basic rocks, however, poses an interesting problem. Such co-existence of members with opposite characters has been interpreted by invoking various mechanisms<sup>3,4</sup>, some of them conjectural. It is relevant to note that the promising postulation of Bowen<sup>5</sup>, bearing on this problem, did not receive adequate support either in the field or in the laboratory. It is known now from experimental studies that the liquids on the feldspar join have their vapours slightly oversaturated in silica<sup>6</sup>. Further, some alkali feldspars are shown to have excess silica in their constitution<sup>7</sup>. Obviously, loss of hydrous vapour during fractionation or separation of silica-rich alkali feldspar will have a significant role in moulding the compositional variation of the liquid and causing an association of feldspathoidal rocks with those having excess silica.

An alternative trend of differentiation of the alkali basaltic magma seems to be a promising mechanism for developing acid derivative out of the undersaturated parent magma and thus bringing chemically divergent members together in space and time. This alternative course of diversification of alkalic basic magma will be manifested when aluminium is present in considerable amounts in the constitution of the separated mafic phases, favoured by high water pressure<sup>8</sup>. As aluminium is accommodated in the structures of the mafic silicates (by diadochic replacement of Si) at the expense of plagioclase—the remaining liquid is enriched in silica and depleted in alumina. Such a mechanism having experimental support<sup>1</sup> may ultimately produce a peralkaline siliceous liquid. The present discussion, however, does not overlook the possibility that assimilative reaction of feldspathic liquid with carbonates may cause an association of rock types having diverse characters. The reactions observed in the crucible<sup>9</sup> are envisaged as having occurred in Nature.

In Koraput, Orissa (Eastern India), successive emplacement of alkali gabbro-calcalkali syenite-perthite syenite-nepheline syenite, is a manifestation of crystallization differentiation of alkali basaltic magma in a plutonic environment<sup>10</sup>. These co-magmatic rocks represent another instance of the normal trend of differentiation of alkali basaltic magma where feldspathoidal syenite is found to be the ultimate derivative. Besides the above members in the suite there occurs a feldspar pegmatitic granite (alsakite) solely confined within the gabbro. The oversaturated rock containing small amounts of aegerine-augite occurs in irregular pockets and appears to have formed *in situ* within the gabbro. Detailed petrological investigation of the whole suite establishes the fact that the acid member does not lie directly on the liquid line of descent. There is also no field or laboratory evidence to suggest the origin of the granite by fusion of pelitic country rocks.

A remarkable mineralogical characteristic of alkali gabbro—the host rock for granite—is the profuse development of a brown sodicalcic amphibole<sup>11</sup> which, like others

of its type<sup>1</sup>, is undersaturated in character. Development of such amphibole at the expense of the plagioclase constituents was favoured by high water pressure<sup>11</sup>. The crystallization of such undersaturated amphibole in profusion played a significant part in moulding the composition of the residual liquid in a closed system. Because of the increasing degree of substitution of Si by Al in the structures of the mafic phases there was an accumulation of the former element and depletion of the latter in the residual liquid. Thus ultimately a peralkaline acidic liquid of moderately high temperature was formed interstitially and it developed local irregular pockets of quartz-poor hypersolvus granite within the alkali gabbro.

It should be pointed out that the trend of differentiation of alkaline basic magma will be greatly influenced by the relative distribution of Al and Si in the crystals and the liquid. If Si/Al ratio in the mafic crystals is higher than that in the magma, the liquid becomes depleted in Si relative to Al. A reversed relation favoured by high water pressure will cause the development of a slightly oversaturated liquid. Fractional crystallization of alkali feldspar in the two cases will respectively lead to further undersaturation and oversaturation of the residual magma. It is stressed that the distribution factor in a large measure controls the trend of differentiation of alkali basaltic magma and this in its turn is influenced by the prevalent water pressure. Fluctuations of water pressure may cause further complexity in the evolution of the magmas.

### Isotopic Composition of Strontium in a Variety of Rocks from Réunion Island

THE island of Réunion is situated some 375 miles to the east of Madagascar in the Indian Ocean. The isotopic composition of strontium (Table 1) has been determined in a suite of rocks ranging from basalt to quartz-bearing syenites. The investigation was undertaken to see whether or not variations in the isotopic composition of strontium were present in a wide range of rock types situated in an oceanic environment.

In the samples analysed no significant differences were observed although the rocks had differing Rb/Sr ratios. This is in general agreement with results obtained from Hawaii<sup>1</sup> and suggests that all the Réunion rocks could be derived from an area in the mantle below Réunion having a constant Rb/Sr ratio. The lack of any significant varia-

tion in the isotopic composition of strontium is of particular interest in the case of the potassium rich (5.12 per cent K<sub>2</sub>O) quartz syenite and indicates that this quartz-rich rock has been formed from an environment having an Rb/Sr ratio similar to that of the basic and ultra-basic rocks present on Réunion.

Four analyses of the Massachusetts Institute of Technology Elmer Amend shelf strontium standard circulated by Prof. Hurley gave an <sup>87</sup>Sr/<sup>86</sup>Sr ratio of 0.7075 ± 0.002, which is slightly lower than that obtained by other laboratories. In order to compare these results with those obtained by other laboratories they should be increased by between 0.001 and 0.002. An error of ± 0.002 is placed on the measured <sup>87</sup>Sr/<sup>86</sup>Sr ratios and is a combination of instrument error and other errors, the major one of which is considered to be a function of the chemical purity of the strontium when placed on the filament. If the full value of inter-laboratory comparison is to be obtained by comparison with a strontium standard, this should consist of a rock powder rather than a pure strontium salt.

The results recorded here form part of a general survey of strontium isotopes, Rb/Sr, and K/Rb ratios of oceanic rocks, the full details of which will be published shortly. I thank Dr. B. G. Upton for providing the Réunion specimens.

### METALLURGY

#### A Strengthening Effect of High Hydrostatic Pressure on Grain Boundary Walls of a Polycrystalline Zinc

DURING investigations of dislocation behaviour in a polycrystalline zinc a number of interesting facts were found. (All experiments were performed at room temperature and specimens 6 mm<sup>2</sup> × 12 mm were machined from a commercially pure zinc cast of the composition shown in Table 1. Specimens were annealed at 350° C for 5 h and furnace-cooled to a grain size of American Society for Testing Materials micro-grain size No. 00 (except for one shown in Fig. 1 which was not annealed). The polishing and etching reagents for revealing grain boundaries and dislocations were similar to those used by J. J. Gilman<sup>1</sup>).

(1) Twin formation and the movement of grain and twin boundaries besides crystallographic glide are responsible for a large plastic flow of this metal during uniaxial stressing, creep, relaxation and fatigue testings, as is shown in Fig. 1.

(2) By the application of high hydrostatic pressure of the order of thousands of atmospheres, dislocations line up along grain boundaries. Twin formation is suppressed to a great extent and grain boundary movement is completely blocked. However, multiplication and movement of dislocations are still persistent and cause a plastic strain of the order of one ten-thousandth. Fig. 2 shows the build-up of dislocation walls along grain boundaries and dislocation line-ups in crystals with the application of hydrostatic pressure.

(3) Once the aforementioned structure of dislocations is formed the zinc specimen is greatly strengthened: the result of uniaxial compression tests showed that the stiffness was increased by 20 per cent when a specimen was pressure-treated at 3,000 atm. for 1 h. When an initial

## ENGINEERING

### Ultrasonic Grinding of Natural Graphite

FINE grinding of graphite is usually carried out in a mortar or in a ball mill. The reduction of the particle size proceeds rather slowly due to the lubricating action of the grain surfaces, and the ground crystals contain various kinds of lattice imperfections including stacking faults—the extent of the imperfections being subject to the period and method of grinding. Recently, Bacon<sup>1</sup> and others<sup>2-4</sup> studied this phenomenon, both using an electron microscope and X-rays. I myself carried out some experiments on similar lines with Madagascar graphite ground in a cell excited with ultrasonic waves. The original powder was 50–65 mesh graphite crushed in a mortar. The slurry containing the powder was treated with 20-ke/s, 150 V amp ultrasonic radiation in a cylindrical cell 26 mm in diameter. The slurry entered the cell through a pipe attached on the face of the cylinder and flowed out through another pipe attached on the opposite side, and it was circulated slowly with a gear pump. The ultrasonic power was supplied through the top of the cell which was the end plane of the oscillator horn. The height of the cell was adjustable. In the range of height from 1 to 10 mm the change of

grinding speed was not marked. The following media were used: Pure water, 1 per cent aqueous solution of tannic acid or detergent, glycerine, paraffin oil and dense bromoform (specific gravity 2.8). The bromoform seemed to have superior grinding powers, but was troublesome in extended use due to its corrosiveness and irritating vapour. The glycerine was found to be unsuitable for the purpose. Aqueous solution of tannic acid or detergent wetted the graphite particles, and the powder was uniformly dispersed after several passes through the cell. Crushing then proceeded continuously, although pure water did not wet it and the agglomerated powder floated on it for a long time without becoming dispersed in it. When ultrasonic vibration was applied in an open cell containing the slurry, for example by simply inserting the horn end in a beaker, the graphite particles were expelled from the horn and floated on the liquor surface even in water containing tannic acid or detergent. Paraffin oil was inferior to the aqueous solutions.

Under an optical microscope ultrasonically ground particles revealed flat glancing faces often exhibiting clear twin boundaries. The surfaces of particles ground in a mortar with a pestle were commonly rougher, showing close fringes of laminated steps on the basal plane. Apparently, ultrasonic treatment de-laminates each particle and removes surface roughness. Fig. 1 is a micrograph of the graphite particles obtained with an electron microscope operated at 60 kV. The particles had been ground in the cell for 50 h in 1 per cent tannic acid liquor. In the photograph, flake-like particles are seen gathering side by side, partially overlapping each other and transparent to the electron beam even in particles as large as 1  $\mu$ . Several black rod-like grains are presumably similar flakes orienting flat surfaces parallel to the electron beam. Comparing this with the electron micrographs published by Walker and Seeley<sup>5</sup>, it is clear that these particles are flakes de-laminated more uniformly than particles ground in a ball mill, and suitable for lubrication or surface coating.

Successive stages of grinding were examined with the powder camera (24 cm diameter) using CoK $\alpha$  radiation and the samples placed in cellulose tubes 0.8 mm in diameter. Fig. 2 shows the intensity curves of the diffraction patterns in a region in which the intensity is reduced to the true intensity from the microphotometer curves. The

Fig. 1

Fig. 2

lowest curve 1 is the original 50-mesh graphite, and curves 2, 3, 4, 5, 6 and 7 are the particles subjected to the ultrasonic grinding for, respectively, 1, 1.5, 3, 6, 12 and 50 h in 1 per cent tannic acid liquor. In Fig. 1 the lines (1010) are seen to be the same height. The rhombohedral lines (100) and (110) increase progressively with the grinding period as already reported by Bacon and others. A marked feature of the present patterns is the great increase in intensity of the rhombohedral lines although the line widths are relatively narrow. In the case of ball-mill grinding the (110) line almost disappeared, covered by the diffused hexagonal line (1011) when the intensity of the line (100) increased to the extent of the curves as shown in Fig. 2. In the present pattern the line appears clearly separated from its neighbours, and the present treatment has been found to produce the modification in a more perfect state.

## CHEMISTRY

### Primary Processes of Photo-oxidation of Aqueous Fe(II) Species

SOME years ago an investigation of the species produced in the photo-oxidation of aqueous reducing anions and cations was begun in these laboratories<sup>1</sup>. More recently, by using  $N_2O$  and other specific electron scavengers, it was shown that the primary process is one of electron detachment for  $I^-$  (ref. 2),  $OH^-$ ,  $Br^-$ ,  $Cl^-$  and  $SO_4^{2-}$  (ref. 3), and that the hydrated electron,  $e_{aq}^-$ , which is so formed has relative reactivities similar to those of the electron produced on absorption by water of ionizing radiations and is influenced by ionic strength in predictable ways. We have obtained similar results for the electron photo-detachment at 2537 Å from  $Fe^{2+}$ , but certain solutions containing  $Fe(ON)_4^{2-}$  show unusual effects which have caused us to re-examine this system carefully<sup>4</sup>.

Briefly, the phenomena observed on illumination of neutral or alkaline solutions of  $K_4Fe(CN)_6$  are explicable in terms of the primary act (1):

with geminate recombination of  $e_{aq}^-$  and  $Fe(CN)_6^{3-}$  which can be suppressed by sufficient concentration of an electron scavenging solute. If a hydrogen atom scavenger (isopropanol) is used, no hydrogen atoms are detected. If two solutes,  $S_1$  and  $S_2$ , are used, values of  $k(e_{aq}^- + S_1)/k(e_{aq}^- + S_2)$  agree with those obtained for the radiation chemically produced electron and are influenced by  $\mu$  in the expected manner, for example,  $k(e_{aq}^- + NO_2^-)/k(e_{aq}^- + N_2O) = 0.79 \pm 0.08$  (photochemical) and 0.72 (calculated from radiation chemical data<sup>5</sup>) when  $\mu = 0.04$  and  $t_1 = 6 \times 10^{-9}$  sec.

However,  $\log_{10} k(e_{aq}^- + NO_2^-)$  for the photochemical case increases proportionately to  $(2.3 \pm 0.4) \mu^{\frac{1}{2}}/(1 + \mu^{\frac{1}{2}})$ , whereas in the radiation chemical case the dependence on  $\mu$  is much less marked. This result can be understood if it is assumed that  $e_{aq}^-$  reacts with an  $NO_2^-$  ion while still within the relaxed ion atmosphere of the ferrocyanide ion from which it was ejected. Application of the theory of ionic reactions to this model predicts a linear dependence of  $\log_{10} k(e_{aq}^- + NO_2^-)$  on  $2.5 \mu^{\frac{1}{2}}/(1 + \mu^{\frac{1}{2}})$  under conditions where simplifying assumptions are possible.

When one of the solutes is  $H^+$  (that is, acidified solutions) different results are obtained. Thus, the rate constant ratios are normal for, say, solutions of  $La_4(Fe(CN)_6)_3$ ,  $k(e_{aq}^- + H^+)/k(e_{aq}^- + N_2O) = 1.55 \pm 0.1$ , but are abnormal for solutions of  $K_4Fe(CN)_6$ ,  $(\log_{10} (k(e_{aq}^- + H^+)/k(e_{aq}^- + N_2O)))$  computed from the dependence of  $\varphi(N_2)$  on the ratio of bulk concentrations of  $[H^+]$  to  $[N_2O]$  is equal to  $0.25 (\pm 0.1) + 2.8 (\pm 0.5) \mu^{\frac{1}{2}}/(1 + \mu^{\frac{1}{2}})$  when  $[H^+] \ll [Fe(CN)_6^{4-}]$ .

Moreover, if the hydrogen atom scavenger  $i$ -PrOH is present in addition to or instead of  $N_2O$ , the apparent quantum yield of the primary act identified as the limiting value of  $\varphi(N_2) + \varphi(H_2)$  at high scavenger concentration is less than 0.66 and diminishes with increasing acid concentration although such hydrogen atoms as are formed react at the expected relative rates with  $Fe(CN)_6^{4-}$ ,  $NO_2^-$  and  $i$ -PrOH.

These anomalies are only explicable in terms of the simultaneous primary acts (1)–(2) (dotted arrow denotes geminate recombination):

+

for which  $\varphi_2 \leq \varphi_1$  and  $\varphi_1 = 0.66$ .

The equilibrium constant  $[HFe(CN)_6^{3-}]/[H^+][Fe(CN)_6^{3-}] = 2.24 \times 10^4 M^{-1}$  and so conditions can be devised under which, although more than 95 per cent of the  $H^+$  is associated with  $Fe(CN)_6^{3-}$  as  $HFe(CN)_6^{3-}$ , about 75 per cent of the light is absorbed by the unprotonated ferrocyanide ion. The competition between  $N_2O$  and  $HFe(CN)_6^{3-}$  for  $e_{aq}^-$  emerging largely from process (1) can be investigated, and it is shown that  $k_2 = 0.1 k_1$  and that the effect of ionic strength on  $k_2$  is that expected from the Brønsted-Bjerrum theory of ionic reactions:

It follows from this mechanism that, with sufficient  $i$ -PrOH present to scavenge all the hydrogen atoms, increasing  $[H^+]$  should cause  $\varphi(H_2)$  first to increase as reaction (3) competes with the geminate reverse reaction (–1) and then to decrease as the primary act changes progressively from (1) to (2). This too has been observed.

Full details of this and related investigations are in the course of publication<sup>4</sup>.

### Action of Atomic Hydrogen on Ferri-Cytochrome c in Aqueous Solution

Atomic hydrogen is one of the simplest chemical reagents. Its structure can be described in exact theoretical terms. In aqueous solution it interacts only relatively weakly with the solvent. It is neutral and thus not influenced by ionic effects in its reaction with specific substrates. Therefore its reactions are of interest from the point of view of fundamental chemical kinetics in aqueous solutions. Recently, a method has been established for the investigation of the quantitative aspects of the reactivity of atomic hydrogen with various substrates dissolved in aqueous solutions<sup>1</sup>. Using a high-frequency electrode-less discharge to dissociate pure hydrogen gas into hydrogen-atoms and passing these under carefully controlled conditions into aqueous solution, it was shown that the reactive species is identical in its reactions with hydrogen-atoms produced by ionizing radiations or by ultra-violet light<sup>2</sup>. Therefore these reactions serve to elucidate also, independently, some aspects of the mechanism of the action of ionizing radiations or ultra-violet light on such systems. In this method, however, hydrogen atoms are the only reactive species present so that their specific action may be examined separately. The reactions of simple substrates (inorganic ions<sup>1,3</sup>; their inorganic complexes<sup>4</sup>; simple organic solutes<sup>5</sup>) were used to establish details of the reactivity of hydrogen atoms. The work was extended to enzymes (chymotrypsin<sup>6</sup>, trypsin<sup>7</sup>, ribonuclease<sup>8</sup>) to elucidate the action on biologically interesting substrates.

In the work recorded here we investigated the action of atomic hydrogen on aqueous solutions of ferri-cytochrome c. On one hand, this enables us to compare the reactivity of atomic hydrogen with other substrates containing a simple inorganic ion, such as the ferric ion<sup>3</sup>. However, the present case involves a protein associated with the complexed iron ion. On the other hand, the reactions of cytochrome c could be compared with the reactions of atomic hydrogen with various amino-acids<sup>9</sup> and with various proteins which do not contain an inorganic ion associated with the protein molecule<sup>4</sup>. In this way, the special features involved in the reactions of atomic hydrogen with cytochrome c could be elucidated.

Experimental details of the treatment with hydrogen-atoms were described previously<sup>1,3</sup>. The cytochrome c used was prepared by the method of Margolias<sup>10</sup> and only fraction I was used. Dose rates were determined using the ferri-cyanide method for the determination of the atomic hydrogen yield<sup>11,12</sup>.

All dose-rates in the work described here were  $2 \times 10^{-4}$  mole l.<sup>-1</sup> sec<sup>-1</sup>. 25 ml. of solution was used in the reaction vessel for each experiment. Control experiments were carried out, passing hydrogen gas only without discharge in order to ascertain the effect of bubbling alone on the stability of cytochrome c. No changes were observed due to bubbling only. In the actual experiments after passing hydrogen gas without discharge in order to clear the solution of oxygen, the discharge was lit and the atomic

Fig. 1. Absorption spectrum of  $3 \times 10^{-4}$  M ferri-cytochrome-c solutions at pH 7, after hydrogen atom treatment for:  $\Delta$ —0;  $\Delta$ — $\cdot$ — $\cdot$ —20;  $\Delta$ — $\cdot$ — $\cdot$ —60;  $\Delta$ — $\cdot$ — $\cdot$ —1,800 sec. Spectra taken under  $H_2$  atmosphere

hydrogen passed for the specified times. After treatment, samples could be withdrawn into a spectrophotometric cell under hydrogen pressure without air being admitted. The reproducibility of our results was of the order of  $\pm 10$  per cent for this series of experiments. The time of hydrogen atom passage was varied between 10 sec and 30 min through solutions containing 0.85 to  $3 \times 10^{-3}$  M of cytochrome c at pH 7 (maintained by 0.05 M phosphate buffer). The spectra obtained showed that at low doses only such spectroscopic changes occurred as were consistent with a simple reduction of ferri-cytochrome c. The ferri-cytochrome c formed in solutions treated up to this stage remained non-autoxidizable. When hydrogen atoms were continued to be passed into solutions in which ferri-cytochrome c was already reduced to ferro-cytochrome c, further far-reaching changes in the absorption spectrum were observed (Fig. 1), including the disappearance of the maximum at 315 mμ and a very considerable decrease of the optical density at 415, 520 and 550 mμ. The ferro-cytochrome c is now autoxidizable. When hydrogen atoms are continued to be passed, for example, for 90 min, further bonds are opened and free iron may be detected. The dependence of the secondary processes on the initial concentration of ferri-cytochrome c showed that the secondary processes occur only when ferri-cytochrome c is no longer present. So long as the ferri form is present, hydrogen atoms react preferentially with it. From the initial rates of the reaction (assuming that initially atomic hydrogen is used up for the reduction of ferri- to ferro-cytochrome c only) the rate constant of the reaction between atomic hydrogen and ferri-cytochrome c was calculated according to the procedure of Navon and Stein<sup>13</sup>. The value of  $k = 2 \times 10^9$  l. mole<sup>-1</sup> sec<sup>-1</sup>. In radiation chemical experiments, a value of the order of  $1 \times 10^9$  l. mole<sup>-1</sup> sec<sup>-1</sup> was obtained<sup>14</sup>. In Table 1, the rate constant now obtained is compared with the rate constants of other ferric complexes obtained with atomic hydrogen using the same experimental technique<sup>15</sup>. It will be seen that the rate constant of the reaction of atomic hydrogen with ferri-cytochrome c is similar to that of the fastest reactions of ferric ion complexes and is among the fastest measured for hydrogen atom reactions with various substrates<sup>15</sup>. The presence of protein thus

pH	7.0	6.0	5.0	2.5
$k/k_{\text{H}}$	1	0.66	0.58	0.14

does not slow down the reaction. The value now obtained may also be compared with the rate constant of ferri-cytochrome c with solvated electrons,  $e_{\text{aq}}^-$ , for which the same value as for the reaction<sup>6</sup> of ferri-cyanide ion with  $e_{\text{aq}}^-$ ,  $k = 3 \times 10^9$  l. mole<sup>-1</sup> sec<sup>-1</sup>, was found<sup>7</sup>. It will be seen that for ferri-cyanide and for ferri-cytochrome c, the rates of reduction with hydrogen atoms and with solvated electrons are very similar.

The dependence of the rate constant of the reaction of atomic hydrogen with ferri-cytochrome c on changes in the pH is shown in Table 2. The rate constant decreases on going from pH 7 to pH 2.5. The oxidation reduction potential increases and thus  $\Delta G$  of this reaction becomes more negative on going from pH 7 to pH 2.5 (Fig. 2). Therefore, the usual correlation between  $\Delta G$  of the reaction and the rate constant is not observed. For the reaction of ferri-cyanide with ferro-cytochrome c and ferro-haemoglobin respectively, Sutin and Christman<sup>8</sup> pointed out the lack of correlation between  $\Delta G$  and the rate constants. In our case, such behaviour may be attributed to configurational changes which have to take place during the reaction. In the present case, it is known that a pH dependent change in the configuration of the protein in its reduced form is observed at about pH 2.5. The 'crevice' in the amino-acid structure leading to the haem is open in both the ferri and the ferro form above pH 2.5, but is closed in the ferro form at and below pH 2.5. This configurational change, which is necessary in order to carry out the reduction process as pH 2.5 is approached, may slow down the reaction velocity.

It is interesting to compare the behaviour of ferri-cytochrome c with other proteins. It was found that enzyme proteins, for example trypsin and chymotrypsin which do not contain a metal prosthetic group but contain S—S linkages, are inactivated by reactions with atomic hydrogen which results in the opening of S—S bonds<sup>9,10</sup>.

Fig. 2. Dependence of  $E^\circ$  on the pH for aqueous solutions of fraction I of cytochrome c. Points ▲ determined by potentiometric, ○ by spectrophotometric, measurements. For details see N. Frohwirth, Ph.D. thesis, Jerusalem (1962).

Similar observations were made in the case of ribonuclease<sup>11</sup>. The rate constant of the reaction of hydrogen atoms with S—S links in trypsin is similar to that of hydrogen with ferri-cytochrome c. Cystine reacts with hydrogen atoms with a similar rate constant<sup>12</sup>. Unlike hydrolytic enzymes, cytochrome c does not contain any disulphide linkages, only thioether ones<sup>13</sup>. Its tertiary structure is probably maintained through links formed in hydrophobic areas within the protein structure.

It appears that were S—S links present near the active groups of cytochrome c, an oxidation reduction enzyme, they might have competed, as easily reducible groups, with the proper functioning of the enzyme. This work with hydrogen atoms indicates that the absence of S—S bonds in cytochrome c and the necessity to maintain protein structure by means other than in hydrolytic enzymes may be necessitated by such functional considerations.

### Magnetic Resonance Investigation of the Raney Nickel Catalyst

PREVIOUSLY<sup>1,2</sup>, one of us reported that the Raney nickel catalyst lost its activity through thermal treatment and that this might reasonably be related to the elimination of the crystal distortion in this catalyst. The structural change in the Raney-nickel catalyst by thermal treatment with the electron spin resonance technique has now been investigated.

Two samples of the catalyst, sample A being active in the hydrogenation reaction and B less active, were prepared by developing a nickel-aluminium alloy, the nickel content of which was 49 per cent, by the usual method<sup>3</sup>, then treating them at 70° and 300° C, respectively, in a vacuum (0.001 mm mercury) for 2 h and sealing them in a quartz tube with a 1-mm inner diameter.

The specific magnetization which was obtained at room temperature by the Faraday-type magnetic balance with an applied field of 3,000 oersteds was 0.22 and 0.51 for samples A and B, respectively. These values of the specific magnetization are expressed as  $\sigma/\sigma_0$ , where  $\sigma$  is the specific magnetization of the sample, and  $\sigma_0$  is that of nickel metal.

The increase in the magnetization on heating at 300° C may be caused by the evolution of hydrogen in the catalyst<sup>4</sup>.

The resonance spectra of the samples were taken at room temperature with a modulation field of 100 kc/s and

Fig. 1. A, Electron spin resonance signal from sample 4. The  $g$ -factor is 2.09; B, from sample B. The  $g$ -factor is 2.22

a microwave frequency of 9,403 mc/s on Nippon Denshi 3BX type electron spin resonance spectrometer. These spectra are shown in Fig. 1 A and B.

It is seen from these spectra that the signal of sample A is asymmetrical and broad while that of B, the activity of which was reduced by treating at 300° C, is symmetrical. These phenomena observed in sample A are accounted for by anisotropy of the  $g$ -factor in its microcrystals.

The measured  $g$ -factor on sample B, 2.22, agrees with that obtained for nickel by other workers<sup>1</sup>.

The results presented here suggest that the lattice imperfections in the active catalyst are diminished by the thermal treatment. The decline of the catalytic activity may be closely related to the diminution of the lattice imperfections in microcrystals of Raney nickel catalyst.

We wish to thank Mr. T. Ohki, Mr. Y. Orito and Mr. T. Yoshida for their assistance.

### Presence of 1,3,6,7-Tetrahydroxyxanthone in Maclurin from *Chlorophora tinctoria* (L) Gaud. (*Morus tinctoria* L) (Moraceae)

DURING the course of our work on Guttiferae we required maclurin (I). Examination of commercial maclurin extracted from *Morus tinctoria*\* (Moraceae) (we thank the Aldrich Chemical Co. for disclosing their source of maclurin) showed a small amount of impurity which was identified as 1,3,6,7-tetrahydroxyxanthone (IIa) by comparison with an authentic sample using paper chromatography (Whatman No. 1; 60 per cent aqueous acetic acid;  $R_F$  0.70). 1,3,5,6-Tetrahydroxyxanthone (IIIa) has a similar  $R_F$  value but a different colour under ultra-violet light, and the structure of the

impurity was therefore confirmed by methylation with dimethyl sulphate. The resulting 1,3,6,7-tetramethoxyxanthone (IIb) was identified by thin-layer chromatography (silica gel by Stahl; benzene-chloroform, 3:7;  $R_F$  0.35) because under these conditions the isomeric 1,3,5,6-tetramethoxyxanthone (IIIb) has a higher  $R_F$  (0.42). Authentic xanthones were prepared by unambiguous synthesis<sup>1</sup>.

Although 1,3,6,7-tetrahydroxyxanthone (IIa) has not been previously detected in *Morus tinctoria* its presence is not surprising now that we have shown that its formation from maclurin (I) occurs *in vitro* by phenol oxidative coupling. Thus irradiation of a 1 per cent boiling ethanolic solution of maclurin with ultra-violet light (Hanovia medium pressure lamp) in a stream of oxygen for 30 h gave 1,3,6,7-tetrahydroxyxanthone (45 per cent) (IIa) which was isolated after methylation with diazomethane as the insoluble sodium salt of 1-hydroxy-3,6,7-trimethoxyxanthone (IIc) (ref. 2). 1,3,5,6-Tetrahydroxyxanthone (IIIa), which can also be theoretically formed from maclurin, was not detected under these conditions although macluraxanthone (IV) with this oxygen substitution pattern has been obtained from *Maclura pomifera*<sup>3</sup>.

At this stage we cannot preclude the possibility that 1,3,6,7-tetrahydroxyxanthone may have been formed from maclurin during extraction and isolation from *Morus tinctoria*.

### A Chemical Model for Electrolytic Oxidation of Iodate

DURING an investigation of the electrolytic production of periodate from iodate, the oxidation of iodate was expressed mathematically as a chemical reaction in which gaseous oxygen formation competed with the desired

reaction for the available supply of a common precursor material<sup>1</sup>. In writing the equations, liberties, which could be mathematically rationalized, were taken with the classical forms of the rate equation, but these liberties resulted in equations that could only approximate real counterparts. In particular, it was stated that "sometimes, in the early stages of the oxidation, the reaction proceeds at a very slow rate. This is attributed to an initial lack of catalytic activity at the surface . . .". The question has always remained, whether or not the classical equations, which were modified mainly to facilitate solution, would not better express the total behaviour of an operating cell. Another intriguing question has been the identity and quantitative behaviour of the precursor material. Now the set of classical equations has been solved on an analogue computer and insight has been gained into the electrode processes which could occur.

The set of classical equations investigated was as follows:

$$\begin{aligned} y' &= K_1 z (1 - y) \\ x' &= K_2 x^2 \\ x' + y' + z' &= \frac{i}{2F} \end{aligned} \quad (1)$$

where  $\frac{i}{2F}$  is the rate of atomic oxygen production,  $x$  is the amount of gaseous oxygen,  $y$  is the amount of periodate,  $z$  is the amount of the oxygen precursor to both  $x$  and  $y$ ,  $K_1$  and  $K_2$  are the specific reaction rates for periodate and oxygen, respectively. Primes refer to the time rates for the variables.

This set argues that the oxygen production rate is bimolecular, as it would be if free radical oxygen were the precursor. Several comparisons for data fit were made between this assumption and the previous assumption<sup>1</sup> that the oxygen rate follows a monomolecular law, which could occur if the oxygen precursor were an oxide of lead so that a reaction such as:

could occur. In such a case, the periodate oxidation could still be monomolecular with respect to iodate by a reaction such as:

It is realized that the true reactions may be much more complicated and involve several possible chemical entities, such as  $\text{H}_2\text{O}_2$ ,  $\text{Pb}(\text{IO}_3)_2$ , and  $\text{Pb}(\text{IO}_4)_2$ , at the anode interface. At the present state of technology in measuring the instantaneous compounds of lead, knowledge about them must be primarily non-specific and arrived at by inference.

Unfortunately, the computer data gave no information regarding molecularity. The two curves were so similar in shape that either could be fitted to the chemical data within experimental error. The only effect was to change the ratio  $K_1/K_2$ , as one might expect from examining the equations. Since the precise reactions are not known, the possibility of determining the absolute value of either of the specific rates seems remote.

A fault with the simplification previously made to derive the approximate model was the omission of  $z'$  from the material balance equation. If  $z'$  is truly zero, then  $z$  could be a constant and the oxygen production equation would be unnecessary. The solution then degenerates into a simple first-order equation in  $y$ .

Under certain conditions and over a restricted range the computer investigation disclosed that  $z$  is approximately linear in time and that then the shapes of the approximate and classic curves are the same within experimental error for the chemical data.

Comparison of the classical and approximate models is shown in Fig. 1.

Where the chemical data showed an appreciable 'induction' period, the classical model fitted the total range, whereas the approximate model fitted only the later portion. In some cases, however, these data did not show an

Fig. 1. Difference between classical (a) and approximate (b) models in early stages of oxidation

induction period. An attempt was made to force the classical equation toward the approximation by making  $K_2$  large relative to  $i/2F$ . The curve shape did not yield readily to this attempt.

The second attempt to explain the lack of induction in some data was to assume a third parameter in the classical equation. By making the initial value of  $z$  equal to about half the final value, the induction period was lost. This adjustment gave good fits for a wide range of data, from an inefficient cell to a most efficient one, and for those either showing or not showing an induction period. Some typical curves of  $y$  and  $z$  are given in Figs. 2 and 3. The parameters for several runs are given in Table 1, where the 'efficiency factor'  $K_1/K_2$  is compared with the approximate values.

Table 1. COMPARISON OF EFFICIENCY FACTORS IN APPROXIMATE AND CLASSICAL MODELS

Cell	Current (amp)	$i/2F$ % Theoretical conversion/h	Efficiency factor, $K_1/K_2$ Approximate	Classical ( $K_1 = i/2F$ )
A	30	24.7	4.3	5.3
A	65	25.7	3.1	3.1
A	100	41.1	2.6	3.1
B	65	25.7	5.8	7.0
O*	65	25.7	2.8	2.3

\* Anode area 3.7 times as great; flow rate, lower.

The value for  $K_2$  did not alter the early shape of the curve appreciably. To prevent the value of  $z$  from exceeding the computer voltage tolerance,  $K_2$  was taken to be equal to  $i/2F$ . At infinite time,  $x'$  approaches  $i/2F$ .

Fig. 2. Classical curves with an appreciable induction period

Fig. 8. Classical curves without an induction period

Thus,  $z$  is always equal to or less than unity, which was scaled to be the maximum computer voltage.

In the equations,  $K_s$  turns out to be equal to  $1/(s_{\max})^2 \cdot i/2F$ . Consequently  $K_s$  is not so much a specific rate as a measure of the oxide-holding capacity of the anode relative to the amount of current applied. It is therefore somewhat dependent on current density, as an analysis of the results in Table 1 shows.

These investigations demonstrate that the approximate model has good empirical justification over most of the data range and that the classical model, as formulated, has some flaws. Considering the greater complexity that would be involved in using the classical model, the approximate one is suggested for engineering calculations.

## BIPHYSICS

### Advantages resulting from the Addition of a Versatile Multichannel Analyser to an Electron Spin Resonance Spectrometer

A MULTICHANNEL analyser has been added to our electron spin resonance spectrometer to be used as a computer of average transients<sup>1</sup>. This communication describes the elements of the system and some of the important advantages that a versatile analyser can provide. Briefly, the principle of the computer of average transients is that successive sweeps of a spectrum are added in a multichannel memory system, so that the signal, coherent with each sweep, adds linearly in the memory, while the noise, which is random, adds in quadrature. This results in an improvement of signal-to-noise ratio after  $N$  sweeps of  $\sqrt{N}$ .

The analyser system used here consists of a clock pulse generator, 400 channel analyser and a magnetic tape calculator (Intertechnique types HC40, SA40B and RG28 respectively) and a high-gain d.c. amplifier (Rochaz type A1388). Modifications were carried out by the manufacturers at our request to suit our spectrometer which include the high-gain d.c. amplifier placed between the spectrometer and the analyser, and a biasing circuit placed before the analogue-to-digital converter, so that any negative voltages that might arise from the signal can be offset. The manufacturers themselves have introduced a useful variant of the standard analyser for

computer of average transients applications by using a pulse train of 10 times the frequency of the address advance, which is used to open the 'gate' of the analogue-to-digital converter ten times in each channel, thus sampling the signal ten times. In this manner  $N$  sweeps of the spectrum represent  $10 \times N$  samples of this spectrum. The signal-to-noise ratio then can be considered to be improved by a factor of  $\sqrt{10N}$ .

Since the analogue-to-digital converter in its most sensitive setting quantizes voltages in increments of 10 mV, and because our spectrometer<sup>1,2</sup> was constructed to drive a 10-mV recorder, the high-gain d.c. amplifier was necessary in order to see signals which are less than 10 mV in amplitude. This amplifier has a variable gain in steps of times 20, 50, 100, 200, 500, 1,000.

The sweep of the multichannel memory is synchronized with the sweep of the magnetic field which provides the electron spin resonance spectrum, by a 'start' pulse circuit which is triggered when the voltage across the magnetic field sweep coils reaches a pre-set value. It is planned to modify this to provide a steady magnetic field value for each channel, by driving the magnet sweep coils from a staircase wave-form obtained from analyser channel address register, via a suitable current amplifier.

We have found that, with our system, the optimum results are obtained with a sweep of 100 gauss in 4-8 sec. We have so far limited operations to 100 sweeps, giving an improvement in signal-to-noise ratio of approximately 30. At the moment this is quite adequate. Such a sweep time allows one also to retain a small time constant in the spectrometer, thus eliminating some noise before the analyser. It was found that our sweep generator (or 'start' pulse circuit) could be triggered by the 50 c/s mains frequency ripple, and if the dwell time in any channel is less than 10 msec, the half-period of the mains, an undesirable addition of 50 c/s pick-up occurs with each sweep. This can be eliminated by careful choice of channel frequency or total number of channels used.

The improvement of  $\sqrt{10N}$  is not considered to be one which can be increased indefinitely. It is limited by two factors, the frequency stability and the magnetic field stability of the electron spin resonance system. If these are poor then the lines in a spectrum are not quite coherent for each sweep and consequently they will be averaged out. For wide lines these instabilities are relatively unimportant. For a line 20 gauss wide, however, using 4-sec sweeps, if one assumes bad drifts of field and frequency of, say, 1.0 gauss/h and 1.0 Mc/s/h, and that the maximum tolerable shift of the line is 0.2 of its width, then we calculate that the maximum number of sweeps possible is  $2.7 \times 10^3$ , which limits the signal-to-noise improvement to 164.

In addition to the improvement in sensitivity, the other advantages found with this system are the operations which are possible using the magnetic tape calculator. First, by storing a 'background' spectrum, for example the spectrum from an empty sample cell, any contribution resulting from this can be subtracted later from the spectrum of interest taken with a sample inside the cell.

Secondly, the sample spectrum when recorded on tape can be integrated and the integral recorded, which can, in turn, be integrated again. In this way first derivative spectra can be integrated twice to provide information about the number of spins contained in the sample. There are more steps involved in this operation, however, which is conducted in the following manner:

(1) A straight line,  $f_1 = a$ , is obtained on the analyser by storing the same number of counts in each channel, a facility which is provided on the analyser. This straight line is recorded on tape.

(2) The straight line is played back into the analyser in the integration mode, where the contents of each channel represents the total of all channels before it. The line  $f_2 = ax + b$  is thus obtained and stored on tape.

(3) A background spectrum is taken and stored on tape (Fig. 1a).

(4) Now the sample spectrum is taken and the background is subtracted from it, leaving in the memory a curve  $f_s = \frac{d\chi''}{dx} + c$ , in which  $x$  is proportional to  $H$  and  $c$

is a constant. This is recorded on tape (Fig. 1b).

(5) The curve  $f_s$  is now integrated to give  $\int f_s dx = \chi'' + cx + d$ . From this is subtracted  $f_s$  multiplied by a suitable constant to leave  $f_a = \chi'' + e$ . This represents the true absorption curve superimposed on a base-line of height  $e$  (Fig. 1c).

(6) Again this is recorded and integrated to give  $\int f_a dx = \int \chi'' dx + ex + f$ ;  $f_a$  is subtracted again multiplied by a suitable constant to leave  $f_b = \int \chi'' dx + g$ . Now  $\int \chi'' dx$  is proportional to the number of spins and  $g$  is merely a constant (Fig. 1d).

The process is calibrated using a sample containing a known number of spins. Although this appears to be a long process, in fact each recording or playing back operation takes only 4 sec. More time is spent in obtaining the spectra. The errors involved in the usual method of manual integrations of pen recording traces have been found to be as high as 10 per cent; with this procedure described here they are reduced to about 1 per cent.

Fig. 1

One further point about the integration is that the integration procedure tends to introduce a further apparent reduction of noise, but one which depends on the channel number. This arises from the fact that, in channel 400, the addition of the contents of all 399 channels before it results in the noise ratio of channel 400 to channel 1 being improved by  $\sqrt{400}$ , while at channel 10 an improvement of only  $\sqrt{10}$  results.

In addition to the integration facility one can also differentiate a spectrum by subtraction of the same spectra shifted relative to each other by a number of channels small relative to the line width. As is well known this is particularly useful for the measurement of  $g$  values since the second derivative will show an antinode at the value of  $g$ . The analyser is provided with markers so that the exact channel number of an antinode can be determined. In this way, by calibration against a standard sample, an accuracy of 1 in 10,000 in  $g$  can be obtained, the accuracy depending mainly on magnet stability.

We thank the Medical Research Council for the grant to purchase the multichannel analyser, the Science Research Council for supporting this work, and D. Ritchie for his help.

## BIOCHEMISTRY

### Changes in Concentration of Polyamines in the Developing Mouse Brain

SPERMIDINE and spermine have recently attracted much interest because of their physical affinity to nucleic acid<sup>1-3</sup> and stimulating effect on cell proliferation<sup>4-6</sup>. These amines occur in high concentrations in actively proliferating tissues such as human semen<sup>7</sup>, growing chick embryo<sup>8</sup>, and germinating plant seeds<sup>9</sup>. These tissues contain a high concentration of deoxyribonucleic acid (DNA). Rama<sup>8</sup>

has recently found high concentrations of polyamines in the chick embryo which later decreased during incubation. We<sup>10</sup> have described the localization of spermine in the cell nucleus using nucleated and non-nucleated blood cells. These findings suggest the importance of polyamines in the growth process of plant and animal tissues.

Among the animal tissues, it is of advantage to use brain tissues for the study of a substance during growth since each component of the tissue, such as cell body, neuronal fibre, and myelin sheath, grows in different phases of the development and since the concentrations of substance which associate with each cellular component change in parallel with their cytological features.

In the present study the concentrations of spermidine and spermine were determined in brain and, for comparison, in liver, at various stages of development in the mouse (*ddO* strain) according to the method reported previously<sup>11</sup>. Although this method was devised originally for the determination of the amines in nervous tissue, examination of the specificity and recovery rate proved the method to be applicable to the determination of the amines in the mouse liver. The concentration of DNA in the brain was determined in parallel according to Schmidt

and Thanhauser<sup>12</sup>.

A high concentration of spermidine found in the foetal mouse brain decreased during the first 28 days after birth. The concentration of spermine in the brain remained at a high level until the twenty-first day after birth and fell during the following 7 days (Fig. 1). It is known from histological investigations of the rat brain that during the 20 days after birth it is characterized by cell division and the increase in size of individual cells and especially by the extension of axons and dendritic connexions<sup>13</sup>. In general, the cause of development of the mouse brain has been shown to be almost the same as that of the rat<sup>14,15</sup>. Later, the concentration of both amines remained at lower constant levels until the adult stage was reached (Fig. 1).

As shown by early experiments in other species<sup>16-18</sup>, the concentration of DNA in the mouse brain was highest in the pre-natal stage, dropped abruptly during the first 7 days after birth, and decreased slowly from then to the adult level (Fig. 2). These changes are similar to those of

Fig. 1. Changes in the concentrations of spermidine and spermine of mouse brain during maturation. ○, The concentration of spermidine; ●, the concentration of spermine. Each spot is the average of three experiments. Vertical lines indicate standard deviations. Spots without vertical line have S.D. < 2.0 µg/g.

the polyamines, but changes in DNA concentration preceded those in the concentration of polyamines.

In the liver, of which the cells are known to reach maturation at the early pre-natal period and to continue relatively constant proliferation thereafter, no change in the concentration of the amines was observed during the early period after birth, in contrast to the marked changes in the brain. Gradual and slight decrease of spermidine and increase of spermine were observed (Fig. 3).

In summary, the concentration of polyamines in the mouse brain was shown to be higher in the pre-natal and early post-natal life than in adult. This trend was more apparent if the concentrations were calculated on a dry

Fig. 2. Changes in the concentration of DNA and in the proportion of dry matter of mouse brain at different ages. ○, concentration of DNA as microgram DNA phosphorus per g of wet tissue; ●, proportion of dry matter as percentage of wet tissue.

Fig. 3. Changes in the concentrations of spermidine and spermine of mouse liver during maturation. ○, The concentration of spermidine; ●, the concentration of spermine. weight basis, since the water content in the brain decreases during development (Fig. 2). A high concentration of spermidine and spermine of the brain during the proliferation stage followed by a drop in concentration after this stage is considered to provide further evidence of their biological function in cell growth. Most substances and enzyme activities in the brain increase during development, in contrast to polyamines and DNA.

## Isolation and Identification of 2-Aminoethylphosphonic Acid from Bovine Brain

In the course of isolating unidentified amino-compounds from bovine brain<sup>1-3</sup>, a substance was isolated from the neutral amino-acid fraction of the trichloroacetic acid of the brain, and was identified as 2-aminoethylphosphonic acid from the results of elementary analysis, infra-red spectrography and chromatography. The occurrence of 2-aminoethylphosphonic acid in protozoa<sup>4,5</sup> and in the sea anemone<sup>6</sup> has been reported both in free and combined form; but its presence in the higher animals has not been reported in either form until now.

Seventy-five bovine brains, weighing 28.5 kg, were extracted with trichloroacetic acid and desalted<sup>1</sup>. The pooled and concentrated extract (800 ml.) was separated into the acidic, neutral, and basic fraction by the methods described for the isolation of  $\beta$ -aminoisobutyric acid from urine<sup>1</sup>. The neutral fraction was concentrated to about 800 ml. *in vacuo*, filtered, and was applied to a 6 cm  $\times$  7 cm column of 'Amberlite IR-120',  $\times$  8 (100-200 mesh, pyridine form). The resin was washed with 800 ml. of water and the substances were eluted with 1 N pyridine. The first 800 ml. of the eluate was discarded, and the following 2,300 ml. was collected, concentrated to 150 ml. and filtered. The filtrate was acidified to pH 2.0 by the addition of formic acid and the solution was charged on to a 5.3 cm  $\times$  137 cm column of 'Amberlite OG-120',  $\times$  8 (200-400 mesh), previously buffered with a mixture of pyridine-formic acid-water (1:9:190, v/v), pH 2. The same buffer was used for elution, and the emergence of compounds was followed by examining aliquots of the eluate by paper chromatography. Two unidentified ninhydrin-positive substances emerged in the eluate between 1,760 ml. and 2,880 ml. This portion of the eluate was concentrated to a small volume, and was further purified by chromatography on a 2 cm  $\times$  30 cm

Table 1. PAPER CHROMATOGRAPHIC AND ELECTROPHORETIC PROPERTIES OF 2-AMINOETHYLPHOSPHONIC ACID AND THE RELATED COMPOUNDS

	R <sub>F</sub> values with solvent systems				Migration distances (cm) toward anode with buffers	
	Pyridine-acetone-3 N ammonia (60:30:25, v/v)	Isopropanol-formic acid-water (8:1:1, v/v)	n-Butanol-acetic acid-water (4:1:1, v/v)	Phenol-water (8:2, v/v)	Pyridine-acetic acid-water (1:10:180, v/v) pH 5.4 100 V/cm, 1 h	Formic acid-acetic acid-water (3:8:56, v/v) pH 1.8 40 V/cm, 30 min
Isolated compound	0.03	0.23	0.24	0.35	1.1	4.1
2-Aminoethylphosphonic acid	0.03	0.23	0.24	0.35	1.1	4.1
1-Aminoethylphosphonic acid	0.02	0.26	0.30	0.34	0.7	3.6
2-Aminoethylphosphate	0.02	0.17	0.22	0.35	0.8	3.9

column of 'Dowex 1', × 10 (200–400 mesh), equilibrated with a mixture of 2,4-lutidine-acetic acid-water (10.7:1.5:488, v/v), pH 7.0. Substances were eluted from the column by 140 ml. of the same buffer followed by a mixture of 2,4-lutidine-acetic acid-water (10.7:0.3:489, v/v), pH 7.7. One of the unidentified substances emerged in the eluate between 51 ml. and 171 ml. The eluate was evaporated to dryness *in vacuo*. The residue was crystallized from 1 ml. of water, 1 ml. of ethanol and 0.5 ml. of acetone to obtain 18 mg of needles, m.p. 255° C (decomp.), raised to 270° C (decomp.) on recrystallization. Elementary analysis gave: C, 19.41; H, 6.57; N, 11.12; C<sub>5</sub>H<sub>10</sub>NPO<sub>3</sub> requires C, 19.21; H, 6.44; N, 11.20. Phosphorus was detected by wet ashing.

On hydrolysis of a portion of the crystal with 6 N hydrochloric acid at 105° C for 15 h, neither change in the chromatographic behaviour of this substance nor the liberation of inorganic phosphate was observed. Stability of the compound to acid hydrolysis suggested the presence of a covalent linkage between C and P. In paper chromatography<sup>1,2</sup> and electrophoresis<sup>1,2</sup> this substance migrated to a position close to that of 2-aminoethyl phosphate. These data were compatible with those of either 1-aminoethylphosphonic acid or 2-aminoethylphosphonic acid. On comparison with synthetic compounds the isolated substance behaved like the latter in paper chromatography with four different solvent systems and in paper electrophoresis under two different conditions, but on neither occasion like the former (Table 1). The infra-red spectrum of the isolated substance was identical with that of the β-crystal<sup>6</sup> of synthetic 2-aminoethylphosphonic acid.

2-Aminoethylphosphonic acid has a C-P linkage, the occurrence of which has not been reported in the body of vertebrates. Little information about the enzymatic formation and degradation of the linkage is available. Rosenberg<sup>3</sup> showed that there was an exchange of 2-aminoethylphosphonic acid between the protozoa, *Tetrahymena pyriformis*, and the surrounding medium. Horiguchi and Kandatsu<sup>12</sup> found recently that oral or intraperitoneal administration of radioactive 2-aminoethylphosphonic acid to rat resulted in the accumulation of this compound in the liver, kidney, spleen, and many other tissues. As *Tetrahymena* exists in the bovine rumen symbiotically, there is a possibility that 2-aminoethylphosphonic acid isolated from bovine brains is derived from the protozoa in the rumen. Considering the recovery of the substance during isolation, the concentration of free 2-aminoethylphosphonic acid in bovine brain is calculated to be about 2 μg/g wet tissue.

The combined forms of 2-aminoethylphosphonic acid with glycerol<sup>4</sup> and with ceramide<sup>11</sup> have been demonstrated in protozoa and in sea anemones, respectively. As brain is abundant in phospholipid, this tissue was expected to contain a combined form of the phosphonic acid. In our preliminary experiments, however, the concentration of 2-aminoethylphosphonic acid in the hydrolysate of the lipid fraction (chloroform-methanol soluble component) of bovine brain was found to be less than 1 μg/g wet tissue, if present.

We thank Mr. M. Horiguchi and Mr. M. Kandatsu, Department of Agriculture, Tokyo University, for supply-

ing synthesized crystals of 2-aminoethylphosphonic acid and its 1-amino isomer.

Bioassay of Pituitary Gonadotropins

DURING the course of purification of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from horse pituitary glands<sup>1</sup> the following method was used to determine the degree of separation of FSH and LH at two purification steps. A pH-5 soluble gonadotropic fraction and a purified FSH preparation from the third zone-electrophoresis were compared as to their effect on the increase in the weight of ovaries as a measure of FSH and ventral prostate as a measure of LH in hypophysectomized rats (Holtzman Co., Madison, Wisconsin). A dose-response relationship was developed between the ovarian weights obtained by different doses of the pH-5 soluble fraction. The doses of the FSH fraction from the third zone-electrophoresis were selected so as to induce essentially the same ovarian response as was obtained with various doses of the pH-5 soluble fraction. The average weights of the ventral prostate produced by these doses were used as a measure of the LH content of the two fractions. The results are presented in Fig. 1 and Table 1.

The slope of the dose-response relationship for LH decreased significantly<sup>2</sup> from 0.13 for the pH-5 soluble gonadotropic fraction to 0.07 for the FSH from the third zone-electrophoresis while the slope for the dose-response relationship for FSH of the same preparations increased from 0.43 to 0.63. The slope ratio of FSH to LH for pH-5 soluble gonadotropins increased from 3:1 to 9:1 for FSH preparation after the third zone-electrophoresis. These observations suggest that significant separation of FSH and LH was achieved and further suggest that FSH and LH are separable and different entities in the horse pituitary gland. It will be of interest to learn whether

Table 1. HORMONAL ACTIVITY OF HORSE PITUITARY GONADOTROPIC FRACTIONS IN HYPOPHYSECTOMIZED RATS

Preparation	Protein mg/g fresh tissue	Slope FSH	(b) LH	Slope ratio FSH: LH
pH 5 Soluble gonadotropin	11.6	0.43	0.13	3:1
Third zone electrophoresis FSH	0.44	0.63	0.07	9:1

Fig. 1. Graphs showing results of the bioassay in hypophysectomized rats of the pH 5 soluble fraction of horse pituitary glands and the FSH preparation obtained from this fraction after the third zone electrophoresis.

this observation can be used in following the separation of two substances with overlapping biological activity.

## Effect of Human Growth Hormone on Insulin Basic Protein Complex

It is generally agreed that there are two forms of insulin circulating in human blood plasma: (i) the immunologically inactive form bound to a basic protein<sup>1-3</sup>; (ii) the immunologically active free form<sup>4</sup>.

In our *in vitro* studies of the binding reactions between <sup>125</sup>I-bovine insulin (Radiochemical Centre, Amersham) and a commercial insulin antibody preparation (Burroughs Wellcome) the effect of other hormones on these binding reactions was observed.

The method used to indicate <sup>125</sup>I-insulin-antibody binding was similar to that described by Meade and

Fig. 1. Effect of added HGH on <sup>125</sup>I-insulin-antibody binding. O, Percentage bound in serum; ●, percentage bound in 3.95 per cent human serum albumin.

Kiltgaard<sup>5,6</sup>, who used an anion exchange resin to separate the free <sup>125</sup>I-insulin from the insulin bound to that antibody, this giving a good index of the bound-to-free ratio of <sup>125</sup>I-insulin.

It was found, on adding human growth hormone (HGH) (U.S. National Institutes of Health) to insulin antibody in the presence of human fasting serum, that the proportion of <sup>125</sup>I-insulin bound to antibody decreased, with increase in the amount of HGH added. When repeated with antibody in 3.95 per cent human serum albumin, no change occurred (Fig. 1).

It was postulated that HGH displaced endogenous insulin from the insulin-basic protein complex, and made it available for antibody binding. This theory was supported when it was found that <sup>125</sup>I-HGH<sup>7</sup> could be partly extracted from serum by the cation exchange resin 'Dowex 50' (Na cycle) but not from 3.95 per cent albumin. This indicated that some HGH is bound to a basic protein in human blood plasma.

## Phenolic and Indole Amines in the Urine of Schizophrenics

The hypothesis that schizophrenia may be caused by a metabolic abnormality of phenolic or indolic amines has gained supporting experimental results by some research groups, but conflicting results by others. This confused state was reviewed by Kety<sup>1</sup>, and the contradictory results could be explained by various factors related to different environmental and physical conditions which are secondary to the psychosis. An attempt was made to examine in this laboratory the excretion of various phenolic and indole amines using the subjects under careful control of environmental factors.

Seven schizophrenic patients having 5-7 year courses of the disease and eight normal subjects who were on the same diet were selected. Routine clinical examinations revealed no physical abnormalities in both groups of subjects. Medications were withdrawn for more than a month before the collection of urine and both patients and controls were engaged in the same degree of physical work. Twenty-four hour urine specimens of schizophrenics were collected under strict supervision for 3 days, but collection of a full 24-h urine failed frequently because of pathological behaviour of the patients. Thirteen specimens of complete 24-h urine could be collected. Urine was collected on the second day from normal subjects. Urine was kept in a refrigerator during the 24-h collection and then kept at -20° C. Quantitation of amino nitrogen, urea, creatinine, creatine and uric acid of these specimens showed that there were no pathological changes in the amounts of these nitrogen compounds in the urine of both groups.

Paper chromatograms of phenolic amines were prepared according to the method of Kakimoto and Armstrong<sup>2</sup>. Diazotized *p*-nitroaniline was used for the detection of phenolic amines. Paper chromatograms of indole amines were prepared in the same manner as phenolic amines and rendered visible with the *p*-dimethylaminobenzaldehyde reagent. Compounds listed in Table 1 were detected

Table 1. PHENOLIC AND INDOLE AMINES AND THE FREQUENCY OF THEIR APPEARANCE IN URINE SPECIMENS OF SCHIZOPHRENICS AND NORMALS

Compounds	Frequency	
	Schizophrenics	Normals
No. of urine specimens examined	18	8
Normetanephrine	13	8
Metanephrine	13	8
p-Tyramine	11	8
m-Tyramine	13	8
Histamine	10	4
3-Methoxytyramine	7	0
p-Hydroxybenzylamine	2	0
p-Sympathol	8	2
Serotonin	13	8
Tryptamine	13	8

in the urine specimens from the normal subjects and patients. Frequency of the appearance of the spots on the paper chromatograms are shown in Table 1. Seven unidentified indole compounds which are not listed in Table 1 were found in several specimens of both groups, but these compounds were not specifically detected in one of the two groups. A trace amount of 3-methoxytyramine was found only in the urine of schizophrenics in this investigation. This difference can, however, not be taken as difference in the metabolism of catecholamines between the patients and normals, because this compound has also been detected in paper chromatograms of urine of normal subjects in a previous investigation<sup>3</sup>, and because this amine is a normal constituent of human urine as a conjugated form. Bufotenin has been claimed to be a constituent of the urine of schizophrenic patients<sup>4</sup>, but no detectable amount of bufotenin was found in the present investigation. Considering the sensitivity of the method used, the amount of bufotenin is less than 20 µg in 24-h urine, if present.

Phenolic acids and indole acids in the urine specimens were also examined by paper chromatography according to the methods of Armstrong *et al.*<sup>4,5</sup>, and no qualitative differences of various acids were observed between the two groups.

In our previous investigation the finding by Friedhoff *et al.*<sup>6</sup> that 3,4-dimethoxyphenylethylamine is found in the urine of schizophrenic patients but not in normal urine has not been supported<sup>7</sup>. In the investigation recorded here other phenolic and indole amines were examined in the urine of schizophrenic patients: no result was obtained which would support a hypothesis of abnormal metabolism of these amines in the disease.

## PHYSIOLOGY

### Catheptic Activity of the Gastrointestinal Tract, Liver, Spleen and Kidney of the Rat

As reviewed by Fruton<sup>1</sup>, cathepsins are intracellular proteinases with acid pH optima, ubiquitously found in animal tissues. In the mammal, highest concentrations of cathepsins are found in liver, kidney and spleen<sup>2-4</sup>. However, perfused rat liver was found to catabolize only 13–16 per cent of the total albumin broken down in the whole animal<sup>4</sup>.

The rapid turnover of the gastrointestinal tract is well documented. The finding of catheptic activity in rat intestinal mucosa of magnitude comparable to that of rat liver<sup>5</sup> prompted a comparison of catheptic activity in the various segments of the gastrointestinal tract with that of rat liver, spleen and kidney.

Male Sprague-Dawley rats (300–370 gm) were decapitated after a 24-h fast and the livers, kidneys and spleens were washed and homogenized in 0.25 M sucrose. The small intestine was divided into three equal parts; that next to the stomach was arbitrarily called the duodenum, next the jejunum and next the ileum. These segments, as well as the stomach, caecum, and colon, were homogenized in 0.25 M sucrose after careful washing. The proteolytic activity of the homogenates was determined in 0.1 M acetate buffer pH 3.7, with denatured haemoglobin (10 mg/ml) as substrate. Proteolytic activity was measured as free amino-acids expressed in terms of tyrosine equivalents. Proteolytic activity and protein concentrations of the tissues were measured by the colorimetric method of Miller<sup>7</sup>.

Results in Table 1 show the high catheptic activity and proteolytic capacity of the gastrointestinal tract. The figures in the last column give an approximation of the proteolytic capacity of the organs. A more accurate picture could be obtained only by taking into account the turnover rate of the various organs, a consideration which would probably magnify the catabolic capacity of the gastrointestinal tract. Friedberg *et al.*<sup>8</sup>, for example, showed that when <sup>35</sup>S methionine is given to fasted rats, the intestinal mucosa proteins show the highest specific activity of <sup>35</sup>S and also a rapid loss of activity.

Table 1. COMPARATIVE CATHEPTIC ACTIVITY OF THE GASTROINTESTINAL TRACT, LIVER, SPLEEN AND KIDNEY OF THE RAT

Tissue	Average wet wt./rat (g)	Specific activity	Calculated proteolytic
		nanomoles tyrosine released/min/mg protein	capacity haemoglobin (g) hydrolysed/rat/24 h
Stomach	1.60	62.5	10.3
Duodenum	3.68	15.8	4.06
Jejunum	3.66	6.8	7.62
Ileum	3.39	11.8	2.94
Caecum	1.12	7.3	1.36
Colon	2.11	11.5	2.63
Liver	9.53	5.07	17.8
Kidney	2.75	15.1	10.4
Spleen	.69	25	4.75

Values are the averages of 3 experiments, each including 16 rats. The high value for stomach may have been contributed to by pepsinogen activated by the low pH of incubation.

Our data indicate that in any quantitative study of overall catheptic activity or breakdown of plasma proteins, it would be advisable to include the different segments of the gastrointestinal tract.

This investigation was supported by U.S. Public Health Service research grant 5609 and U.S. Department of Agriculture project WM-33.

### Transauricular Perfusion of the Pituitary Gland in Rats and Mice

So far as we know, intrapituitary injections<sup>1-7</sup> or implants<sup>8-11</sup> have been performed only on adult rats<sup>1-3, 8-11</sup> or on bigger animals such as rabbits<sup>4, 7, 12-14</sup> or dogs<sup>15</sup>. For these experiments stereotaxic methods are usually adop-

Fig. 1. Apparatus for intrapituitary micro-injections. A, microsyringe with needle inserted; B, vinyl tube; C, connection between the vinyl tube and the needle for micro-injections; D, needle for micro-injections; E, outer sheath; F, middle sheath; G, tip

Fig. 2. Drawing of a skull of a 21-day-old rat, showing actual position and size of needle (in solid black) during the perfusion into the hypophysis (outlined area). The outer sheath of the needle rests against the petiotic capsule wall, the middle sheath fits into the hole made by the perforating needle and the point enters the pituitary

ted. In this communication a technique is described which renders it possible to perform injections or perfusions into the pituitary gland of both immature and adult rats and mice. To this purpose a needle has been devised which allows entrance to the hypophyseal tissue by the transauricular approach. Such a route had been already used to perform, with suitable instruments, both pituitary ablation<sup>10,11</sup> and transplantation<sup>12</sup>.

The equipment (Fig. 1) consists of a special needle connected through a vinyl tube to a hypodermic needle mounted on a microsyringe. The special needle is made of three stainless steel tubes of increased length (outer sheath, middle sheath and tip) coaxially fitted and soldered to a socket. These features will determine and maintain the proper position of the needle during the injection (Fig. 2). Another steel tube (outside diameter 1.1 mm) is soldered to the opposite side of the socket for the junction with the vinyl tube. The vinyl tube (inside

diameter 1.0 mm, outside diameter 1.4 mm, 20–25 cm long) acts as a flexible connexion with the needle mounted on the microsyringe. This latter, fixed on the table and mechanically driven, can release fluid at various output rates. This equipment is suitable for microinjections in both rats and mice, diameters and lengths of the free portions of middle sheath and point being changed according to the animal's size (Table 1). The animal to be injected is anaesthetized and held by the operator as previously illustrated<sup>13</sup>. The transauricular route to the hypophyseal capsule is opened by a needle as for hypophysectomy<sup>14</sup>. When the perforating needle is removed, the needle for micro-injections is introduced and gently pushed forward, through the open pathway, until the point penetrates the lateral portion of the pars distalis. The fluid can now be perfused into the hypophysis at a rate of 0.5–2  $\mu$ l./min, according to the size of the animal, for as long as is necessary. When required, the perfusion can be repeated. The needle is extracted at the end of each treatment. If the time elapsed between two treatments is no longer than 10 days, no further opening of the pathway to the hypophysis is needed. After each injection, the animals are given intraperitoneally tetracycline hydrochloride for 3 days at a daily dose of 0.05 mg/g body-weight. The accuracy of procedure can be checked by perfusing, before autopsy, a dye solution under the same conditions followed during the experiment<sup>4</sup>; the presence of a stained pituitary without any trace of dye outside the capsule (positive dye-test) will give evidence of the accuracy of previous treatment(s), since it was observed that the needle always follows the route of the first injection. A pilot experiment on rats and mice is reported. Twenty-four male immature Sprague-Dawley rats were treated for 5 min with saline, delivered at 1.2  $\mu$ l./min. The perfusion was repeated, every second day, for four times. At autopsy, the weight of testes, adrenals and thyroid of the animals with positive dye-test were taken and compared with controls. Forty-five male adult albino Swiss mice were treated only once with saline, given at 0.8  $\mu$ l./min for 5 min. The autopsies were performed 10 days after the treatment, as for the rats.

Table 1. DIMENSIONS OF THE CHANGING PORTIONS OF THE NEEDLES FOR TRANSAURICULAR INTRAPITUITARY MICRO-INJECTIONS IN RATS AND MICE OF DIFFERENT SIZE

Animal	Tail-length (cm)	Middle sheath		Gauge No.	Point Length of the offset portion (mm)
		Outside diameter (mm)	Length of the offset portion (mm)		
Rat*	<10.5	0.8	1.8	26	1.2
	10.5–14.5	0.8	2.0	25	1.5
	>14.5	1.0	2.2	25	1.8
Mouse†	<8.0	0.5	1.1	27	0.9
	>8.0	0.5	1.3	27	1.2

\* Sprague-Dawley strain.  
† Albino-Swiss strain.

The results of the sample experiment on rats and mice are given in Table 2. Single or repeated transauricular intrapituitary injections of saline cause no death, nor significant change in the weight of body, testes, adrenals and thyroid. Gross examination of the pituitary region never showed abscesses or haemorrhages. The number of positive dye-tests was satisfactorily high (rats: 96 per cent, mice: 93 per cent). On the basis of these results the transauricular route appears to furnish a new, safe and reliable

## PHARMACOLOGY

### Valency Investigations of Iron Dextran ('Imferon')

THE parenteral iron preparation 'Imferon', containing 5 per cent iron and 20 per cent dextran, is frequently used intravenously as well as by the intramuscular route for the treatment of anaemia due to iron deficiency.

Several theories have been put forward as to the chemical nature of this iron dextran preparation. These, broadly speaking, fall into two groups, namely, that: (1) ferric iron is chemically bonded to the dextran; (2) ferric iron is present as colloidal ferric hydroxide protected by the dextran. Recent investigations<sup>1</sup> using gel-filtration, ultrafiltration and ultracentrifugation have lent support to the theory that the iron is present as a ferric-dextran complex.

A striking feature of iron dextran is its very low intravenous acute toxicity ( $LD_{50}$ , 1,000 mg Fe/kg)<sup>2</sup>. This is probably a reflexion of a low ionic iron content. From *in vitro* haemolysis investigations of human red cells the ionic iron content was deduced to be about 1/300th of the total iron present<sup>3</sup>.

Polarography and high-voltage electrophoresis have been used to show the presence of very small amounts of loosely bound ferrous iron in 'Imferon' and to obtain an estimate of its concentration. At the same time, the overall results are in general agreement with the concept of a ferric-dextran complex.

The presence of ferrous iron in freshly opened ampoules of 'Imferon' was established by a high-voltage electrophoretic separation on 3 M.M. Whatman filter paper followed by detection with 4:7 diphenyl 1:10 phenanthroline. Separations suitable for quantitative evaluation were obtained using pH 5.6 acetate-acetic acid buffer solution and a potential gradient of 35 V/cm applied for 45 min. Evaluation of the developed ferrous-bathophenanthroline complex was obtained by: (a) planimetric scanning, and (b) elution of the complex with methanol followed by a spectrophotometric determination. The results for freshly opened ampoules of 'Imferon' showed the ferrous iron content to be in the range 50-100 mg/100 ml., whereas those which had been exposed to the atmosphere for several days contained no ferrous iron.

Table 1. HALF-WAVE POTENTIALS OF 'IMFERON', FREE FERROUS AND FERRIC IRON

	First wave ( $Fe^{3+} \rightarrow Fe^{2+}$ ) $E_1 \pm S.O.E. \uparrow$ (V) at 25°	Second wave ( $Fe^{3+} \rightarrow Fe^0$ ) $E_2 \pm S.O.E. \uparrow$ (V) at 25°
'Imferon'	-0.83	-1.39
Ferrous iron	—	-1.38
Ferric iron	+0.04	-1.38

\* 'Imferon', Eli Lilly Pharmaceuticals, Ltd.  
† S.O.E., standard calomel electrode.

The polarography of 'Imferon', free from ferrous iron, gave two distinct waves, as shown in Fig. 1.

The half-wave potentials of these waves together with those of ferrous and ferric iron are given in Table 1.

It is considered that these results indicate complex formation and that the ferric to dextran bonding is quite strong. The reduction of 'Imferon', at the dropping mercury cathode, probably occurs in two stages: (1) ferric-dextran complex  $\rightarrow$  ferrous-dextran complex + e; (2) ferrous-dextran complex  $\rightarrow$  iron + 2e.

Further confirmation is provided by the ratio of the diffusion currents, 1 to 2.02, compared with a theoretical value of 1 to 2.

The slight shift in half-wave potential from -1.38 V for ferrous iron to -1.39 V for ferrous-dextran indicates this is an extremely weak complex. It is probable that all the ferrous iron in 'Imferon' is present as this complex. The view that the ferrous iron is probably present in 'Imferon' as a weak ferrous-dextran complex is supported by the polarography of ferrous iron in the presence of 'Dextran C' (the dextran fraction, of average molecular weight 5,000, used in the manufacture of 'Imferon'). The ferrous iron half-wave potential was again displaced from 1.38 to -1.39 V. This was accompanied by a 20 per cent decrease in the diffusion current, which could not be accounted for by a change in the viscosity of the base electrolyte to which 'Dextran C' had been added.

The increase in the ratio of the diffusion currents in the first and second stages of reduction has been used to estimate the ferrous iron content. In the presence of ferrous iron the ratio is no longer 1:2; values varying from 1:2.09 to 1:2.17 were obtained, which correspond with ferrous iron contents of 50-100 mg/100 ml. These values are in agreement with those obtained by electro-phoresis.

This work has shown that the ferric iron is most probably present in 'Imferon' as a ferric-dextran complex and that ferrous iron is present, probably as an extremely weak ferrous-dextran complex usually in the concentration range 50-100 mg/100 ml.

In the anaesthetized cat, intravenous iron dextran induces hypotension of rapid onset and short duration, similar to that produced by small doses of acetylcholine

Fig. 1. Polarography of 'Imferon' (1 in 500 dilution in pH 5.6 acetate buffer solution)

or histamine<sup>4</sup>. Moreover, this fall in blood pressure is similar to that produced by ferrous iron. Indeed, there is a rough correlation between the hypotensive response of 'Imferon' and its ferrous iron content. Ferric iron, however, produces a different type of response; for an equivalent dose of ionic iron there is a smaller transient depressor response followed by a more sustained pressor response<sup>5</sup>.

The hypotensive effects of intravenous iron dextran were completely abolished at all dose-levels by reducing the speed of injection to 2.5 ml./min or by preliminary dilution of the iron dextran with isotonic saline.

So far as these observations apply to the clinical use of iron dextran, they emphasize the need for care in administering any form of iron intravenously.

J. S. G. COX

## HAEMATOLOGY

### Distribution of the $D_i^*$ Factor in Argentine Jews

FROM the initial results of their investigations about Diego antigen<sup>1,2</sup>, Layrisse and Arends supposed that it was a non-Caucasoid factor and related to the Carib Indians. Later studies on 2,600 Caucasoids from varied sources<sup>3,4</sup> corroborated that hypothesis on account of negative findings. Studies made in 1956 on Chinese<sup>5</sup> showed that the  $D_i^*$  gene belonged to Mongoloids rather than to American Indigenous.

A very low incidence in Russian and Polish individuals<sup>6</sup> of Tartarian origin suggests a Mongoloid hybridization on a Caucasoid stock.

Negroids do not carry the  $D_i^*$  gene, and the very low frequency which appears sometimes is attributed to a Mongoloid hybridization<sup>7</sup>.

Negative findings were also reported in South-west Asia including south, east and west India, Punjab and Pathans of Pakistan, Vedas of Ceylon<sup>8</sup> and Arabs of Iran. A low incidence of the antigen in Oraon of east India is attributed to Mongoloid neighbourhood.

About Jews there is an unpublished work<sup>9</sup> made by Gurevitch in Israel on 45 'Black Jews' of Cochin (India), with negative results.

Because of the widespread distribution in *golah*, the migratory life and high intermarriage rate of the Jewish people, I thought that the  $D_i^*$  factor might be detected in some frequency owing to a Mongoloid admixture.

I have analysed 400 specimens from 200 ashkenasim and 200 sephardim. Ethnic, cultural and other characters are described elsewhere<sup>10</sup>.

Blood specimens were taken by venous or digital puncture from unrelated Jews of La Plata, Burzaco and Buenos Aires cities; the donors were native and descendants from European, African and Asiatic origin<sup>11</sup>.

Indirect antiglobulin method with washed red blood cells in a 2 per cent suspension in normal saline and anti-

$D_i^*$  serum kindly provided by Dr. Miguel Layrisse from the Instituto Venezolano de Investigaciones Cientificas (Caracas) was used.

The factor was detected in 6 Jews and it was absent in the other 394 samples. It was absent in the 200 ashkenasim, and the positive findings belong to 3 natives from Esmirna (Turkey) and the other three are Argentine, from which two have both parents born in Esmirna and the last one has the father born in Urla—distant 40 km from Esmirna—and her grandparents both born in Esmirna.

Shown in Tables 1, 2, 3 and 4 are respectively: phenotypic and genic frequencies for Jewish people as a whole; Sephardim and Ashkenasim, independently; Sephardim of Turkey and Sephardim of Esmirna and neighbouring villages.

Table 1. PHENOTYPIC AND GENIC FREQUENCIES OF  $D_i^*$  FACTOR IN JEWISH PEOPLE (400 samples)

Phenotypes (%)	$D_i^*$ (a+)	1.50
	$D_i^*$ (a-)	98.50
Genes (%)	$D_i^*$	0.76
	$D_i$	99.24

Table 2. PHENOTYPIC AND GENIC FREQUENCIES OF  $D_i^*$  FACTOR IN SEPHARDIM AND ASHKENASIM

Sephardim (200 samples)	Phenotypes (%)	Ashkenasim (200 samples)
$D_i^*$ (a+)	3.00	0.00
$D_i^*$ (a-)	97.00	0.00
$D_i^*$	1.51	0.00
$D_i$	98.49	0.00

Table 3. PHENOTYPIC AND GENIC FREQUENCIES OF  $D_i^*$  FACTOR IN SEPHARDIM OF TURKEY (79 samples)

Phenotypes (%)	$D_i^*$ (a+)	7.59
	$D_i^*$ (a-)	92.41
Genes (%)	$D_i^*$	8.87
	$D_i$	91.13

Table 4. PHENOTYPIC AND GENIC FREQUENCIES OF  $D_i^*$  FACTOR IN SEPHARDIM FROM ESMIRNA AND NEIGHBOURING VILLAGES (THERE, MANTIN, URLA, AYDIN) (65 samples)

Phenotypes (%)	$D_i^*$ (a+)	9.67
	$D_i^*$ (a-)	90.33
Genes (%)	$D_i^*$	4.96
	$D_i$	95.04

According to the ABO system, Jewish people do not constitute a homogeneous group such as Armenians or Gipsies.

Studies performed in Israel<sup>12-13</sup> and Syria showed a definite but not wide difference between Ashkenasim and Sephardim. Jews of North Africa have more percentage of A and B than the neighbouring Arabs.

In India there are two communities, 'Black Jews' and 'White Jews' of Cochin, that are physically different. The latter show a high frequency of A because it is a highly endogamic community. 'Black Jews' have a higher proportion of O than the neighbouring low-caste Indians<sup>14</sup>.

Ashkenasim from Israel and Canada have a high frequency of  $R_1$  ( $CD_e$ ) and a higher frequency of  $R_2$  ( $cDE$ ) than North-European populations;  $d$  is lower than Centre- and North-European peoples.

Chown and Gurevitch have reported a high percentage for  $R_2$  ( $cDE$ ) which is of African origin.

Sephardim show a typically high level of  $R_1$  ( $CD_e$ ) and a low level of  $R_2$  ( $cDE$ ), but  $r$  ( $cde$ ) is higher than the Mediterranean values. The frequency of  $R_2$  ( $cDE$ ) is the highest one of any other Mediterranean people.

A Mediterranean and African component is deduced from Rh-Hr tests in Ashkenasim and Sephardim. According to the present findings on Diego factor in Sephardim we conclude that it may be admitted in hybridization with Turks, who belong to a Mongoloid origin.

Sero-anthropological investigations in Jews, including this work, contribute to sustain Mourant's hypothesis<sup>15</sup> that this ancient people resembles its local neighbours to a varying and sometimes a very close degree from a biological point of view.

I thank Drs. Miguel Layrisse and Tulio Arends for their kind co-operation and provision of anti-Di<sup>a</sup> serum.

### Some Antigen Similarities between Mouse Erythrocytes and Ehrlich Ascites Tumour Cells

It has been demonstrated that rabbit anti-mouse erythrocyte serum is capable of agglutinating ascites tumour cells<sup>1</sup>. Nothing is known, however, about the components of the erythrocyte which are responsible for producing the agglutinin; the present experiment was carried out to clarify this point, and mouse-specific ascites tumour cells and mouse erythrocytes were used.

Three female guinea-pigs were intramuscularly injected four times with 0.2 ml. erythrocyte ghosts of OF1 male mice with Freund's adjuvant every two weeks. Three other animals were treated in the same way with the ghosts of Ehrlich ascites tumour cells (EATC). The erythrocyte ghosts were prepared by Ponder's method<sup>2</sup>, and EATC were subjected to Ponder's procedure after homogenization. Two weeks after the last injection the antisera (the anti-mouse erythrocyte ghost and the anti-EATC ghost) were collected from the animals, and were treated at 56° C for 30 min before use. Almost the same technique was adopted for the agglutination test as was used in the previous investigation<sup>3</sup>. The erythrocytes tested were obtained from various strains of mice, such as A, CF1, C57BL, DDS and dd—though scarcely any difference was observed between the different strains on the titres resulted. The antisera were absorbed with equal volume of each absorbent shown in Table 1. The notation "crushed . . ." means that the absorbents with which the antisera were absorbed were prepared from Ponder's ghosts by pounding them with powdered dry ice using a mortar and pestle, and then washing with saline solution (Fig. 1a).

Fig. 1. Mouse erythrocytes used for the absorption ( $\times 1,000$ ). a, Crushed erythrocyte ghosts; b, erythrocyte ghosts by Ponder's method; c, intact erythrocytes.

Table 1. AGGLUTINATION OF MOUSE ERYTHROCYTES AND EHRLICH ASCITES TUMOUR CELLS WITH VARIOUS ABSORBENTS

\* Antisera were absorbed with equal volume of each absorbent at 37° C for 60 min.

† Equal volume of antiserum dilution and erythrocytes (2.5 per cent in phosphate buffered saline) or Ehrlich ascites tumour cells (5 per cent) incubated at 37° C for 60 min.

‡ Eryth. erythrocyte.

§ EATC Ehrlich ascites tumour cell.

|| Neg. no agglutination at serum dilution 1:2.

|| Crushed erythrocytes were obtained from Ponder's ghosts by pounding them with powdered dry ice in a mortar.

The observations and the findings are briefly summarized here: (1) The ghosts injected as antigens contain practically no water-soluble component. When the antisera are absorbed with normal mouse sera or ascites of tumour-bearing mouse, neither antiserum loses its agglutinating capacity—indicating that any water-soluble antigen is not concerned in these agglutination reactions.

(2) The anti-erythrocyte ghost serum is capable of agglutinating both the mouse erythrocytes and EATC, indicating that the EATC-agglutinogens are shared with erythrocyte ghosts and the cell surface of EATC. The anti-EATC ghost serum can agglutinate EATC strongly, but erythrocytes very weakly. If anti-erythrocyte serum is absorbed with EATC, its titre against erythrocyte does not decrease. When both anti-erythrocyte ghost and anti-EATC ghost sera are absorbed with intact erythrocytes, their titre against EATC never decreases; one may conclude that the haemagglutinogens are different from the EATC-agglutinogens.

(3) When both antisera are absorbed with intact mouse erythrocytes (Fig. 1c) or with Ponder's ghosts which keep their disk-like shape (Fig. 1b), they retain completely their EATC-agglutinating capacity. On the other hand, they almost lose the capacity when absorbed with crushed mouse erythrocyte ghosts. Both antisera do not, however, lose their agglutinating capacities when absorbed with crushed guinea-pig erythrocyte ghosts. In short, all the foregoing findings indicate that the mouse erythrocyte ghost and EATC contain at least common EATC-agglutinogens, and that the EATC-agglutinogens do not exist on the outer surface of the erythrocyte membrane, but rather seem to exist on the inner surface of the membrane. In other words, the outer surface of the cell membrane of EATC and the inner surface of the cell membrane of mouse erythrocyte closely resemble each other so far as their antigenicities are concerned.

## HISTOCHEMISTRY

## Retention of Nitrogenous Material in Unfixed Sections during Incubation for Histochemical Demonstration of Enzymes

THE dilemma of enzyme histochemistry is that if the tissue is not fixed, to avoid denaturation, the enzymes may dissolve out of the section into the incubation medium but, conversely, if the tissue is fixed to stop such loss of soluble enzymes, the fixation will inhibit activity and cause generalized denaturation. Thus, for most enzymes, it is argued that too much of the 'soluble' or lyo-form of otherwise bound enzymes<sup>1</sup> will be lost from unfixed sections during incubation in an aqueous medium; consequently it is considered advisable to fix the tissue prior to such incubation<sup>1-3</sup>. Although it is usually conceded that the histochemistry of dehydrogenases depends on the use of unfixed sections, some<sup>4</sup> have argued that even these should be studied in fixed tissue. Consequently it follows that the scientific basis of enzyme histochemistry must remain uncertain as long as a considerable loss of the activity to be investigated must be expected, whether this is caused by solution into the medium from unfixed sections, or from inhibition of activity produced by the preparative procedures.

This problem has been accentuated by the development of quantitative methods of evaluating enzyme activity in histochemical systems<sup>5</sup>. The full value of such studies will depend on the use of unfixed and well-preserved sections. On the other hand, Jones<sup>6</sup> has emphasized that, with his procedures, as much as 70 per cent of the 'fixed nitrogen' of his sections was lost in the first 5 min of incubation for succinic dehydrogenase activity, irrespective of the thickness of the sections used. Similarly, in their work on pentose-shunt dehydrogenases in unfixed sections, Gahan and Kalina<sup>7</sup> lost the whole content of these enzymes into the incubation medium after only 1 min. This was especially serious since an elevated level of activity of these enzymes seems to be a characteristic feature of invasive growth of cancer<sup>8</sup> and their loss into the incubation medium would render their histochemical study either impossible or meaningless. This problem has therefore been investigated in sections of rat liver, as was used by Jones<sup>6</sup> and by Gahan and Kalina<sup>7</sup>.

Female albino Wistar rats were killed with nitrogen. Pieces of liver about 0.5 cm<sup>3</sup> were plunged into hexane (B.D.H. 'free from aromatic hydrocarbons') maintained at about -70° C by an outer bath of solid carbon dioxide and alcohol. After not more than 1 min, the tissues were transferred, with chilled forceps, to a dry, corked tube, previously equilibrated against solid carbon dioxide in a Dewar flask, and stored in solid carbon dioxide for not longer than 2 days. Sections were cut at 8, 14 and 20  $\mu$  in a cryostat at about -30° C; the haft of the knife was cooled further by the presence of carbon dioxide ice packed around it. The sections were picked off the knife on to slides which were at the ambient temperature of the laboratory, and they were stored in a Dewar flask containing solid carbon dioxide until used, namely, for up to about 2 h. They were exposed to the air only long enough to dry them of obvious moisture before they were immersed in the relevant incubation medium at 37° C in microcells<sup>9</sup>.

The media contained 0.15 per cent neotetrazolium chloride (Sigma Chem. Co., U.S.A.); NADP (1 mg/ml.); glucose-6-phosphate sodium salt (1 mg/ml.) or 6-phosphogluconate trisodium salt (0.5 mg/ml.); 0.01 M potassium cyanide; 0.08 M calcium chloride in 0.05 M glycylglycine buffer at a pH of 7.6 for the former, and 8.4 for the latter, dehydrogenase. To these were added either 0, 10, 15 or 20 per cent w/v of polyvinyl alcohol (PVA). This substance was obtained from Bush, Beach and Segner Bayley, Ltd., London; the grade used was 'Polyviol M05/140':

this designation indicates that it has a 'medium' molecular weight, possibly of the order of 30,000, a viscosity of about 5 centipoises at 20° C when dissolved as a 4 per cent solution, and a saponification number of 140, indicating a low acetyl content. Sufficient activity for measurement was obtained after incubating for 20 min. The formazan produced by the dehydrogenation was eluted with 10 per cent *n*-heptanol in tetrachloroethane<sup>9</sup> and measured spectrophotometrically; the nitrogen content of the section was determined after digestion with 72 per cent perchloric acid (AnalaR grade)<sup>10</sup>. The area of the sections was calculated by planimetry of their image, projected by means of a photographic enlarger.

Table 1. THE EFFECT OF DIFFERENT CONCENTRATIONS OF PVA IN THE INCUBATION MEDIUM IN RETAINING NITROGENOUS MATERIAL

Section thickness ( $\mu$ )	Concentration of PVA (%)	mg N/unit area of section after incubating for		Amount of nitrogen (%) retained after incubating for	
		(a) Glucose-6-phosphate dehydrogenase	(b) 6-phosphogluconate dehydrogenase	(a)	(b)
8	0	12.5*	10.0 $\pm$ 1.2	56	45
8	10	18.2 $\pm$ 2.0	18.9 $\pm$ 2.6	82	86
8	15	26.4 $\pm$ 0.8	23.7 $\pm$ 4.6	120	108
8	20	23.4 $\pm$ 2.8	18.5 $\pm$ 1.4	100	88
8	No incubation	22.2 $\pm$ 3.6			
14	0	21.1 $\pm$ 3.9	16.5 $\pm$ 0.6	62	48
14	10	22.9 $\pm$ 1.4	22.7 $\pm$ 2.8	67	67
14	15	29.1 $\pm$ 3.5	32.6 $\pm$ 1.8	85	96
14	20	34.2 $\pm$ 4.4	35.2 $\pm$ 2.3	100	103
14	No incubation	34.1 $\pm$ 0.1†			
20	0	23.5 $\pm$ 7.7	24.0 $\pm$ 4.0	54	55
20	10	26.8 $\pm$ 2.5	30.1 $\pm$ 0.6	61	69
20	15	38.7 $\pm$ 0.5	34.1 $\pm$ 3.7	88	78
20	20	43.9 $\pm$ 3.5	48.5 $\pm$ 4.0	100	110
20	No incubation	43.8 $\pm$ 0.4			

\* In this experiment, only one value was obtained.

† These values exclude one section which was obviously of twice the normal thickness.

The results indicated that with 20 per cent PVA in the incubation medium no nitrogenous material was lost from the sections, irrespective of thickness. Reduction of the concentration to 15 per cent gave nearly complete retention, the excessive results with the 8  $\mu$  sections being due, probably, to the insensitivity of the method at such low concentrations of nitrogen. With the procedures used for preparing and incubating the sections, the loss of nitrogen was never greater than 50 per cent, even in the absence of PVA, while the addition of this inert molecule gave strikingly improved retention of the nitrogenous matter of all thicknesses of sections studied.

It seemed reasonable to make a direct test of whether the dehydrogenases were being lost from these sections into the incubation medium in the microcells, as was found by Gahan and Kalina<sup>7</sup>. It could have been argued<sup>7</sup> that the deposition of formazan found in the sections incubated even in the presence of 20 per cent PVA could have been produced by loss of the enzyme into the medium, where it generated NADPH, which then acted as substrate for tissue-bound diaphorase, or 'NADPH-neotetrazolium reductase'. To investigate this, sections of all three thicknesses were incubated for 5 min in the relevant incubation media lacking substrate and coenzyme to allow leakage of enzyme. They were then transferred to another microcell which contained fresh, complete media, and incubated for 20 min. When 10 per cent PVA was used the reduction in enzyme activity produced by such pre-incubation was just apparent; when 15 per cent PVA was used, no significant difference could be seen between sections which had been so treated and those which had been incubated normally. This was in marked contrast to the findings of Gahan and Kalina<sup>7</sup>, who lost all of both these dehydrogenases into the medium after 1 min; consequently no staining would have been expected when these sections, having been pre-incubated without substrate or coenzyme for 5 min, were transferred to a complete medium. This difference in resistance to pre-incubation, with different concentrations of PVA, correlated well with the retention of nitrogenous material as detected by chemical estimation of the nitrogenous matter.

Thus it seems possible that the presence of sufficient polyvinyl alcohol in the incubation medium may allow all the nitrogenous matter of the sections, and even 'soluble' enzymes, to be retained during the histochemical reactions for enzymes. This is possible without the use of chemical fixatives which will inactivate or denature the enzymes. Polyvinyl alcohol has been shown to be very inert cytochemically<sup>11</sup>; its effect seems to be comparable to that of polyvinylpyrrolidone in biochemical studies on isolated mitochondria<sup>12</sup>.

## PATHOLOGY

### Possible Relationship between Aortic Acid Mucopolysaccharides and Species-susceptibility to Experimental Atherosclerosis

DIFFERENCES between species in susceptibility to experimental atherosclerosis is one of the most stimulating problems of atherogenesis. Animal species less susceptible to cholesterol-induced atherosclerosis showed a greater lipolytic activity of the arterial wall<sup>1-3</sup> and a higher alpha-beta serum lipoprotein ratio<sup>4,5</sup> than susceptible ones. Moreover, the thyroid gland was found to be more active in the former group than in the latter<sup>6-8</sup>.

On the other hand, very scarce subendothelial ground substance was observed in normal guinea-pigs (a slightly susceptible species)<sup>9</sup>, whereas the reverse was observed in the intimal layer of the rabbit, which is notoriously highly susceptible<sup>11</sup>.

On the basis of the foregoing observations, the serum lipid pattern and the acid mucopolysaccharide (MPS) content of the aorta were studied in ten fasting healthy animals, of both sexes, of the following species: mouse, rat, hamster, guinea-pig, monkey, pig, dog, rabbit, pigeon and chicken. A battery of histological tests was used, since no one method is considered to be reliable by itself for the demonstration of acid MPS. Material which was metachromatic with Toluidine Blue and Azur A (the former on fixed and the latter on unfixed sections), and which gave a positive reaction with Alcian Blue and Hale's stain, modified by Rinehart and Abul-Hay, was considered to be acid MPS.

Our serum lipid findings did not show any significant correlation with specific differences in susceptibility to cholesterol-induced atherosclerosis. Almost similar alpha-beta serum lipoprotein ratios were found both in resistant (rat, hamster) and in susceptible species (pigeon, chicken). It might therefore be suggested that the efficiency of serum lipid homeostasis might be more significant in rela-

tion to the different susceptibilities. This homeostasis, indeed, is very efficient in the dog, the hamster, and the rat<sup>1,7,12-14</sup>, where a sustained hyperlipaemia cannot be induced by feeding a hypercholesterolic diet, whereas it is much lower in the rabbit and in the chicken, where serum cholesterol concentration can be increased by such a dietary manipulation, 30-fold and 12-fold, respectively<sup>17</sup>.

It is interesting that we have constantly found a parallel between the amount of acid MPS and the reported different species-susceptibility to cholesterol-induced atherosclerosis. Aortas of rat, hamster and mouse were found to be almost completely devoid of acid MPS, whereas aortas of chicken, pigeon and rabbit showed large quantities of acid MPS, intermediate levels being observed in guinea-pig, monkey, dog and pig.

Our histochemical findings, in agreement with the reported affinity between plasma lipoproteins and acid MPS of the arterial wall<sup>15-18</sup>, suggest that lipid deposition may more readily occur in arterial walls particularly rich in acid MPS. This may constitute at least a partial explanation of the species differences in susceptibility to experimental atherosclerosis.

### Comparison of the Physicochemical Properties of a Urinary Pigment of Human and Bovine Origin

A GENETICALLY determined syndrome has been described in the Holstein-Friesian strain of cattle which causes the calf to die in hypoglycaemia soon after birth. Affected calves of this strain are carried as many as 90 days beyond the normal 280 days of gestation. The genetic defect appears when the calf is homozygous for the trait. Both the heterozygous cow and bull are capable

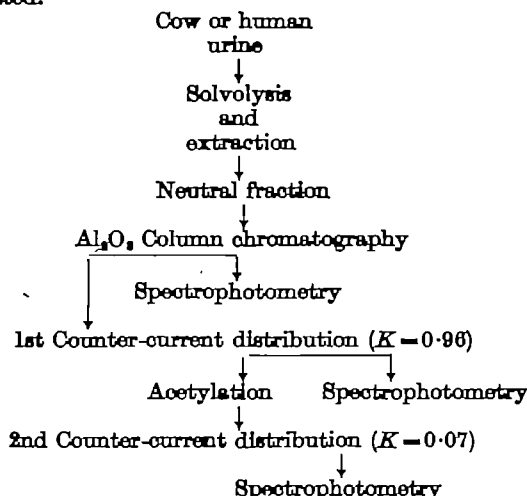

of generating a normal progeny if crossed with a non-affected animal; and the cow is capable of normal-length pregnancy if it does not carry a homozygous, affected calf. Holm<sup>1</sup> has reported that during an affected pregnancy the urine of these cows lacks a magenta pigment that can normally be detected in organic solvent extracts of hydrolysates of urines of non-affected cows. These findings are reported to be consistent enough to be used for the screening of the pregnant cows to detect those that carry an affected foetus.

Our experience in processing human urines for steroid hormone estimation is that a superficially similar pigment is present in human urines. A study was therefore undertaken to compare the physicochemical properties of the pigments of human and bovine origin.

Urines from four normal, non-pregnant Holstein-Friesian cows were obtained through the courtesy of Dr. Holm. Human pooled urine was used for comparison. All four of the bovine samples and a sample of pooled human urine of identical volume (400 ml.) were hydrolysed by solvolysis with sulphuric acid and ether<sup>2</sup>. The ether extracts were washed with 0.1 N NaOH in water, and evaporated to dryness. The neutral extracts were chromatographed on neutral alumina using increasing concentrations (0.02, 0.2, and 2.0 per cent) of ethanol in benzene as eluant. Both human and bovine magenta pigments were eluted at the same ethanol concentration (2 per cent). The chromatographically purified pigments were scanned in a Beckman 'DU' spectrophotometer. Both human and bovine pigments had closely similar spectra in the range of 4000–6000 Å, and a single absorption peak in the visible range with a maximum absorption at 5320 Å.

A 100 transfer counter-current distribution was run on the chromatographically purified materials using benzene/hexane/methanol/water (35:65:70:30) as the solvent system. The *K* calculated according to Craig *et al.*<sup>3</sup> was identical, *K* = 0.96, for pigments from humans and cows.

After counter-current distribution there was a shift in the absorbency maximum of both pigments to 5440 Å. The pigments were then acetylated in pyridine using <sup>14</sup>C-labelled acetic anhydride. Excess acetic anhydride was removed by extraction with ether and water. There was no appreciable change of colour after acetylation, and the maximum absorbency remained at 5400 Å. The derivatives were then re-run in 100 transfer counter-current. Both derivatives behaved identically, showing a new *K*, *K* = 0.07. After the second counter-current, demonstration of radioactivity in the pigments showed that they were acetylated.

While a statement about the identity of the human and bovine pigment must await their chemical characterization, the evidence so far obtained strongly suggests that they are identical.

Holm had previously reported that the pigment was recoverable from bovine urine after enzymatic hydrolysis with beta-glucuronidase. In preliminary work, we investigated the method of hydrolysis and extraction that would produce optimum yields. Three methods were compared using three aliquots of human urine from the same pool: (1) solvolysis with 2 N H<sub>2</sub>SO<sub>4</sub> using ether as the organic phase; (2) addition of concentrated HCl up to 15 per cent concentration, followed by 15 min reflux; (3) enzymatic hydrolysis with beta-glucuronidase ('Ketodase', Warner-Chilcott). The activity of the enzyme preparation was previously assayed, using the method of Talalay *et al.*<sup>4</sup>. All preparations were extracted, and the extracts were dried and taken up in benzene for chromatography on Al<sub>2</sub>O<sub>3</sub>. The eluted magenta pigments were then dissolved in a constant volume of absolute ethanol and their absorbencies were compared in a Beckman 'DU' spectrophotometer at 5320 Å. The highest yield was obtained from the H<sub>2</sub>SO<sub>4</sub>-ether solvolysis method. Using this figure as 100, HCl hydrolysis resulted in a recovery of 75 per cent, and enzymatic hydrolysis gave only 15 per cent recovery. We interpret these results to mean that in humans the pigment is not conjugated as a glucuronide to any great extent. As glucuronide conjugation in cattle has been reported by Holm, there is probably a species difference in this respect. It is conceivable that if the genetically determined condition of cattle has a parallel in human species, estimation of this pigment in urine may be of use in the detection of such a condition. Studies are in progress to assess the range of normal excretion of the pigment in man.

The investigation was supported by National Foundation grant PN5270.

## IMMUNOLOGY

### Serological Relationship between Adenovirus Haemagglutinins of Group 2

HETEROLOGOUS haemagglutination-inhibition (HI) antibody responses have recently been reported<sup>1</sup> to occur in volunteers inoculated with adenovirus type 26 or type 27. A significantly increased frequency of type 13 responses was observed among men inoculated with type 26 as well as high frequencies of reciprocal responses between types 26 and 27. These findings were interpreted as indicating the existence of antigenic relationships among these types. Heterologous responses to 17 other types also occurred; however, these were less frequent and were distributed in an apparently random fashion, so that additional antigenic relationships between individual serotypes could not be identified.

The various serotypes of adenovirus have been classified by Rosen according to the haemagglutination (HA) reactions of virus suspensions with rhesus erythrocytes and with rat erythrocytes<sup>2</sup>. The agglutinating serotypes are classified as follows: Group 1 includes serotypes that agglutinate rhesus erythrocytes only (types 3, 7, 11, 14, 16, 20, 21, 25, 28); Group 2, serotypes which completely agglutinate rat erythrocytes (types 8, 9, 10, 13, 15, 17, 19,

22, 23, 24, 26, 27, 29, 30); Group 3, serotypes which partially agglutinate rat erythrocytes (1, 2, 4, 5, 6). In this communication, the serotypes of the inocula used and of the antibody responses observed in the aforementioned investigation will be grouped according to the HA classification.

Details of the inoculation procedure and antibody determinations have been presented previously<sup>4</sup>. Briefly, seventeen volunteers were infected with adenovirus type 26 and fifteen volunteers with type 27; both these types are classified in HA group 2. Sera were collected prior to inoculation and 3-4 weeks later, and HI antibody determined<sup>4</sup>. A rise in antibody was considered significant if the titre increased from <1:10 to 1:10 or greater, or when any initially measurable titre increased at least fourfold.

In Table 1 are shown the frequencies of rises in antibody according to serotype, presence or absence of pre-existing antibody, and type of adenovirus inoculated. In Table 2 are shown the same data reclassified according to HA group and presence or absence of pre-existing antibody. The results in the two groups of volunteers were combined since both the inocula belong to HA group 2 and since the patterns of responses were quite similar. Excluded are homologous responses and heterologous responses previously interpreted as showing an antigenic relationship. Among paired sera in which pre-existing antibody was absent the percentage of responses directed against serotypes of HA group 2 was significantly greater than that of the responses to serotypes of HA group 1 ( $P < 0.01$ ) but were not significantly greater than the percentage directed against serotypes of group 3 ( $P = 0.07$ ). Among paired sera in which pre-existing antibody was present the percentage response was significantly greater in the serotypes of group 2 than in those of group 1, and in those of group 3 ( $P = 0.03$ ,  $P < 0.01$ , respectively). Comparison of the percentage response against group 2 serotypes with that against groups 1 and 3 combined shows that the former was significantly greater ( $P < 0.01$ ) regardless of the presence or absence of pre-existing antibody.

1	215	4	2	$\chi^2 = 20.8$	9	0	0
2	254	37	14	$P < 0.01$	24	10	42
3	135	10	7	$\chi^2 = 3.2$	0	0	0
				$P = 0.07$			$\chi^2 = 10.2$
							$P < 0.01$
1, 3	351	14	4	$\chi^2 = 18.0$	33	0	0
2	254	37	14	$P < 0.01$	24	10	42
							$\chi^2 = 18.0$
							$P < 0.01$

In summary, volunteers inoculated with adenovirus classified in HA group 2 exhibited heterotypic rises predominantly to serotypes also classified in group 2, which suggests that haemagglutinins of serotypes comprising the HA group may be serologically related. In this connexion, it should be noted that soluble haemagglutinins of HA group 2 as well as complement-fixing antigens and virus particles have similar chromatographic elution characteristics<sup>4</sup>. Moreover, using rabbit antisera in HI tests, Rosen has reported that heterotypic reactions occur to serotypes within HA groups rather than to viruses in different HA groups<sup>4</sup>.

In another investigation, volunteers were immunized with a soluble antigen prepared from a suspension of adenovirus belonging to HA group 3 (type 1). Preliminary results indicated a greater frequency of HI antibody rises against serotypes of group 3 than against serotypes of groups 1 and 2 (ref. 6).

## BIOLOGY

### Sex Determination and Genic Balance of *Ophryotrocha puerilis*, a Hermaphrodite Polychaete Worm

PURE male and female individuals were obtained from protandrous hermaphrodite strains of *Ophryotrocha puerilis* through selection for the prolongation of the male phase and for the anticipation of the female phase. Both the Atlantic and the Mediterranean sub-species of *O. puerilis* show polygenic sex determination<sup>1</sup>.

Observations have been made until recently on live specimens by looking for the appearance of oocytes which marks the beginning of the female phase. Pure males are characterized by the absence of any externally detectable oocyte during the whole life-cycle and pure females by the appearance of oocytes at the beginning of sexual maturity.

The normal gonadal differentiation has recently been studied through cytological investigation on individuals collected from natural populations or belonging to freshly established cultures of *Ophryotrocha*<sup>1</sup>. A firm basis for comparison was provided in this way for research on the gonadal differentiation of individuals belonging to lines which were selected either for the prolongation of the male phase (the so-called arrhenogenous lines) or for the anticipation of the female phase (the so-called thalygenous lines).

Marked deviations from the typical development of the female phase gonads—consisting mainly in a scarce differentiation between oocytes and nurse cells—have been observed in individuals from the fourth generation of arrhenogenous lines. A vacuolization of the cytoplasm in the primary and secondary spermatocytes, a peculiar

stickiness of the spermatids and irregularly shaped sperm-like structures are observed on the other hand in the young stages of the individuals from the fourth or fifth generations of thelygenous lines. Selection against male or female factors results, therefore, in deviation from the normal male or female differentiation during the stages that correspond to the male or female phases of unselected individuals. Unchecked proliferation of undifferentiated germ cells—which may fill out coelomic cavities of the worms—also often takes place during such stages, as shown in Fig. 1. The selection against the factors for either sex phase accounts for most of such results although the irregular production of undifferentiated germ cells in the place of normally built gonads still needs closer investigation.

Unexpected alterations of the maturation of the sex cells were observed, on the other hand, also in the phases that were favoured by artificial selection. Individuals belonging to the fourth or the fifth generation of arrhenogenous lines show, namely, some unmistakable alterations of the male sex cells which consist in the frequent appearance of piconotic nuclei and in the stickiness of the spermatids. Corresponding alterations of oogenesis—which consist in the formation of dwarf nurse cells and in altered spatial relationships between such cells and oocytes—are also observed in the fourth and fifth generations from thelygenous lines (Fig. 2).

It can be concluded, therefore, that selection against the female-determining factors and against the male-determining factors affects the sex phase against which selection is carried on, and also the sex phase that is apparently favoured by selection. Prolonged selection for either sex alters in other words the balance among sex factors in such a way as to alter the expression of both sexes.

Classic research work showed that given thresholds of sex balance must be reached in *Lymantria*, in *Drosophila* and in other organisms in order to obtain normal male or female phenotypes. It seems that the normal expression of the male and of the female phase can only be obtained in the hermaphrodite Polychaete *Ophryotrocha* within given limits of balance between male- and female-determining factors. Such limits appear, however, to be not sharply defined because such balance is not conditioned in *Ophryotrocha puerilis* by the presence of major genes or gene blocks which are located in the sex chromosomes of gonochorist species. The present results point, on the other hand, to the conclusion that factors of the complementary sex are necessary for the normal expression of either sex; which can be regarded as an extension of the classic principle of the genetic bipotency of the sexes.

The foregoing mechanism of sex balance reduces the fitness of the sex homozygotes and it functions as a

homeostatic mechanism which reduces sex variability in natural populations of *Ophryotrocha puerilis*.

### Red Water Bloom of a Dinoflagellate in Hillsborough Bay, Florida

WATERS of Tampa Bay, Florida, are regularly sampled for plankton in connexion with studies of the Florida red-tide organism (*Gymnodinium brevis*, Davis) and estuarine ecology. On May 5, 1964, various division stages and chain formations of an armoured dinoflagellate, *Ceratium furca* (Ehrenberg), were detected in the surface waters of Hillsborough Bay, an upper arm of Tampa Bay. The water samples were tinted brown and contained an average count of  $2.294 \times 10^4$  cells of *C. furca* per litre. Two weeks later, during an aerial survey of Tampa Bay, two staff biologists noticed patches of blood-red water in the upper portion of Hillsborough Bay. On May 25, during a special cruise in Hillsborough Bay, water in the entire upper portion of the Bay was discoloured with brownish and reddish patches. The most intense discoloration was noticed in areas protected from the wind. No mortality of fish or any other organism was observed in the field. Blue crabs, *Callinectes sapidus* Rathbun, and scaled sardines, *Barongula pensacolas* Goode and Bean, were actively swimming through the patches of blood-red water without showing ill effects.

All organisms were enumerated in the living state by counting techniques previously reported<sup>1</sup>. Before counting the organisms, two-litre Erlenmeyer flasks containing the samples were placed under a fluorescent light in the laboratory to concentrate phototropic organisms. *C. furca* concentrated in the meniscus of the flasks 15–30 min after exposure to the light, giving it a brownish-red tint. [In red water samples, *C. furca* was noted in very high concentrations, probably the highest on record for this dinoflagellate. The density of cells varied from  $2.24 \times 10^4$  to  $14.29 \times 10^4$  cells per litre.

Microflagellates, 4–7  $\mu$  in diameter, were also abundantly represented in the water samples. Furthermore, they were numerous in non-discoloured water from the same general area, suggesting that they played no part in the red discoloration. Some samples containing *C. furca* and these flagellates also yielded very small numbers of *Polykrikos* sp., *Prorocentrum miconis* Ehrenberg, *Gonyaulax* sp., *Coscinodiscus centralis* Ehrenberg, *Rhizosolenia setigera* Brightwell, *Biddulphia sinensis* Greville, and veliger-type larvae. These organisms were rare and did not contribute significantly to the intense colour.

A third cruise was made to the area on June 1. At this time the discoloured water contained blooms of *Scletonema costatum* (Greville) Cleve in addition to blooms of *C. furca*. The discoloration was much less pronounced than in blooms consisting principally of *C. furca*. Patches of blood-red water were absent, but the water retained a reddish hue. Concentrations of *C. furca* varied from  $3.1 \times 10^4$  to  $5.57 \times 10^4$  cells per litre. The cell density of *S. costatum* ranged from  $4.9 \times 10^3$  to  $1.45 \times 10^4$  cell chains per litre. By June 12, discoloured water had disappeared from the area

Fig. 1

Fig. 2

and only very low concentrations of *O. furca* and *S. costatum* were present in the samples. The area was inspected again on June 22, and no discoloration was noted.

A laboratory experiment was conducted to test light absorbency as an indicator of the degree of water coloration by *O. furca* cells. Aliquots from a bloom containing  $14.3 \times 10^6$  cells per litre were serially diluted from 100 per cent to 5 per cent by volume in 5 per cent increments. The diluted aliquots were then shaken slightly to distribute the organisms. Spectrophotometer cells of one-centimetre path length were filled with the dilution, and the absorbency measured at 400 m $\mu$ . The pattern of the observed absorbencies agreed with the volume dilutions. A maximum of 0.180 was noted for the 100 per cent volume and 0.018 for the 10 per cent volume.

To test the toxicity of a *Ceratium furca* bloom on fish, several specimens of *Lagodon rhomboides* (Linnaeus), 95–112 mm (FL), *Paralichthys albigutta* Jordan and Gilbert, 104–5 mm (FL), and a specimen of *Chaetodipterus faber* (Broussonet), 125 mm (FL), were selected. These fish were kept for 36 h in an aerated 15-gal. tank containing high concentrations ( $14.29 \times 10^6$  cells per litre) of this dinoflagellate. The fish remained active and behaved normally throughout the experiment. After the experiment, all *O. furca* were deliberately killed. As the dead dinoflagellates settled to the bottom of the tank, the water regained its normal transparency.

The observations presented indicate that unusually dense concentrations of *O. furca* were responsible for the blood-red discoloration, and that there was no toxic effect on fish. The possibility that discoloration was also caused by the bloom of *S. costatum* cells is remote since the samples taken on May 25 from blood-red patches of water contained only blooms of *O. furca*. In water samples from areas of *O. furca* and *S. costatum* blooms, the intensity of discoloration was less than in water containing only *O. furca* blooms. *S. costatum* is one of the most abundant diatoms in Hillsborough Bay. Each year, blooms are observed throughout the winter and into the spring months. No water discoloration has been associated with *S. costatum* blooms.

The association of *O. furca* blooms and water discoloration in Florida is reported here for the first time. One of the more frequently observed sea-water discolorations along the south-western coast of Florida is commonly known as 'red tide'. This is a natural fish-killing phenomenon and is always associated with discoloured water containing dense populations of *Gymnodinium breve*, a naked dinoflagellate<sup>1</sup>. The discoloration of water during the outbreaks of the Florida red tide may vary between brown, red and green. Another discoloration of biological origin in Tampa Bay and off the west coast of Florida was reported by Hutton<sup>2</sup>. He did not mention the colour of the water, which he associated with blooms of *Gymnodinium splendens* Lebour. He described the discoloration in offshore waters as streaks of reddish-brown water, approximately one mile in width. The water contained  $3.5 \times 10^4$  specimens of *Acartia tonsa* Dana per litre. *Labidocera aestiva* was also present in Hutton's samples but in smaller numbers than *A. tonsa*. Hutton observed no damage of fish in connexion with the blooms of *G. splendens*, *A. tonsa* or *L. aestiva*.

A blue-green alga, *Skujella* (*Trichodesmium*) *thiebauti* De Toni, is associated with brownish discoloration in coastal waters of south-western Florida. Fish kills caused by this alga have not been reported from the area.

## Relationship between the Ovary and Oviduct in the Domestic Hen

DURING the course of experiments designed to investigate the relationship between ovulation and nesting behaviour in the domestic hen, a number of hens were operated on to form a fistula in the magnum. While the technique of this operation has been described elsewhere<sup>1</sup>, certain observations on these hens, cogent to the problem of egg production and reproduction in general, are given here.

In each of four birds the fistula was so made that any ovum entering the infundibulum and descending in the oviduct would be shed externally through the fistula on the ventral abdomen. The fistula was covered with cheese cloth, secured around the bird's back by safety pins. Each bird was kept in an individual pen with a number of trapnests at her disposal.

In general, ovulation in this species is followed by nesting behaviour, the form of which depends on the environment. In the pens in which these birds were kept, a normal hen first exhibits some restlessness, then 'examines' several nests for a variable time, possibly returning to feeding and other activities between 'nest examination'; finally, she enters a trapnest and settles into a sitting position. In the operated birds, a proportion of nestings, that is, 'nest examination', entry and sitting on the nest, were unaccompanied by shedding of an ovum through the fistula. These nestings not preceded by ovum shedding occurred during the winter months shortly before the birds went off lay or when they were coming back into lay. At these times the combs and wattles indicated that the ovary was active, and the birds were generally in a laying condition; but examination through the fistula showed that the oviduct was in a shrunken state. Thus, it appeared that the ovary and oviduct were out of phase, and this suggested that internal laying had occurred during these periods. At post-mortem each bird examined had a fully active ovary with many mature follicles and a mass of yolk material was present in the body cavity. The oviducts were clearly incapable of dealing with the shed ova. This anomaly is not likely to have been due to the surgery, for nesting without oviposition has been found to increase at similar periods in normal birds, the egg-laying and nesting records of which have been closely observed (Fig. 1).

These observations appear to indicate that two separate mechanisms are involved, one for the control of ovarian activity and the other for the control and maturation of the oviduct. In cats, Michael<sup>2</sup> has shown a comparable

Fig. 1. Nestings without oviposition as a percentage of total nestings; that is, percentage loss of possible eggs due to the oviduct not engulging the shed ovum.

separation between oestrous behaviour and vaginal and uterine state. Young *et al.*<sup>2</sup>, working with guinea-pigs, also found ovarian activity and oestrous behaviour to be imperfectly correlated, and, furthermore, their results show that the relationships between the three measures of ovarian activity were also variable. It is very probable that during the laying season of a bird a number of potential eggs are lost through lack of co-ordination between the ovary and oviduct.

### Floral Meristem-organizing Gradient in Tobacco Stems

THE existence of a gradient reflecting the ability to form flower buds, along the stems of tobacco plants (var. 'Wisconsin 38'), has been previously reported<sup>1</sup>. Internode fragments, cultured on a simple medium devoid of growth substances, produce a callus which reflects this gradient in terms of its tendency to organize. Fragments isolated from the basal part of the stem produce only callus, those from the vegetative mid-part of the stem may produce 2 or 3 vegetative buds<sup>2</sup>, whereas those isolated from the flowering part of the stem form calluses producing 10 to 20 flowering buds<sup>3</sup>. The higher the fragments are cut, the greater the ratio of flower to vegetative buds per callus.

The gradient thus observed on internode fragments cultured *in vitro* probably exists in the intact flowering plant. The problem is to provoke a tissue proliferation *in vivo*, such that it bears newly formed organs, which would enable one to determine whether organ formation reflects such a gradient. The fact that tumours induced by certain strains of *Agrobacterium tumefaciens* can organize<sup>4-6</sup> might prove useful in uncovering the existence of a gradient *in vivo*.

Fig. 1. Floral organogenesis on crown-gall tumour developed on *Nicotiana tabacum*, 'Wisconsin 38'

*Agrobacterium tumefaciens* (Strain T37) was injected into the internodes of flowering *Nicotiana tabacum* plants (var. 'Wisconsin 38'). At the inoculation sites, tumours developed and organized, the nature of the organization depending on the level of the stem at which the injection was made. On the flowering part of the stem, the tumours were small, and bore organs some of which produced flower-buds (Fig. 1). Just underneath the inflorescence the tumours developed small stems with leaves and then flower-buds. Lower still, teratologic organoids were observed, and further towards the base of the stem only unorganized tumours were obtained. A flowering gradient was thus observed, and the gradient apparently exists in the intact plant as well as in isolated fragments.

Both *in vivo* and *in vitro*, the tendency for teratomatous tissue of tobacco to organize depends on the hormonal milieu in which such tissue is growing, particularly in respect to auxin and gibberellin<sup>6</sup>. For normal tobacco callus, the kinins also appear to play a critical part in bud organization<sup>7</sup>. The gradient of organogenesis described in these preliminary experiments is therefore presumably due to a gradient of hormone concentrations inside the plant, but whether the flowering of the organs formed on the inflorescence-axis is entirely a hormonally controlled process cannot be decided until floral organogenesis can be experimentally induced with specific hormones. I thank Dr. Manigault for kindly supplying the bacterial strain.

### Influence of Ioxynil on the Photo-reduction of Endogenous Plastoquinone by Isolated Chloroplasts of *Vicia faba* L.

ALTHOUGH plastoquinone (a 2,3-dimethyl *p*-benzoquinone, with a C<sub>4</sub> side chain at C<sub>6</sub>) was first isolated in 1946 by Kofler from alfalfa grass, it did not excite much interest until Crane<sup>1</sup> extracted the compound from the chloroplasts of green leaves. Plastoquinone (PQ) was first implicated as a participant in photosynthetic electron transport systems by Bishop<sup>2</sup>. Recently, Redfearn *et al.*<sup>3</sup> have shown plastoquinone to be an intermediary electron carrier in the photosynthetic system, being a part of the light-dependent water-splitting mechanism as outlined by Duyssens *et al.*<sup>4</sup>. We have recently reported<sup>5</sup> that ioxynil (4-hydroxy-3,5-diiodobenzonitrile)<sup>6</sup> inhibits photophosphorylation and the accompanying reduction of pyridine nucleotide by chloroplasts. The results reported have been improved in recent months to give 50 per cent inhibition of both processes at a concentration of ioxynil of  $5 \times 10^{-4}$  M. In an attempt to elucidate the action of ioxynil on the photosynthetic electron transport system, the ability of chloroplasts to photo-reduce endogenous plastoquinone was investigated.

Chloroplasts were isolated and washed as previously described<sup>5</sup>. The technique involving the measurement of plastoquinone was that described by Redfearn<sup>3</sup> in which the steady-state oxidation-reduction levels are measured. Replicate tubes contained 0.05 M Na/K phosphate buffer pH 7.0 containing 0.01 M potassium chloride, and chloroplasts equivalent to 1 mg chlorophyll/ml. in a final volume of 3.0 ml. Other chemicals were added as required. The tubes were illuminated from both sides by two

250-W photoflood bulbs, using water filters to eliminate over-heating. After 5 min, a solution of pyrogallol in methanol ( $-20^{\circ}\text{C}$ ) was added to prevent re-oxidation of the reduced plastoquinone formed, during the extraction procedure. The tubes were removed from the light, and an equal volume of  $40^{\circ}\text{--}60^{\circ}$  petroleum ether was added. The plastoquinone was extracted by partitioning the petroleum ether layer with 95 per cent methanol. The petrol layer was evaporated to dryness under vacuum and the residue dissolved in 3 ml. of pure ethanol. The spectrum of the extract was determined on a Unicam S.P. 800 recording spectrophotometer between 220–310 m $\mu$ , and the value of  $\Delta E$  at 255 m $\mu$ , after reduction with a few grains of  $\text{NaBH}_4$ , was taken as a measure of the amount of plastoquinone in the oxidized form.

*o*-Phenanthroline, a known inhibitor of the Hill reaction, was used as a reference in comparing the activity of ioxynil in inhibiting the photo-reduction of plastoquinone. The results are shown in Table 1.

Table 1		
Additions	Incubation	% PQox
None	Dark	87.5
None	Light	75.0
Ioxynil	Dark	86.2
Ioxynil	Light	87.5
<i>o</i> -Phenanthroline	Dark	95.8
<i>o</i> -Phenanthroline	Light	Photo-oxidation

The final concentrations of ioxynil and *o*-phenanthroline were  $5 \times 10^{-4}$  M.

From Table 1 it can be seen that 12 per cent of the plastoquinone present becomes reduced on illumination, while no similar reduction was observed when the mixture was incubated with either ioxynil or *o*-phenanthroline. Indeed, a photo-oxidation was observed in several instances with *o*-phenanthroline. This observation has also been noted by other workers<sup>7</sup>. Since plastoquinone is considered to be the acceptor of electrons from the chlorophyll *b* mediated reaction involving the splitting of a water molecule, both *o*-phenanthroline and ioxynil appear to inhibit this reaction. The net result is that plastoquinone remains in the oxidized form, instead of being reduced.

Table 2			
Additions	Incubation	% PQox	
None	Dark	87.5	88.5
None	Light	75.0	68.5
Ioxynil	Dark	87.5	91.0
Ioxynil and ascorbate and DOPIP	Light	87.5	80.0
<i>o</i> -Phenanthroline	Dark	Photo-oxidation	95.8
<i>o</i> -Phenanthroline and ascorbate and DOPIP	Light	56.2	50.0
Ascorbate and DOPIP	Light	43.8	45.9

The final concentrations of ioxynil, ascorbate, 2,6-dichlorophenolindophenol and *o*-phenanthroline were  $5 \times 10^{-4}$  M,  $1.6 \times 10^{-3}$  M,  $8 \times 10^{-4}$  M and  $5 \times 10^{-4}$  M respectively. The chlorophyll concentrations in the chloroplast suspension used were: (A) 1.01 mg/ml; (B) 1.16 mg/ml.

The effect of adding ascorbic acid/dichlorophenolindophenol (DOPIP) was investigated in an attempt to by-pass this apparent site of inhibition. The results are shown in Table 2.

The effect of ascorbate on the system is to generate extra reducing equivalents. Since there is a vast photo-reduction of plastoquinone in the light in the presence of ascorbate, compared with the control, there must be untapped plastoquinone present which is not reduced under normal conditions. This reduction in the presence of ascorbate is only slightly inhibited by *o*-phenanthroline, indicating that the electrons donated by ascorbate are by-passing the site of inhibition. This situation, however, does not occur in the presence of ioxynil under the same conditions.

It has been suggested by Witt *et al.*<sup>8</sup> and by Trebst<sup>9</sup> that there may be more than one site involving plastoquinone in the photosynthetic electron transport chain. Our implication is that, this being the case, it would appear that ioxynil has a blocking action at more than one site of plastoquinone, since there is no enhanced reduction of plastoquinone in the presence of ascorbate. This may be

Fig. 1

shown in Fig. 1, set out on the basis of redox potentials, according to Arnon<sup>10</sup>.

In the light of these results, ioxynil, apart from inhibiting the reaction  $h\nu^2$  as does *o*-phenanthroline and 3-(3,4-dichlorophenyl)-1,1-dimethylurea (DOMU), also has a blocking action at some other part of the chain. It may be the case that plastoquinone is also located at those parts of the chain indicated by X and Y in Fig. 1. If this is so, then this may be the explanation for the enhanced reduction of plastoquinone by ascorbate in the light, and also the added sites of action of ioxynil. A second site for plastoquinone has been suggested by Redfearn for this enhanced reduction of plastoquinone in the presence of ascorbate. The results described would seem to confirm this suggestion. This being so, plastoquinone could presumably function at X or Y, two points along the cyclic phosphorylation pathway, which we already know to be inhibited by ioxynil.

## MICROBIOLOGY

### Post-irradiation Recovery of *Escherichia coli*

RADIATION sensitivity of *Escherichia coli* strains is influenced by conditions for growth prior to and after radiation exposure. Stapleton and Engel<sup>1</sup> have shown that *E. coli* B/r (CSH) grown in a buffered-peptone medium developed higher X-ray resistance. The cells grown in rich medium, however, might have become more exacting in their nutritional requirements and their recovery was limited on basal media<sup>2</sup>. At the same time, the recovery of ultra-violet or X-irradiated cells was higher when they were subjected to sub-optimal growth conditions<sup>3-5</sup>.

It can, therefore, be assumed that the cells grown in rich medium may withstand radiation injury better than those grown in basal medium; but the latter may possess greater capacity for recovery. To test this hypothesis, *E. coli* strain B was grown in buffered-peptone medium<sup>1</sup> and in Davis's glucose-salts medium<sup>2</sup>. After irradiation, the survivors were further subjected to cold starvation in phosphate buffer at 7° C for 14 days. The effects of such stresses were measured by the loss of colony-forming ability.

*E. coli* B was grown in peptone broth for 18 hours at 37° C on a shaker. This corresponded to the terminal logarithmic phase of the culture. In glucose-salts medium, 21 h were required to reach the same phase. Both cultures were centrifuged and washed twice with 0.067 M phosphate buffer. The washed cells were then resuspended in the same buffer to give approximately 10<sup>8</sup> cells/ml. by adjusting the optical density to a standard value. Aliquots of these suspensions were irradiated with γ-rays to receive 10 krad from a cobalt-60 source (dose rate: 63.3 krad/h). Irradiation was carried out in air with the temperature maintained at 18° C to minimize cold sensitization<sup>3</sup>. This resulted in 99 per cent inactivation of the initial population.

Both irradiated and non-irradiated cell suspensions were further diluted in buffer to give approximately 1,000 cells/ml. and stored at a sub-growth temperature of 7° C (ref. 8). Daily samples were drawn from this suspension for 14 days and the viable counts were determined by simultaneously plating 0.1 ml. portions on solidified peptone agar and glucose-salts agar. Platings were made in triplicate from two identical experiments and the standard error was calculated from total of 6 plates each. All plates were incubated at 30° C (ref. 9) for 24–48 h. No additional colonies developed after this period.

The buffer suspended *E. coli* B was fairly stable at 7° C. The cells grown in buffered peptone retained approximately 60 per cent of their initial viability after 14 days while cells grown in glucose-salts remained 40 per cent viable after the same period (Tables 1 and 2). The cold starvation, therefore, appears to exert only a mild stress to healthy cells.

The cells were grown in buffered peptone medium for at least 2 weeks before they were used as inocula. Despite

Fig. 1. 10 krad γ-irradiation surviving *E. coli* B grown in buffered peptone broth and held in 0.067 M phosphate buffer at 7° C. ●, Plated on peptone agar; ○, plated on glucose salts agar

this, the peptone-grown cells formed nearly equal number of colonies on glucose-salts agar (Table 1). This indicates that the peptone-grown population was free of auxotrophs.

During cold starvation, the peptone-grown cells increased in number for the first 2–3 days. *E. coli* is known to carry on metabolism at 0° C at a much reduced rate<sup>10</sup>. Although no normal growth was expected to occur below 8° C, the reduced rate of endogenous metabolism may have been able to complete some division initiated before gathering the cells. Since no similar phenomenon was encountered with cells grown in glucose-salts, such delayed division might have been carried out by metabolites accumulated during growth in the richer medium.

The radiation survivors behaved differently. A steady decrease of viable cells was noted during cold starvation when peptone-grown cells were enumerated on the same medium (Fig. 1). The same cells plated on glucose-salts agar did not show this steady decline. Viable counts on glucose-salts agar were always higher than on peptone agar. The viable counts on glucose-salts agar remained relatively constant for about 10 days, while the peptone agar counts declined rapidly, and approached the same level as those on peptone agar on the fourteenth day.

Since the cold starvation was not sufficiently strenuous to normal cells, the rapid decline of viability among the radiation survivors on peptone agar may be due to a continuous loss of sub-lethally injured cells from the population. If such damage was on the metabolic potential as was indicated with freezing<sup>11</sup>, phenol treatment<sup>12</sup> and with X-ray reported by Stapleton *et al.*<sup>3</sup>, the recovery on peptone agar should have been superior to glucose-salts.

Alper and Gillies<sup>3</sup>, Stapleton *et al.*<sup>4</sup> and Gillies and Alper<sup>5</sup>, however, have shown that the sub-optimal recovery conditions were conducive for a greater recovery of irradiated *E. coli*. The slower rate of growth in glucose-salts medium then may have been responsible even for the recovery of peptone-grown cells. The lag period in peptone broth was approximately 40 min, while 4 h were needed before turbidity could be detected in glucose-salts broth. Although the lag period on solid recovery medium could not be measured, similar difference in the length of this period would be expected. It is conceivable that peptone-grown cells should have required even a longer lag period on glucose-salts. Such prolonged recovery period, therefore, might have enabled the damaged cells to recover even if it required an adaptation to a minimal medium. Such adaptation could have been possible because the peptone-grown population was free of auxotrophs. The nature of such injury is being further investigated.

The cells grown in glucose-salts, after irradiation, could be recovered equally well on either peptone or glucose-salts agar (Fig. 2). The more rapid viability loss of the non-irradiated population during cold starvation indicates, however, that the glucose-salts-grown cells possessed lesser

14	0.57 ± 0.06	38.0	0.57 ± 0.06	38.0

\* The maximum count obtainable from identically treated samples.

Fig. 2. 10 krad  $\gamma$ -irradiation surviving *E. coli* B grown in glucose-salts broth and held in 0.067 M phosphate buffer at 7° C. ●, Plated on peptone agar; ○, plated on glucose-salts agar.

survival potential under this stress. The cells grown in glucose-salts were more sensitive to radiation than those grown in peptone (Table 3). The relative stability of irradiated cells during cold starvation then might have been due to such population containing a lesser number of sub-lethally injured cells. If we assume that the rapid growth following injurious treatments has resulted in forced recovery, cells grown in glucose-salts might have been able to compensate for such stress by having diversified enzymatic machinery.

Table 3. PERCENTAGE INITIAL SURVIVAL OF *E. coli* B AS INFLUENCED BY PRE-IRRADIATION GROWTH MEDIA AND BY POST-IRRADIATION\* RECOVERY MEDIA

Growth media (broth)	Recovery media (agar)	Glucose-salts
Buffered-peptone	1.36 $\pm$ 0.13	1.63 $\pm$ 0.23
Glucose-salts	0.73 $\pm$ 0.07	0.63 $\pm$ 0.09

\* Irradiated in 0.067 M phosphate buffer.

It appears that sub-lethally injured *E. coli* require a slow recovery process which is not compatible with the rigour demanded of optimum growth. Such injured state could be reversed even after prolonged starvation at lower temperature. The nature of this injury, nevertheless, does not appear to be an impaired metabolic capacity.

## VIROLOGY

### Immune Adherence to Tissue Culture

HAEMADSORPTION is often used to detect virus infections of tissue cultures. This technique is not, however, of universal application because the phenomenon cannot always be elicited even in cases where the virus is known to cause haemagglutination.

Another type of agglutination of primate erythrocytes by micro-organisms and other antigens can be demonstrated if both a specific antiserum for the antigen and complement are included in the mixture. This phenomenon has been called by Nelson<sup>1</sup> 'immune adherence'.

During attempts to cultivate several group B arboviruses in chick embryo tissue cultures growing on poly-

Table 1. IMMUNE ADHERENCE TO TISSUE CULTURE

Mixtures	Adherence (positive or negative) to chick embryo lung cells growing on polythene
1 Human O RBC + antiserum + O'	+
2 Human O RBC + antiserum	—
3 Human O RBC + O'	—

\* Sheep, rabbit, guinea-pig, chicken or goose erythrocytes.

thene<sup>2,3</sup>, I was unable to observe any cytopathic effect and there was no adsorption of goose erythrocytes in the pH range used for the demonstration of haemagglutination by these viruses. I was thus led to consider immune adherence. To discover whether this was practicable, an antiserum for chick embryo cells was prepared by the intramuscular injection into guinea-pigs of a suspension of chick chorio-allantois. 0.1 ml. of a mixture of washed human O erythrocytes in physiological saline, the antiserum inactivated at 56° C for 0.5 h, and guinea-pig complement (O'), was allowed to sediment for 0.5 h at 37° C on to cultures of chick embryo lung cells growing on disks of polythene. The cultures were then washed in a beaker of saline, mounted in 5 per cent glycerol in saline on a microscope slide and examined with phase contrast illumination. The erythrocytes were firmly adherent to the cell sheet. Adherence occurred at room temperature or at 37° C but not at 4° C. The optimum concentration of erythrocytes was found to be 0.5 per cent, and by titration, the optimum amounts of antiserum and of complement were chosen to be four times the minimum amounts required to allow immune adherence. Table 1 shows the effects of omitting or altering components of the mixtures. The phenomenon is not a complement-dependent mixed aggregation<sup>4</sup> because adhesion still occurs after both the antiserum and the complement have been absorbed with human O erythrocytes. To demonstrate immune adherence to virus-infected tissue cultures, immune sera to a neurotropic strain of yellow fever virus were prepared in guinea-pigs by the intranasal inoculation of a mouse brain suspension of live virus. Two weeks after an inapparent infection, the guinea-pigs were bled. Chick lung cultures growing in 'Medium 199' on disks of polythene were infected with yellow fever virus: the disks were examined after 24 h. Mixtures of human O erythrocytes, inactivated immune serum and guinea-pig complement were allowed to sediment on to the disks and immune adherence occurred (Fig. 1). No adherence was observed to disks of uninfected lung cultures nor to infected cultures with any of the mixtures numbered 2, 3, 4 in Table 1. The sensitivity of this method of virus assay requiring only 24 h was of the same order as titration by inoculation of suckling mice. Similar results

Fig. 1. Immune adherence of human O erythrocytes after infection of a tissue culture of chick lung with a neurotropic strain of yellow fever virus. ( $\times$  c. 840)

were obtained with two other arboviruses using in each case the specific antiserum.

Apart from the use of immune adherence in applications analogous to the example described or in cases where the virus does not cause haemagglutination, the same technique may prove useful for the detection of new antigens in cells transformed by oncogenic viruses. Immune adherence to tissue cultures might also lead to the discovery of new viruses. Material for culture could be obtained from an individual in the acute stage of a virus infection and specific immune serum would be provided later by the same individual in convalescence.

## CYTOLOGY

### Electron Microscopic Observations of Human Chromosomes Isolated by Micrurgy

THE elucidation of the structure of the human chromosome is of basic biological importance. A more detailed understanding of the mechanisms involved in utilization, duplication, and transfer of genetic information requires a concept of the physical manner in which this information exists during these three processes. To this end a number of models of chromosome structure have been proposed. These models have been based largely on light microscopic observations and electron micrographs of fragments of chromosomes of various plants and animals<sup>1,2</sup>. So far, none of these models has been universally accepted as being representative of the human chromosome.

Published electron micrographs of mammalian mitotic chromosome structure have shown filaments of certain thicknesses, but so far they have failed to reveal credible reproducible configurations at the various levels of structure in any given chromosome<sup>3-5</sup>. I believe that the problem lies in the difficulty of fixing and retaining geometrical relationships of structures composed of widely different chemical entities such as DNA and protein. In an effort to pass gently from the physiological state to the dry preparation for electron microscopic observation, the following variation of the technique of McClendon<sup>6</sup> has been devised.

Chang liver cells *in vitro* are pre-treated with colchicine and mounted in an open-ended chamber for micrurgical procedures. The chamber is filled with a physiological chemically defined medium into which the chromosomes are to be isolated. A cell in metaphase is located and an incision is made in its cytoplasmic membrane. During the following 2 min or so the mitotic apparatus slips out of the cell through the incision. Next the tips of two microneedles are carefully inserted into the isolated mitotic apparatus in an effort to grasp the spindle. The microneedles are then gently pulled away from each other just enough to separate the chromosomes along lengths of the spindle which is then attached to the cover-slip. During this process several chromosomes are inadvertently damaged or destroyed by being stretched or smeared on to the cover-slip. However, many of the other chromosomes are readily identifiable as belonging to one of the various groups of the human set<sup>7</sup> and show neither damage nor any non-chromosomal material (contamination) which can be seen with the light microscope (Fig. 1). At the next step, which is fixation, any of a variety of fixatives may be used. At this time, any protein in the medium around the chromosome may precipitate and care must be exercised

Fig. 1. Phase contrast micrograph of human chromosomes isolated from Chang liver cell by micrurgy. The background was printed to medium grey to show the lack of non-chromosomal material in this fixed preparation.

to remove as much as possible without damaging the chromosomes. Finally, the points of attachment of the spindle to the coverslips are loosened and segments of spindle with attached chromosomes are placed on a 'Formvar'-coated grid, at which time the fixative may be removed and replaced by a solution which undergoes minimal change of pH and salt concentration as the preparation is dried in air. At this time the preparation is ready for examination with the electron microscope.

Human chromosomes prepared in this fashion and examined with the electron microscope show considerable structural detail. Although there appear to be structural variations along the length of at least some chromatids and between some chromosomes, preliminary analysis of several chromosomes suggests the following generalizations.

The centromere has been clearly seen as a quasitriangular structure about 7000 Å across its largest dimension (Fig. 2). Occasionally the centromere may appear heart-

Fig. 2. The centromere of this chromosome is clearly seen. It also appears obvious that at least some of the chromosome fibrils extend through the region occupied by this centromere.

Fig. 3. A schematic representation of general features of human mitotic metaphase chromosomes

shaped and the indentation is interpreted as part of the early stages of division (Fig. 3).

From the region of the centromere there appears to extend through the length of each chromatid a rather large (about 1200 Å thick) filament having little electron density. At the telomere it appears that this filament bends back on itself and courses back through the length of the chromatid in such a way that there appear to be two such filaments loosely twined about one another (Fig. 3).

Around each of these segments of about 1200 Å there appear to be other filaments of various sizes ranging from about 100 Å through about 600 Å thickness. These filaments have moderate electron density, and at least some of them appear in turn to be surrounded by 30-50 Å thick filaments which have relatively great electron density.

Secondary constrictions and satellites have been clearly recognized as such in some electron micrographs, but too few have been seen to permit statements as to the precise nature of their structure.

Although these results are to be regarded as preliminary, they are based on chromosomes fixed and/or dried in acetic acid, ethanol, methanol, formaldehyde, glutaraldehyde, chromium trioxide, lanthanum nitrate, potassium molybdate and phosphotungstic acid.

Chromosomes in cells treated with hypotonic solutions followed by fixation with acetic acid and squashing fail to reveal recognizable units of structure. Instead, such chromosomes are seen as amorphous densities overlain by clumps of spherules, as are similarly prepared chromosomes in Fig. 9 of Barnicot and Huxley<sup>4</sup>. Some of the other fixatives and drying solutions have yielded results which are compatible with half chromatids composed of a hierarchy of pairings of smaller into larger and larger fibres as reported by Osgood<sup>5</sup> and by Cole and Langley<sup>6</sup>. However, numerous preparations which appear to be in a better state of preservation of structure show distinct patterns of smaller coils winding around the larger coils as in Fig. 3.

Investigations are now being made to construct complete models of specific chromosomes and to compare chemically, enzymatically, and microscopically induced dissociations of structure from otherwise intact chromosomes of diploid human cells.

## GENETICS

### Inbreeding and Genetic Loads in Irradiated Experimental Populations of *Drosophila melanogaster*

Morton, Crow and Muller<sup>1</sup> suggested that measurements of the inbreeding depression can be used to estimate the magnitude of the genetic loads which populations carry as well as to differentiate between the mutational and balanced components of such loads. Several studies designed to investigate this problem have been done in *Drosophila*<sup>2-4</sup> and in *Tribolium*<sup>5</sup>. The validity of the technique proposed by Morton, Crow and Muller has been questioned (see Levene<sup>6</sup> and Dobzhansky<sup>7</sup> for references). Inbreeding investigations, nevertheless, remain useful to the examination of genetic loads in populations, although the possibilities of discrimination between the mutational and balanced components have become remote. This communication summarizes the results obtained from investigations aimed at comparing the magnitudes of the genetic loads in experimental populations of *Drosophila melanogaster*. These populations have been exposed to X-irradiation (to the males) for a number of generations and then maintained without further irradiation for varying periods of time. Their radiation histories are outlined in Table 1.

The populations (except the control) had been subjected to a cumulative X-radiation exposure of 120,000 r, although at different rates. The egg-adult viability in these populations, after the initial rise for 3-4 generations following the cessation of the irradiation, has remained at a level between 70 and 75 per cent, below the level in the control population (87-90 per cent). This situation has persisted for more than 57 generations in VI-ER-20, 47 generations in LV-ER-80 and 35 generations in II-EGR-60.

The experiments investigating the effects of inbreeding on viability were carried out over a period of four consecutive contemporaneous generations, 70-73 in the control, 46-49 in VI-ER-20, 36-39 in IV-ER-30 and 23-26 in II-EGR-60. In all populations except the control, these represent the number of generations of relaxation from irradiation. The technique adopted was the same as that used by Malogolowkin *et al.*<sup>4</sup>. A total of 140 single-pair matings were set up per population. From each of the single-pair progenies, virgin females and males were collected and three types of crosses were set up as follows: (1) unrelated—between groups of 10 females from one culture and 10 males from a different

Table 1. CHARACTERISTICS OF THE EXPERIMENTAL POPULATIONS

Population	Treatment	Started
C-1	Control, no radiation	Sept., 1962
VI-ER-20	Males received 6,000 r. per generation for 20 generations	July, 1963
IV-ER-30	Males received 4,000 r. per generation for 30 generations	Dec., 1963
II-EGR-60	Males received 2,000 r. per generation for 60 generations	June, 1964

culture; (2) brother-sister matings—between groups of 10 females and 10 males from the same culture; (3) half-sib matings—a single male was crossed to a female from one culture and two days later the same male was crossed to a female from a different culture, and from the progenies groups of 10 females and males were taken and intercrossed. The inbreeding coefficients in the three kinds of matings are respectively  $F = 0$ , 0.25 and 0.125.

The egg-adult viability was studied in the progenies of the foregoing three types of mating. The flies were placed in 8-in. glass vials with spoons containing cornmeal-molasses-agar medium darkened with an admixture of charcoal for easy visibility of the eggs. Two samples of 50 eggs each were taken from each group of parents and were allowed to develop (in regular half-pint culture bottles containing cream of wheat-molasses medium) at 25° C. Complete counts of the adults hatching in the cultures were made.

The numbers of cultures with different percentages of survival from egg to adult stage are summarized in Table 2. It is obvious that the viability in the irradiated populations is lower than in the control. More interesting, however, is the distribution of the viabilities over a short range (and hence small variance). This is not unexpected, since all the populations were maintained under conditions of relaxed natural selection (for details, see Sankaranarayanan<sup>10,11</sup>). The *Drosophila* populations utilized for inbreeding studies so far were obtained either from Nature<sup>1-4</sup> or from population cages<sup>5,6</sup>, where natural selection is presumably more intense.

The mean viabilities observed on the inbred and outbred progenies are shown in Table 3. As expected, the outbred progenies ( $F = 0$ ) are the most viable, followed by the progenies of half-sib matings ( $F = 0.125$ ), and full-sib matings ( $F = 0.25$ ). In the control, the reduction in the viability due to inbreeding is relatively small. In the other three populations the inbreeding depression is greater, but not as great as observed in the studies on natural populations of *D. pseudo-obscura*<sup>1,2</sup> and *D. willistoni*<sup>3</sup>. In addition, the relative reduction in viability due to inbreeding is of the same order of magnitude in spite of the fact that these populations have been relaxed from irradiation for different numbers of generations. These data compare very well with those obtained by Torroja<sup>4,6</sup> for experimental populations of *D. pseudo-obscura*.

The  $A$  and  $B$  statistics and the  $B/A$  ratios and their standard errors are also presented in Table 3. These values have been calculated from the data following the method of Malogolowkin *et al.*<sup>4</sup>. The  $A$  value is a measure of the mortality in outbred progenies ( $F = 0$ ) and this mortality is due to a combination of genetic and environmental causes. The  $B$  value measures the additional mortality due to complete inbreeding.

Table 2. NUMBERS OF CULTURES WITH DIFFERENT PERCENTAGES OF SURVIVAL FROM EGG TO ADULT STAGE

Table 3. PERCENTAGES OF EGGS DEVELOPING TO THE ADULT STAGE IN OUTBRED AND INBRED PROGENIES AND ESTIMATES OF  $A$ ,  $B$  AND  $B/A$  VALUES

		C-1	VI-NR-20	IV-NR-30	II-EGR-60
Max to adult viability					
$F = 0$		87.23 ± 0.26	74.18 ± 0.22	71.52 ± 0.28	71.81 ± 0.20
$F = 0.125$		85.00 ± 0.24	69.56 ± 0.20	66.03 ± 0.46	66.04 ± 0.20
$F = 0.25$		83.42 ± 0.20	64.07 ± 0.48	60.81 ± 0.42	59.66 ± 0.42
$A$		0.1870 ± 0.003	0.2970 ± 0.004	0.3263 ± 0.004	0.3287 ± 0.004
$B$		0.1810 ± 0.015	0.5720 ± 0.033	0.6921 ± 0.031	0.7165 ± 0.022
$B/A$		1.22 ± 0.13	1.92 ± 0.13	2.06 ± 0.11	2.12 ± 0.11

The  $A$  value is small in the control and is larger in the populations with radiation histories. The  $B$  value is, again, small in the control and is much larger in the other populations. Among the irradiated populations VI-NR-20, which had the greatest number of generations of relaxation from irradiation (and hence was exposed to the action of normalizing natural selection for a greater length of time), has the lowest  $B$  value, followed by IV-NR-30 and II-EGR-60. The differences, although not significant, are in the expected direction. It is interesting to point out that the  $B$  values are somewhat smaller than those calculated for natural populations<sup>4,6</sup>.

The  $B/A$  ratios are small, ranging from 1.32 for the control to about 2 in the other populations. This does not necessarily mean that the genetic loads in these populations are predominantly balanced. This is unlikely in the radiated populations which have been under induced mutation pressure for several generations and then relaxed without irradiation for a period between 30 and 57 generations. It is possible that under the selection conditions in which these populations were maintained, numerous induced mutants affecting viability and which are semidominant still persist. The consequence of this will be an inflated  $A$  value resulting in a small  $B/A$ . This, coupled with the questionable validity of the  $B/A$  ratio to determine the genetic structure of the populations, makes the utility of the  $B/A$  statistic quite dubious. Dobzhansky *et al.*<sup>3</sup>, Malogolowkin *et al.*<sup>4</sup> and Levene *et al.*<sup>7</sup> came to the same conclusion.

$A$ ,  $B$  and  $B/A$  values calculated taking into consideration only two of the three examined viability values are not significantly different from those obtained using all three viability values. This indicates that there are no significant departures from linearity within the range of the  $F$ 's studied.

This work was done under contract AT(30-1)3096, U.S. Atomic Energy Commission. I thank Prof. Th. Dobzhansky and Prof. Howard Levene for their advice, Mr. Wyatt W. Anderson for programming and processing the data using the control data 160-A computer, and Prof. H. Keffler Hartline for permitting the use of the computer, and Mrs. Kokila Sankaranarayanan for her assistance.

## PSYCHIATRY

### Object-naming by Dysphasic Patients

In previous communications<sup>1,2</sup> two of us reported that with normal subjects the time taken to name an object is inversely proportional to the logarithm of the frequency of the name-word in the language, as estimated by a standard word-count<sup>3</sup>. These experiments were originally undertaken to clarify the incapacity to name objects shown by individuals who have suffered some forms of brain injury, and the study has accordingly now been extended to subjects of this kind. The technique has necessarily been simplified and now comprises manual display of cards bearing the 26 pictures of objects origin-

ally used, and timing with a stop-watch (1/100 sec) in place of the optical projection and timing by voice-key and pen-recorder in the experiment previously reported.

The subjects were all men with penetrating gunshot head-wounds, the majority incurred in the Normandy campaign of 1944. Their ages ranged from 37 to 61, with a mean age of 44.5 years. The total number of cases tested was 102, but of these, 24 had bilateral lesions and these have been excluded for the present purpose as have those 4 who were not unquestionably right-handed. Fig. 1 shows the frequency-latency relationship for the remainder divided into the relevant lesion groups, having similar mean ages and verbal intelligence quotients. Also shown are results for the university group used in the previous experiment together with those for a hospital control group (patients of age and verbal level similar to the brain injured but with no ascertained neurological or psychiatric disorder). In the case of the dysphasics those results have been rejected in which, following presentation of the stimulus, two or more verbal interjections were made before the correct response. Once such an individual becomes involved in circumlocutory speech; the further period thus expended is somewhat random in amount.

With regard to Fig. 1, a linear relationship was found to subsist between mean latencies for the 26 objects and the logarithm of their frequencies, the coefficients of correlation ranging from  $-0.80$  to  $-0.87$  ( $P < 0.001$ ). Analysis of variance confirmed the goodness of fit of these five linear regressions at  $P < 0.001$ . Analysis of variance showed the latencies for all sub-groups to differ from each other at  $P < 0.01$  to  $P < 0.001$ , with the exception of the university subjects and the hospital control group, where the difference failed to reach significance.

A comparison of regression coefficients showed that the slopes of the three brain-damaged groups differed significantly from the hospital controls ( $P < 0.01$  to  $P < 0.001$ ), and the dysphasics versus left-hemisphere group without dysphasia at  $P < 0.05$ . The difference between slopes for the dysphasics as compared with the right-sided group, and the left- and right-hemisphere groups without dysphasia failed to reach significance, as did the slopes for the university subjects and hospital controls.

We draw the following conclusions from these results.

(1) Lower verbal intelligence and greater age bring about a trend toward increased latency compared with findings for a university population. (2) Any form of brain lesion

Fig. 1. Response-latency in naming objects versus  $\log_{10}$  frequency of occurrence of the name in English for brain-damaged patients with and without dysphasia, hospital controls and university subjects. O, Dysphasia; ●, right hemisphere not dysphasic; Δ, left hemisphere not dysphasic; ▲, hospital control group; □, university subjects

Fig. 2. Percentage of subjects correctly naming objects versus  $\log_{10}$  frequency of occurrence of the name in English. O, Dysphasia; ●, right hemisphere not dysphasic; Δ, left hemisphere not dysphasic; ▲, hospital control group; □, university subjects

results in a further and significant increase. (3) Right-sided lesions exercise a larger effect in this connexion than those left-sided ones which produce no speech disorder. (4) Lesions productive of speech-disorder, as assessed by clinical test, show the greatest increase in the time required to name objects.

Attention has been directed by Paterson and Zangwill<sup>4</sup>, and Milner<sup>5</sup> (reviewed by Piercy<sup>6</sup>) to the disturbing effects of some right-hemisphere lesions on visual perception. This could account for the differences between right and left non-dysphasic patients, but further analysis of the localization data, now in progress, is required to clarify this.

Fig. 2 shows the results, for the same groups, in terms of percentage correct naming against log frequency of the word-names. This affords clear evidence that the detection of slight, or residual, speech-disorder by a naming test requires the use of objects (or pictures of them) which are of a certain order of rarity, as assessed by their name-words. With objects the names of which have a frequency of above 10 per million, there is virtually no difference in the number correctly named (98 versus 100 per cent), while above 80 per million, in this case, no failures at all occur (even if such a difference may appear with the more refined technique of latency-measurement). A marked difference in correct responses appears only with objects the names of which have a frequency below  $10^{-5}$ .

We thank Dr. W. Ritchie Russell for the facilities granted us, and for permission to study patients under his care.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, September 13—Friday, September 17

INSTITUTE OF ELECTRONICAL ENGINEERS (at Savoy Place, London, W.C.2)  
—International Conference on "The Microwave Behaviour of Ferrimagnetics and Plasmas".

Tuesday, September 14

UNIVERSITY OF LONDON (in the Meyershall Lecture Theatre, Westminster Medical School, Horseferry Road, London, S.W.1), at 5.15 p.m.—Prof. D. J. Hanahan (University of Washington): "Observations on Lipid-Protein Involvement in Human Erythrocyte Membranes".\*

Wednesday, September 15

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. J. W. Pearson and Mr. K. R. Williams: "Hydrocarbon Fuel Cells".

Thursday, September 16

OIL AND COLOUR CHEMISTS' ASSOCIATION (in the Small Physics Lecture Theatre, Imperial College of Science and Technology, London, S.W.7), at 7 p.m.—Mr. G. R. Pye: "The Decoration of Plastics".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

POST-DOCTORAL FELLOW (cell biologist or biochemist) IN THE DEPARTMENT OF ZOOLOGY, to work with Dr. L. G. H. Bell on problems associated with cell surface function—The Deputy Secretary, The University, Southampton (September 14).

RESEARCH FELLOW (preferably with a special interest in the solution of partial differential equations) IN NUMERICAL ANALYSIS; an ASSOCIATE RESEARCH FELLOW to work in the field of industrial statistics or operational research; and a RESEARCH ASSISTANT to work, under guidance, on the analysis and appraisal of technical literature with particular reference to process control—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham, 4, quoting Ref. 432/2 (September 14).

ASSISTANT LECTURER IN ZOOLOGY—The Registrar, The University, Manchester, 13, quoting Ref. 165/65/NA (September 15).

POST-DOCTORAL RESEARCH ASSISTANT (S.R.C.) for research on low-temperature organic chemistry—The Registrar, The University, Bristol, 2 (September 15).

TECHNICIANS IN THE DEPARTMENT OF BOTANY for general duties and to assist with research in plant physiology—The Registrar, University College of Wales, Aberystwyth (September 15).

RESEARCH-MICROSCOPE TECHNICIAN (preferably with previous experience in electron-microscopy) IN THE DEPARTMENT OF APPLIED PHYSICS, to assist with the operation and maintenance (day-to-day only) of the Department's JEOL-7 electron-microscope—The Secretary, Welsh College of Advanced Technology, Cathays Park, Cardiff (September 15).

DEMONSTRATOR OR TEACHING FELLOW IN THE DEPARTMENT OF PHYSICAL CHEMISTRY—The Registrar, The University, Leeds, 2 (September 20).

RESEARCH FELLOW (graduate in medical or biological science and preferably some postgraduate training in laboratory methods) IN THE DEPARTMENT OF MATERIA MEDICA AND THERAPEUTICS, to work as a member of an established research team investigating the hormonal disturbances associated with thyroid disease—The Secretary, The University, Aberdeen (September 20).

LECTURER (with a good honours degree, some experience of teaching and/or research, and preferably special qualifications or experience in fluid mechanics and gas turbine engineering) IN MECHANICAL ENGINEERING—The Registrar, King's College (University of London), Strand, London, W.C.2 (September 21).

SENIOR LECTURER (honours graduate with good teaching experience) IN CROP HUSBANDRY—The Principal, Essex Institute of Agriculture, Writtle, Chelmsford, Essex (September 23).

ASSISTANT IN APPLIED PSYCHOLOGY—The Secretary, University College, Cork, Republic of Ireland (September 24).

SCIENTIFIC OFFICER (with a first- or good second-class honours degree in geology and preferably a knowledge of X-ray crystallography) IN THE DEPARTMENT OF PEDOLOGY, for work concerned with optical, mineralogical and petrological studies in soils—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (September 24).

D.S.I.R. SENIOR RESEARCH ASSISTANT to work with Dr. J. B. Horderby on a programme of structure determination in liquid metals and alloys using neutron techniques—The Registrar, The University, Sheffield, 10 (September 25).

DEMONSTRATOR IN AGRICULTURE (Agronomy) to assist with experimental work and for general University duties—The Registrar, The University, Leeds, 2 (September 27).

SENIOR LECTURER or LECTURER (preferably with wide experience of West African conditions) IN THE DEPARTMENT OF AGRICULTURAL CHEMISTRY AND SOILS, University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 27).

POST-DOCTORAL FELLOW (with experience in plasma physics, microwave techniques or electro-magnetic theory and use of a computer) in a plasma physics group which is studying the scattering of microwaves by various plasma configurations—The Registrar, University College of Wales, Aberystwyth (September 28).

CHAIR OF NUCLEAR PHYSICS—The Secretary, University of Lancaster, Bailrigg House, Lancaster (September 30).

CHAIR OF PHARMACEUTICAL TECHNOLOGY—The Registrar, University of Strathclyde, Glasgow, C.1 (September 30).

LECTURER IN CIVIL ENGINEERING at the University of Adelaide, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

PROFESSOR OF ZOOLOGY (Pleasantburg); and a SENIOR LECTURER IN ZOOLOGY (Pleasantburg), University of Natal, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, September 30).

READER or SENIOR LECTURER (medical) IN THE DEPARTMENT OF PHARMACOLOGY—The Registrar, The University, Manchester 13, quoting Ref. 171/65 (September 30).

RESEARCH ASSISTANT (with a Ph.D. degree in chemistry) to Dr. J. S. Whitehurst, to work on steroids—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devon (September 30).

RESEARCH STUDENT (suitably qualified electronic or electrical engineer or physicist interested in research in the field of digital frequency modulation) IN THE DEPARTMENT OF ELECTRONICS—Prof. G. D. Sims, University of Southampton, Southampton (September 30).

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER (with an honours degree and basic training in microbiology, together with research experience and preferably a Ph.D.) to carry out fundamental research on food micro-organisms particularly the bacteria associated with the spoilage of eggs and egg products—The Secretary, Low Temperature Research Station, A.R.C., Downing Street, Cambridge (September 30).

SENIOR LECTURER or LECTURER (with extensive experience in digital computing) IN THE FIELD OF COMPUTING at Monash University—The Registrar, Monash University, P.O. Box 92, Clayton, Victoria, Australia; or The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

SENIOR RESEARCH OFFICER (Dental) (with previous experience in research and preferably a higher degree) IN THE INSTITUTE OF DENTAL RESEARCH—The Secretary, United Dental Hospital of Sydney, 2 Chalmers Street, Sydney, New South Wales, Australia (September 30).

BIOCHEMIST (Senior Research Officer) to organize and develop a new Biochemistry Laboratory in the Clinical Sciences Building, Royal Melbourne Hospital, IN THE UNIVERSITY DEPARTMENT OF PSYCHIATRY—Prof. B. M. Davies, Department of Psychiatry, University of Melbourne, Parkville, M.2, Victoria, Australia (October 1).

SENIOR LECTURER (with special interest in physical oceanography, including dynamic oceanography and/or marine geology) IN OCEANOGRAPHY; and a LECTURER (preferably with a special interest in oceanography) IN BIOCHEMISTRY—The Registrar, University College of Swansea, Singleton Park, Swansea (October 1).

BIOCHEMIST or CHEMIST (Ph.D. or equivalent experience) IN THE DEPARTMENT OF BIOCHEMISTRY to participate in a research programme on naturally occurring sulphate esters—Prof. K. S. Dodgson, Department of Biochemistry, University College of South Wales and Monmouthshire, St. Andrew's Place, Cardiff (October 2).

LECTURER (with qualifications and a special interest in the teaching of mathematics or chemistry) IN EDUCATION—The Registrar, The University, Sheffield (October 2).

COMPUTER MANAGER (with previous experience with large electronic computers) for the KDF9 installation in the Electronic Computing Laboratory—The Registrar, The University, Leeds, 2 (October 3).

RESEARCH FELLOW (graduate in physics or physical chemistry) IN PHYSICAL CHEMISTRY to experiment on the electronic properties of organic vapours—The Registrar, University of Queensland, Brisbane, Australia (October 14).

ASSISTANT EXPERIMENTAL OFFICER (graduate in a biological science (pure or applied) with an interest in field work) IN THE NEMATOLOGY DEPARTMENT to assist in work on nematodes injurious to cereals and their control—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1063/80 (October 15).

SENIOR LECTURER IN ELECTROMAGNETISM IN THE DEPARTMENT OF ELECTRONIC AND ELECTRICAL ENGINEERING—The Assistant Registrar (Science), The University of Birmingham, Birmingham 15 (October 15).

CHAIR OF BIOLOGY (in the field of Plant Physiology) AT THE UNIVERSITY OF SYDNEY, AUSTRALIA—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 25).

CHAIR OF THERMODYNAMICS AND FLUID MECHANICS (a second chair in the Department of Mechanical Engineering)—The Secretary, The Queen's University of Belfast, Belfast, Northern Ireland (October 30).

LECTURER (with a Ph.D. degree or equivalent qualifications) IN THE SCHOOL OF CHEMISTRY, University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 30).

ARNOLD YILDHAM and MARY RAINE MEDICAL RESEARCH FELLOWS (medical or science graduates) in arteriosclerosis and allied diseases in the Faculty of Medicine, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 31).

CHAIR OF MATHEMATICS (R.A.A.F. Academy), University of Melbourne, Australia—The Registrar, University of Melbourne, Melbourne, Australia; or The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (November 1).

ASSISTANT FORENSIC SCIENTIST (with a B.Sc. degree including physics or chemistry or botany (or similar professional qualification) with some research experience, and preferably a knowledge of photography) with the British South Africa Police in Salisbury, Rhodesia—The Police Recruiting Officer, Rhodesia House, Strand, London, W.C.2.

BIOLOGY GRADUATES to train as Cyto-technologists IN THE CYTOLOGY SECTION OF THE PATHOLOGY DEPARTMENT—The Hospital Secretary, Christie Hospital and Holt Radium Institute, Manchester, 20.

ENTOMOLOGIST (national of the United Kingdom or the Republic of Ireland, with a degree in natural science, preferably with second-class honours, of which zoology should be a principal subject; some postgraduate experience is desirable) in Malawi, to supervise phytosanitary services including exports and imports; to carry out systematic work in the museum; to identify pests and advise on control measures; and to carry out some entomological research—The Appointments Officer, Ministry of Overseas Development, Room 301, Strand House, Stag Place, London, S.W.1, quoting Ref. RO 218/184/06.

GRADUATE RESEARCH OFFICER (preferably with experience in medical statistics, biometry or genetics) IN STATISTICS IN THE OXFORD RECORD LINKAGE STUDY AND UNIT OF CLINICAL EPIDEMIOLOGY—The Medical Director, Oxford Record Linkage Study, Nuffield Department of Clinical Medicine, Radcliffe Infirmary, Oxford.

LABORATORY TECHNICIANS, Grades III and IV, in the DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY for work connected with chemistry, biochemistry, or physiology—The Assistant Bursar (Personnel), University of Reading, Reading, Berkshire.

LECTURER IN BOTANY; a LECTURER IN CHEMISTRY; and a LECTURER IN PHYSICS at the University of Basutoland, Buthaburane Protectorate and Swaziland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

LECTURER (with a special interest in spectroscopy, and preferably a research degree and able to teach physical chemistry to honours degree standard) IN PHYSICAL CHEMISTRY—The Registrar, Regional College of Technology, Leicester.

MICROBIOLOGISTS and/or ORGANIC CHEMISTS to study antibiotic-producing and similar fermentations in an intensive programme combining academic

interest with practical importance—Dr. J. D. Pu'Lock, Department of Chemistry, The University, Manchester, 13.

POST-DOCTORAL FELLOW IN THE CHEMICAL LABORATORY for work on synthetic organic chemistry—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex.

PRINCIPAL BIOCHEMIST to have responsibility in association with the Consultant Chemical Pathologist for the chemical pathology services at Paddington General and St. Charles Hospitals—The Group Secretary, Paddington General Hospital, London, W.9.

PROFESSOR OF MECHANICAL ENGINEERING—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 42/AF.

RESEARCH ASSISTANT IN THE DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY to work on problems relating to egg shell structure and strength—The Assistant Bursar (Personnel), University of Reading, Reading, Berkshire.

RESEARCH FELLOW (chemist or physicist with research experience) for work on high pressure chemistry—Dr. B. S. Bradley, School of Chemistry, The University, Leeds, 2.

RESEARCH OFFICER (Biologist) (national of the United Kingdom or the Republic of Ireland, with a first- or second-class honours degree in biology, and preferably postgraduate experience, particularly in pest control work, ecology or physiology) with the East African Common Services Organization, to study all aspects of the control of aquatic snails which are the intermediate hosts of trematode diseases, particularly by chemicals—The Appointments Officer, Ministry of Overseas Development, Room 301, Mland House, Stag Place, London, S.W.1, quoting Ref. RO 213/514/06.

SCIENCE GRADUATE FOR A CLINICAL INVESTIGATION UNIT, to work in medical laboratory research in association with the Department of Therapeutics, University of St. Andrews—The Medical Superintendent, Maryfield Hospital, Dundee.

SENIOR RESEARCH ASSOCIATE (Post-Doctoral) IN THE SCHOOL OF CHEMICAL SCIENCES for work in the preparation and spectroscopic study of diamagnetic aromatic molecules or co-ordination compounds—Prof. S. F. Mason, School of Chemical Sciences, University of East Anglia, Wilberforce Road, Norwich, NOR 77H.

SENIOR RESEARCH FELLOW (suitably qualified graduate) IN THE DEPARTMENT OF PRODUCTION AND INDUSTRIAL ADMINISTRATION to be concerned with the development of a high precision 3-co-ordinate measuring machine incorporating an interferometric laser system—The Registrar, The College of Aeronautics, Cranfield, Bedford.

SENIOR TECHNICIAN (with experience in the use of an electron microscope, preferably Siemens Elmiskop I, and familiarity with biological preparatory methods) for electron microscopy in the HISTOLOGY DEPARTMENT—The Registrar, The University, Liverpool 3, quoting Ref. 242/N.

SCIENTIFIC GLASSBLOWER (fully trained and experienced)—Dr. A. J. Croft, Garendon Laboratory, University of Oxford.

TECHNICAL ASSISTANT (preferably with some knowledge of biology or histological techniques) in the ELECTRON MICROSCOPE UNIT—Prof. H. J. J. Blackwood, Royal Dental Hospital, 32 Leicester Square, London, W.C.2.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

Society for the Promotion of Nature Reserves. *Advances in British Nature Conservation*. By B. M. Nicholson. (Preprint from the Society's Handbook for 1965.) Pp. 16. (London: Society for the Promotion of Nature Reserves, 1964.)

Bulletin of the British Museum (Natural History). Entomology. Vol. 17, No. 1: Delphacidae from Australia and New Zealand (Homoptera: Fulgoroidea). By R. G. Fennah. Pp. 1-59. (London: British Museum (Natural History), 1965.) 22s. 6d.

Technical Composition: a Service to Science. Pp. 15. (London: Spottiswoode, Ballantyne and Co., Ltd., 1965.)

Ministry of Technology. *Ergonomics for Industry No. 8: Thermal Comfort in Industry*. By Dr. R. H. Fox. Pp. 20. (London: H.M. Stationery Office, 1965. Obtainable from Warren Spring Laboratory, Stevenage, Herts.) Gratis.

The National Council for the Unmarried Mother and her Child. *Annual Report April 1964-March 1965*. Pp. 52. (London: The National Council for the Unmarried Mother and her Child, 1965.)

Patent Office. *Periodical Publications in the Patent Office Library: List of Current Titles*. Third edition. Pp. v+436. (London: H.M. Stationery Office, 1965.) 28s. net.

British Museum (Natural History). *Instructions for Collectors*. No. 10: *Plants*. Sixth edition. Pp. 72. (London: British Museum (Natural History), 1965.) 3s.

The Grower's Digest of Current Research, Vol. 2, covering Publications Issued Between July 1963 and July 1964. Compiled by R. T. Peard. Pp. 88. (London: Grower Publications, Ltd., 1965.) 20s. net.

Ministry of Overseas Development. *Report of the Anti-Locust Research Centre, 1st April 1961 to 31st December 1964*. Pp. v+49+8 plates. (London: H.M. Stationery Office, 1965.) 5s. 6d. net.

### Other Countries

The Carlsberg Foundation's Oceanographical Expedition Round the World 1928-30 and previous "Dana" Expeditions. "Dana" Report No. 65: *Ostracoda-Mysidocopa*. Part II: *Cypridiniformes-Ruditiermatidae, Sarsellidae and Asteroidea*. By Erik M. Poulsen. Pp. 484. (Copenhagen: Andr. Fred. Hest and Son, 1965.) 145 D kr.

Deutscher Wetterdienst. *Deutsches Meteorologisches Jahrbuch 1961*. Pp. xxxv+221. (Offenbach, a.M.: Deutscher Wetterdienst, 1963.)

National Museum of Canada. Bulletin No. 197 (Anthropological Series No. 65). *Songs of the Newfoundland Outports*. Collected and edited by Kenneth Peacock. Vol. 1: Pp. xxv+1-234. Vol. 2: Pp. xli+325-644. Vol. 3: Pp. xli+645-1036. (Ottawa: Queen's Printer, 1965.) 15 dollars the three volumes.

Records of the Dominion Museum, Wellington. Vol. 5, No. 11 (7 April 1965): *New Sea-Occumbers (Holothuroidea) from New Zealand Waters*. By David L. Paxon. Pp. 75-82. Vol. 5, No. 12 (7 April 1965): *The Mesocostal Groove in Ziphidae, with special reference to its closure by Ossification in Mesopoda-Osteoda*. By Charles McOmnn. Pp. 82-88. (Wellington: Dominion Museum, 1965.)

Estacion Experimental del Zaidin, Granada. *Memoria (1963-1964)*, Número 2. Pp. H+61. (Granada: Estacion Experimental del Zaidin, 1965.)

World Health Organization. *Technical Report Series, No. 209: Specifications for the Identity and Purity of Food Additives and Their Toxicological Evaluation*. Food Colours and some Antimicrobials and Anti-oxidants—Eighth Report of the Joint FAO/WHO expert Committee on Food Additives. Pp. 25. (Geneva: World Health Organization; London: H.M. Stationery Office, 1965.) 2 Sw. francs; 2s. 6d.; 0.60 dollars.

Smithsonian Contributions to Astrophysics. Vol. 8, No. 5: *On the Luminous Efficiency of Meteors*. By Franco Vernani. Pp. 141-173. 20 cents. Vol. 8, No. 7: *Meteor Geomagnetic Effects*. By Sydney Chapman and Attila A. Aschour. Pp. 181-197. 20 cents. (Washington, D.C.: Government Printing Office, 1965.)

Annuaire 1965 du Génie Atomique. (Publié par l'Association des Ingénieurs en Génie Atomique.) Pp. 127. (Paris: l'Association des Ingénieurs en Génie Atomique, 1965.)

Bulletin of the Museum of Comparative Zoology, Harvard University. Vol. 123, No. 1: *Gular Musculature in Delphinids*. By Barbara Lawrence and William M. Schvill. Pp. 1-65. Vol. 123, No. 2: *A Revision of the Genus Rhabdophrys in the Americas (Hymenoptera, Bethyridae)*. By Howard M. Evans. Pp. 67-151+7 plates. Vol. 123, No. 3: *Rhabdophrys serpentina, a New Rhabdophrys Pterygophorid from the Texas Lower Permian*. By John Newland Chase. Pp. 153-223+5 plates. (Cambridge, Mass.: Museum of Comparative Zoology, Harvard University, 1965.)

The Use of Citation Data in Writing the History of Science. Pp. v+76. (Philadelphia: Institute for Scientific Information, 1964.)

The Weizmann Institute of Science. *Scientific Activities 1964*. Pp. iii+284. (Rehovoth, Israel: The Weizmann Institute of Science, 1965.)

Food and Agriculture Organization of the United Nations. *FAO Agricultural Development Paper No. 80: Methods of Farm Management Investigations for Improving Farm Productivity*. Prepared by W. Y. Yang. Revised edition. Pp. xli+253. (Rome: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1965.) 17s. 6d.; \$5.50 dollars.

Australia: Commonwealth Scientific and Industrial Research Organization. *The Radiophysics Laboratory, Sydney, 1963-1964*. Pp. 29. (Sydney: The Radiophysics Laboratory, C.S.I.R.O., 1965.)

Museum of Comparative Zoology, Harvard University. *Breviora*. No. 218 (May 7, 1965): *New Frogs of the Genus *Craugastor* (Anura) from the Solomon Islands*. By Walter O. Brown. Pp. 16 (2 plates). No. 219 (May 7, 1965): *The Early Evolution of the Heliconiinae*. By H. Barrclough Fell. Pp. 17. No. 220 (May 7, 1965): *A New Species of *Eleutherodactylus* from Guadeloupe, West Indies*. By John D. Lynch. Pp. 7. No. 221 (May 7, 1965): *New Melanesian Ants (Hymenoptera: Formicidae) of Zoogeographic Significance*. By Robert W. Taylor. Pp. 11. No. 222 (May 23, 1965): *The Genus *Leptotyphlops* in the West Indies, with Description of a New Species from Hispaniola (Serpentes, Leptotyphlopidae)*. By Richard Thomas. Pp. 12. No. 223 (May 23, 1965): *A New Subspecies of *Crotalus ophiomaculatus* (Serpentes: Colubridae) from the Island of Grenada*. By Allen H. Greer. Pp. 6. (Cambridge, Mass.: Museum of Comparative Zoology, Harvard University, 1965.)

The Yearbook of the National Institute of Sciences of India 1964. Pp. 133. (New Delhi: National Institute of Sciences of India, 1965.)

Unesco. *World Guide to Science Information and Documentation Services*. Pp. 211. (Paris: United Nations Educational, Scientific and Cultural Organization, 1965.)

Canada: Department of Mines and Technical Surveys. *Geological Survey of Canada. Bulletin 103: Late Upper Jurassic and Early Lower Cretaceous Fossil Zones of the Canadian Western Cordillera*. British Columbia. Pp. x+70+22 plates. 4.50 dollars. Paper 65-9: *Salt Beds, South-western Ontario*. By B. V. Sanford. Pp. 7. 75 cents. (Ottawa: Queen's Printer, 1965.)

Food and Agriculture Organization of the United Nations. *FAO Agricultural Studies No. 64: Vascular Plants and the Liver Fluke*. By R. L. Taylor. Pp. xxi+224. (Rome: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1964.) 15s.; 3 dollars.

Australia: Commonwealth Scientific and Industrial Research Organization. *CSIRO Divisions and Sections, 1965*. Pp. 23. (East Melbourne: Commonwealth Scientific and Industrial Research Organization, 1965.)

New Zealand Forest Service: Forest Research Institute. *Forestry Research Notes*. No. 39: *The Lowry Humpy-Cell Process for Preservation of Radiata Pine Timber—Treating and Kiln-Drying Trials*. By J. A. Kilmunth. Pp. 15. (Wellington: Government Printer, 1965.)

Zoology Publications from Victoria University of Wellington. No. 88 (21 May 1965): *Zooplankton of Wellington Harbour, New Zealand*. By R. G. Wear. Pp. 31. (Wellington: Government Printer, 1965.)

British Guiana. *Report on the Geological Survey Department for the year 1962*. Pp. 82+2 plates. (Georgetown: Geological Survey Department, 1964.)

Organization for Economic Co-operation and Development. *European Nuclear Energy Agency. Second Report on the Activities of the Eurochemic Company, 1962-1964*. (European Company for the Chemical Processing of Irradiated Fuels) Pp. viii+533. (Paris: Organization for Economic Co-operation and Development, European Nuclear Energy Agency, 1965.)

Canada: Department of Mines and Technical Surveys. *Geological Survey of Canada. Map 6-1965: Oil and Gas Fields, South-Western Ontario*. (Ottawa: Director, Geological Survey of Canada, 1965.)

5th Inter-American Symposium on the Peaceful Application of Nuclear Energy. (Symposium sponsored by the Inter-American Nuclear Energy Commission and the Government of Chile, with the co-operation of the U.S. Atomic Energy Commission, at Valparaiso, Chile, March 9-13, 1964.) Pp. vii+260. (Washington, D.C.: Pan American Union, 1965.) 2.50 dollars.

Memories of the Mount Stromboli Observatory. No. 17: *Catalogue of Open Clusters South of -45° Declination*. By A. R. Hong. Pp. 17. (Osteria: The Australian National University, 1965.)

## THE PLIGHT OF LIBRARY SERVICES IN BRITAIN

IN his presidential address to the Library Association at Harrogate in May, Sir Frank Francis denied that at present Britain had any library system as such. He did, however, comment on such recent developments as the coming into force of the Public Libraries and Museums Act, with its provisions for a more comprehensive and far-reaching public library service and for establishing a Libraries Advisory Council, the creation in the Department of Education and Science of a national organization for scientific and technological information and the proposals of the Library Association for a national bibliographical advisory council and a national bibliographical centre. While Britain's libraries may present a sort of pattern, they have grown up in numerous ways and there is no formal relation between the various groups. Even such arrangements as exist are really only attempts to overcome obstacles to the supply of information caused by Britain's unorganized provision of libraries.

Sir Frank put his finger unerringly on the vital weakness, and it is this which needs to be tackled first. Indeed, unless we can advance considerably towards the development of a national system, it is unlikely that realistic and sound decisions regarding provision for the libraries of the universities and other institutions of higher learning will be taken when the Parry Committee reports. Again, sound as in principle is the creation of the new Office for Scientific and Technological Information, it represents a piecemeal approach which can endanger much more vital elements in a national system. The new organization is comparatively unimportant compared with the Patent Office Library and the new National Reference Library for Science and Invention which is to succeed it. From the scientific and technical point of view, the latter Library, which is the essential counterpart to the National Lending Library for Science and Technology at Boston Spa, is a first priority in any national system, but no Government has yet given the scheme the whole-hearted and urgent support that the national interest demands. While the new organization set up by the Department of Education and Science may in time provide much information which will be invaluable in formulating national policy in the whole field, its present importance is trivial compared with bringing into effective service the National Reference Library for Science and Invention.

It is in the light of this situation that the numerous proposals for developments in the field of libraries and information services are best appraised at the present time. Sir Frank Francis himself emphasizes that the biggest problems are centred in the learned libraries and in the adequacy of the library and information services at the highly specialized level. Since it is proposed, however, that the new National Reference Library for Science and Invention should form part of the British Museum, it was strange that Sir Frank made no reference to the delays in starting the new building or even to the urgency of establishing such a library on a much more adequate scale than even the Patent Office Library which it is to replace. Nor, in discussing the part that inter-library lending should play in Britain's library economy and the most satisfactory basis on which to plan such lending, did he consider the relation between the new National Reference Library for Science and Invention and

the National Lending Library for Science and Technology. Since the declared policy of the latter is to concentrate on literature of the past fifty years, there is an obvious gap if the needs of the inventor as well as of the historian of science or technology are to be served reasonably. This cannot be shrugged off merely by defending the sound practice of the British Museum Library that the visiting scholar should be assured that a very high proportion of his requirements can be met on the spot.

There is a difficulty here which must be met by considered policy and some reasonable arrangements regarding holdings of older scientific and technical literature, either for reference or for loan of the originals or of photo- or micro-copies. It is one of the problems which a national system can (and should) solve, and it is also one of those which the division of Government responsibility for information services between two Ministries, as has already been noted (*Nature*, 208, 968; 1965), may make more difficult. Sir Frank Francis admitted in his address that without the willing and disinterested co-operation of librarians and the institutions they served the Department of Education and Science would be unable to develop properly the new services of the British Museum, including this new department with its current scientific reference collection of one million volumes on open shelves, with relevant specialist advice and a staff of some 200. He said nothing, however, about the urgent need for action to provide the space which will enable the services to operate nor did he refer to the Ministry of Technology.

Meanwhile, the Library Association is itself concerned about the lack of adequate national planning to organize efficient access to the ever-increasing output of books, periodicals, reports and other documents, and besides its Committee on Scientific Library Services it has a Working Party of its Research Committee on National Reference Services which has issued a preliminary report, *Access to Information*\*. This report, which was discussed recently by Mr. L. Corbett in the *Library Association Record* for May (67, 151; 1965), outlines the proposals for a national bibliographical advisory council and a national bibliographical centre noted here. They are intended to meet the need for a national planning body for such services and for an organization which will provide points of entry into the service available.

At present nothing effective is being done to create a national plan, although the Library Association, the Association of Special Libraries and Information Bureaux (Aslib), the Department of Scientific and Industrial Research (until its dissolution) and the Royal Society have intermittently promoted the development of bibliographical and information services. Research into the development of library, bibliographical and information techniques is at present carried out by several bodies, as is to be seen, for example, in the survey of information needs of physicists and chemists undertaken in 1963-64 by Prof. B. H. Flowers on behalf of the Advisory Council on Scientific Policy and reported in the *Journal of Documentation* (21, 83; 1965). Akin to this is the survey of chemical publications made by Dr. R. S. Cahn for the Chemical Society of which an outline has been published

\* The Library Association. *Access to Information: a National Bibliographical Service*. Pp. 4. (London: The Library Association, 1965.)

in *Chemistry in Britain* for August (1, 358; 1965). Earlier in the year Prof. W. C. Overend opened a parallel discussion of this subject before the Society of Chemical Industry, and at the Library Association's annual conference at Harrogate in May, Mr. K. A. Mallaber, chairman of the Association's Library Research Committee, read what he believed to be the first paper on research read at the Association's annual conferences. Techniques and trends in the effective utilization of engineering information were discussed by Mr. B. E. Holm in a paper published in *Aslib Proceedings* (17, 124; 1965).

The Public Libraries and Museums Act, 1964, gives the Department of Education and Science general oversight of the public library service and it will be responsible for ensuring that workable schemes of inter-library co-operation exist. Besides participating in the co-ordination of effort and determining priorities, its responsibilities include establishment of the National Reference Library for Science and Invention and the National Lending Library for Science and Technology. It is intended that the new Office for Scientific and Technical Information shall bring together all the various growing points, including the needs of university libraries, and see how the various proposals can best be fused into a national policy for developing scientific library and information services. While the Office will promote new services wherever the need is proved, it will not seek to run such services unless no other suitable organization exists.

The new Office was set up after the preliminary report *Access to Information* was completed, but while the Working Party was aware of the proposals on which the new organization was based, it did not consider they offered a complete solution. Like the Heyworth Committee, which recommended a specific enquiry on this point, it saw a similar need for bibliographical organization in the social sciences and the humanities and suggested that duplication of effort could be avoided if the arrangements for scientific documentation served other subject fields as well. A national plan requires effective national machinery.

While the National Central Library is the recognized centre for inter-library lending of books it is still inadequate as a bibliographical information centre. Sir Frank Francis laid some stress on the differences in the needs of the scholar in the humanities as compared with the sciences or technology in this connexion. He thought it unlikely that a central lending library for the humanities would need to duplicate a large part of the holdings of the British Museum and other libraries. The Working Party suggests that to be effective the union catalogues of the National Central Library should include the holdings of major national, university and research libraries, irrespective of whether the material is or is not available for lending. No formal arrangements, however, exist to cover the immense reference potential of the British Museum and such national libraries as the Science Library, the Patent Office Library, apart from many of the smaller special libraries, a few university libraries and the public libraries, and even the *British National Bibliography* covers only a limited selection of Britain's published output.

While some of the services which are required under a national plan are thus in existence, they require extending and co-ordinating. To this end it is proposed that a representative 'National Bibliographical Advisory Council' shall be responsible for determining priorities and promoting and extending such services, as well as for stimulating research and for co-ordinating library and information

service activity. It would also be responsible for improving the co-ordination of bibliographical services, including abstracting and indexing services, for encouraging better provision of reference and bibliographical facilities in libraries, and for acting as a link with international bodies concerned with planning bibliographical and information services. The executive functions would be entrusted to a national bibliographical centre with an adequate professionally qualified staff and charged with establishing a clearing house for information on resources (including compiling and publishing detailed guides to sources of information and bibliographical guides of all kinds as well as sponsoring and organizing regional centres of information); establishing and controlling a full national bibliography, present and retrospective; establishing full union catalogues; carrying out research and serving as a clearing-house of information on research; and acting as the secretariat to the advisory council.

Mr. Corbett discusses the wider background of these proposals in the article already mentioned and in doing so indicates the limitations of the Government's own action in establishing the Office for Scientific and Technical Information. The planning for a National Reference Library gives Britain a unique opportunity to develop this to include first an information division and secondly a research division to stimulate and co-ordinate existing experiments and studies in scientific communication, classification, abstracting, indexing and the use of literature as well as to promote new studies which might arouse fresh interest in these professions and raise their status—a matter with which the present Minister for Education and Science has already indicated his concern. Mr. Corbett dismisses as entirely inadequate the Advisory Council for Scientific Policy's mild reference to the need for the closest liaison between the new organization and the National Reference and Lending Libraries, both of which he would place under the new Office and in close liaison with any branches of the Ministry of Technology serving this field. He does not refer, however, to the probability that there might be some overlap or confusion with the work of the national bibliographical centre proposed by the Library Association: that position could well be clarified by another Scientific Information Conference such as the Royal Society announced in 1948 or by a special investigation by a high level committee. Such a suggestion, however, is advanced to help convince the scientific community and the Government alike of the urgent need for a sound and comprehensive policy.

Mr. Corbett, however, suggests that a reference centre is needed for science and technology such as was proposed and supported by the Advisory Council for Scientific Policy fifteen years or more ago. Although that plan was abandoned ten years ago, Mr. Corbett still sees the need and the possibility of such a centre arranged in three divisions, of which the National Reference Library (to be built on the south bank) would be the basic unit, but dynamically extended to include an information division and a research division. This would be developed from the extensive Patent Office Library and would be the heart of the national centre and energetically administered. Complemented by the other two divisions, its resources would go far to satisfy the needs of British science, technology and industry. If the Library remains under the British Museum Trustees, Mr. Corbett insists that it must work in close harmony and conform in policy with the scientific and technical requirements of the two other divisions and their Council.

Whether such a course is practicable or even advisable seems doubtful. So little progress has been made and the record of frustrations and disappointments is such that there would appear to be sound reasons for separating the reference library entirely from the British Museum and relating it much more closely with the National Lending Library for Science and Technology in the Office for Scientific and Technical Information. We do not hesitate in war to change commanders who fail to win victories, and we should not be more reluctant in peace, in such vital matters as this, to replace those who fail to produce the energy and vision needed for results. The time is long overdue for a full enquiry into the reasons for such prolonged delay: the Estimates Committee has often enquired into matters far less prejudicial to the public interest.

Mr. Corbett makes no such comments himself, but there is a pointed reference to the possible effect of one or two driving personalities on the establishment of a new organization and on attracting to it imaginative staff. He also notes the need for a comprehensive register of scientists and their work—here again the division of responsibility between the Ministry of Technology and the Department of Education and Science does not seem likely to conduce to efficiency. It would probably be far more effective if one Ministry or the other were made responsible for establishing registers of scientists and of scientific research in progress and also studies of scientific and technical manpower.

Organization apart, there can be no question as to the opportunities which confront the new Office for Scientific and Technical Information. Mr. Mallaber's paper displays some of these in the field of research and indicates how random has hitherto been the nature of the subjects investigated. Much of it has been the experimental investigation of theories to establish hypotheses. Librarians have not been particularly enamoured of what might be called pure research—the free collection and association of data from which new and perhaps unexpected information may emerge—but Mr. Mallaber believes that such work needs encouraging, though it is less likely than the former to produce immediately useful results. The third type—development work—has been little pursued in Britain largely on grounds of cost. While he suggests that in the next few years the Library Association should concentrate on securing a full and balanced statement of what research is needed and in creating within the profession an appreciation of the importance and value of research, he looks to the Government as the main source of funds.

Here again there is a question of the relations between the Library Association and the new Office which brings out the vital importance of the professional contribution. That appears also in the compilation by the Colleges of Technology and Further Education Sub-Section of the Association of a revised edition of recommended standards of library provision in such institutions, recently issued under the title *College Libraries*†. These new standards attempt to take into account such developments as the growth of liberal studies and the widening of curricula, and are designed to assist the provision of sound and comprehensive library services in colleges of art, commerce, technology, and further education, etc. They cover resources required for efficiency such as books and

other material, staff, buildings and finance, and in issuing this revised edition the Library Association has rendered a real service to further education. First things come first and while nothing can replace the need for energy and vision and sound judgment at the centre the effectiveness of any national policy depends largely on its continuous support by professional action at all levels.

Still more recently, an article in *The Times* of August 10 stated that temporary accommodation has been found for the National Reference Library for Science and Invention in Central London and that an announcement from the Ministry of Public Building and Works might be expected within the next few weeks. At the same time the article, recapitulating briefly the history of the whole project over at least fifteen years, severely indicted successive Governments for procrastination over a vital matter, and quoted Sir Frank Francis as saying that the whole scheme was in the melting pot at the moment. The article drew a letter on the following day from Sir Frank himself, agreeing as to the vital importance of this Library in connexion with the need for an increased effort in science and technology and maintaining that the plans submitted to the Royal Fine Arts Commission in 1963, worked out in the expectation that the Library would form part of a new Patent Office building, would provide a scientific library service second to none. Nevertheless, quite apart from the uncertainty arising from the Government's severe curb on spending announced in July, Sir Frank admits that uncertainty over the future of the Patent Office has brought matters to an abrupt halt.

Sir Frank gave some facts as to the progress which had been made before this situation arose. A staff of 93 out of the 97 so far sanctioned by the Treasury had been recruited—with the present staff in the Patent Office Library the total is expected to be about 200—and in collaboration with that Library they are already surveying and co-ordinating the collection in the Patent Office Library and the British Museum Library, filling gaps and purchasing up-to-date serials and monographs. The trustees of the British Museum have given strong support to all that has been done and are gravely disturbed at the obstacles to their plans. Sir Frank added that the advisory committee under Prof. H. J. Emeléus, set up by the Trustees to advise on the services of the new library, had not met simply and solely because the delays and uncertainties made nonsense of any such meeting—as they do in fact of any thought of a national policy until the Government wakes up to the vital importance of the matter and realizes the mischief that it and its predecessors have done.

This, as Prof. R. S. Hulton rightly observes in a subsequent letter of August 16, is the real problem. From what E. M. Nicholson is reported to have said, a major culprit at the moment is the Department of Education and Science, but the Ministry of Technology is equally to blame. Certainly it is to be hoped that neither scientists nor industrialists will be deluded by the establishment of a new Office for Scientific and Technological Information while the first essentials for promoting Britain's industrial as well as her scientific and technological effort are neglected and disregarded. It is idle for the present Government to shrug the responsibility off on to their immediate predecessors: if the first post-war Labour Governments had shown sufficient insight and energy the project would have been completed long since; if the present Government had acted on the plans available to it last autumn, to which Sir Frank Francis referred, the project would have been well started.

† *College Libraries: Recommended Standards of Library Provision in Colleges of Technology and Further Education and other Establishments of Further Education*. Pp. 24. Compiled by the Colleges of Technology and Further Education Sub-section of the Library Association (London: The Library Association, 1965.) 6s 8d. (L.A. members 5s.)

What has to be realized, and realized at the top, is that the needs of science and of technology are not to be met on the cheap or by party trickery. They require far-sighted constructive planning, free from party prejudice and dogma, and sustenance by adequate resources which, once committed, are immune from pressure. Only so can serious waste be avoided. There are members enough in the present House of Commons, quite apart from the House of Lords, judging by some recent speeches, who have some understanding of the implications both of a National Reference Library for Science and Invention and of a genuine national library policy. So, is it too much to expect that they, firmly supported by professional associations of scientists and technologists, including the learned societies, should induce the Parliamentary and Scientific Committee to raise the issue and make matters really uncomfortable for any Government to continue to procrastinate? The Government must make the decisions and allocate the resources required to establish the National Reference Library for Science and Invention at the earliest possible moment and make a national policy not only possible but also a reality.

## ADRENAL STEROIDS AND THERAPY— A CRITICAL ASSESSMENT

### Adrenal Steroids and Disease

By Cuthbert L. Cope. Pp. xi+827. (London: Pitman Medical Publishing Co., Ltd., 1965.) 126s. net.

THIS book bears the imprint of the dual qualification of its author as a physician and a biochemist; it is written with an expert knowledge of steroid biochemistry while all the time having the clinician's needs in mind. It has the attraction, nowadays so rare, of a book written by a single author, and yet covers a wide field of medicine and therapeutics, since corticosteroid therapy had, and still has, application far outside the range of diseases of the adrenal gland.

The introductory chapters deal briefly with the chemical structure, the biosynthesis and the occurrence of the natural adrenal steroids. Their concentrations in blood and other body fluids, their metabolic transformation and the estimation of their metabolites in urine are discussed in the next chapters. There is a particularly useful analysis of the origin of the different urinary metabolites. This enables the reader to assess the very variable value of the many biochemical methods employed to test adrenal, pituitary or testicular function by steroid analysis in body fluids. Interesting examples of results of steroid estimations made in blood apparently contradicting findings in urine, or of different methods used in the same body fluid giving divergent answers, will serve as a useful guide through clinical biochemical literature. Tests of adrenal function occupy one chapter; this is followed by a discussion of more general questions, such as the role of the adrenal in stress, the evidence for or against the existence of 'diseases of adaptation', the relation between adrenal steroids and inflammation or immunity. Much space is devoted to the response of the body to prolonged treatment with steroids or with ACTH, to the question whether the response to stress of either the adrenal gland or the pituitary may be permanently inhibited by such treatment, and to the demonstration of the extreme scarcity of reliable data on these problems.

After several chapters dealing with specific adrenal diseases of the type which has been known for many decades, there is a discussion of the discovery of aldosterone, its physiology and pathology, and its synthetic antagonists. The evidence for and against the existence of a steroid which causes loss of sodium occupies one chapter,

and the changing views on the relation between hypertension and the adrenal cortex another. A chapter on the synthetic analogues of cortisol serves as an introduction to the discussion of indications and complications of steroid therapy. It is here that careful consideration has to be given to the multiple actions possessed by adrenal steroids, some of which are desirable in certain conditions and dangerous in others, and to the dangers of long-term effects which may lead to a kind of addiction, to withdrawal symptoms, and to rebound phenomena of the underlying disease. No other medicinal substances are apt, as the steroids are, to obscure the complications of their own administration and to lead to disaster when their administration is stopped. The book concludes with chapters on special problems. One deals with the use of steroids in collagen diseases, in disorders of the blood and in ophthalmology. The fact that the eye can be treated with steroids by local application carries the great advantage of avoidance of systemic signs of overdosage, but this does not mean that treatment need not be cautious and circumspect. One chapter discusses the discovery of substances which inhibit adrenal synthesis by interfering with  $\beta$ -hydroxylation, and another the clinical implications of the observation that certain steroids cause fever. Adrenal function in pregnancy, in the foetus and in the new-born, occupy special chapters. Another is devoted to the recently discovered masculinizing effect on the foetus of treatment of the mother with progestins, and a further chapter to the occurrence of signs of hyperadrenalism in malignant disease not located in the adrenal gland. Each section has its own detailed bibliography.

The author's views are balanced and cautious, and are expressed in a clear, readable style. Diagrams and short summaries help to clarify and recapitulate conclusions drawn from an often bewildering mass of contradictory claims. Fallacies of arguments based on inconclusive evidence are pointed out, and the reader is shown how to distinguish incontrovertible biochemical evidence from data which can be interpreted in more than one way. The clinician interested in the rationale of steroid therapy and in diseases of the adrenal gland will be the first to profit from this book, but the laboratory worker interested in the practical consequences of endocrinological research will find it just as fascinating.

MARTIN VOOGT

## RABBIT THROUGH THE LOOKING-GLASS

### The Rabbit In Eye Research

Compiled and edited by Prof. Jack H. Prince. Pp. xvi+652. (Springfield, Ill.: Charles C. Thomas, 1964.) 87 dollars.

THE publisher's claim that this compendium represents a complete study of the eye of the rabbit is very nearly true. It covers the anatomy of the bony orbit and of the ocular adnexa. There is a detailed account of the morphology and physiology of the globe wherein the chapters on the chemistry and aqueodynamics of the ocular fluids and on the retina and optic nerve are outstanding—the former by its excellence, the latter by its lack of critical appraisal of the material with which it deals. The chapter on the electron microscope is beautifully illustrated and lucid in the extreme. The book concludes with a description of the vascular and neurological systems, and a chapter on the effects of sundry electro-magnetic and ultrasonic radiations.

Why was this well-organized book written at all? Prof. Prince assures us that "while one must always remind oneself of . . . differences during experimental work on the rabbit, the similarities between this animal and man are numerous enough to justify its continued use in the ophthalmic laboratory, with due caution". The extent of

these similarities is a matter of opinion, and the cynic may be forgiven the thought that if cats had been cheap in pre-myomatosis days, a case might now be made for writing a practical book on cats—in spite of their tapeta. Monkeys would be even better. Some examples serve to illustrate this point: the solidity of the walls of the eye-ball of man more nearly compares with that of these tissues in cat than in rabbit. This is a matter one recalls whenever tonometric data are compared for different species, and here we learn (p. 236) that aqueous flow rates in rabbit eyes have to be derived from calibration tables constructed for human eyes. Anyone conversant with the trabecular meshworks in the two species will be pardoned for raising his eyebrows over this extrapolation. Secondly, the function of the rabbit retina differs from that of man more than does the feline. As this difference extends to visual behaviour, and there is no evidence of any typically human photopic apparatus in the rabbit, any hope for a search for cone pigments in the rabbit retina would not appear to be prompted by a marked sense of priority. Again, a considerable part of the section on the electron microscopy of the retina contains examples culled from work on guinea-pigs. Even though there are many similarities between the two species in this respect, this is supposed to be a book on the rabbit eye, not on comparative anatomy.

The price of the book is more than £13. For all the troubles now befalling sterling this is a fearful amount of money. At that price one could expect a more uniformly high quality in graphs, especially when they are "after". But the fact remains that the book is a classic of its kind: those who can afford it will find reimbursement in the time saved in looking for references by using the extensive lists after each chapter and also the excellent index.

R. A. WEALE

## ANTIBIOTICS RESEARCH

Recent Advances in Chemistry and Biochemistry of Antibiotics

By Prof. Hamao Umezawa. Pp. iv+264. (Tokyo: Microbial Chemistry Research Foundation, 1964.) 1800 yen; 5 U.S. dollars.

**R**ECENT *Advances in Chemistry and Biochemistry of Antibiotics*, the first book to be published by the Microbial Research Foundation of Japan, sets out to present a readable account of the more important discoveries in the chemistry, biochemistry and mode of action of antibiotics from 1958 to about mid-1964. So far as possible, a chemical classification has been adopted.

The first chapter deals with sarkomycin, griseofulvin, puberulic and stipitatic acids and a host of other non-nitrogenous antibiotics, many of which, like helvolic acid, cephalosporin *P* and fusidic acid, have structures suggesting biogenesis by way of mevalonate. A brief chapter on the glutarimides precedes polyene antifungal agents and macrolides. The important group of antibiotics derived from amino sugars, including streptomycin, blumycin, neomycin, paromomycin and kanamycin, follows and concludes with a brief account of the mode of action of streptomycin and kanamycin. Brief reference to *N*-glycoside antibiotics is followed by the penicillins and cephalosporin *C* and a lengthy chapter on antibiotics derived from amino-acids and polypeptides. The remaining chapters are devoted to the tetracyclines, aromatic nitrogen-containing and heterocyclic antibiotics, and conclude with a section on miscellaneous substances such as the antibacterial streptolydigin and the antiprotozoal agents teleocidin *A* and *B*. Structural investigation among many of the substances in the final chapter continues, hence classification is biological rather than chemical.

The style of the book is reminiscent of *Annual Review of Biochemistry*, for which much of the material was originally

written before it was decided to publish it in its present form. In one or two places the text tends to be a catalogue of physical and chemical data and, while this is invaluable for reference, it tends to make those sections less readable. Prof. Umezawa has, however, succeeded in producing a text which is brief and comprehensive but not incomprehensible. It is perhaps surprising that there is no mention of cephaloridine, although the closely related 7-(2-thienyl-acetamido)desacetoxycephalosporanic acid and cephalosporin *O*<sub>4</sub> are both included.

A few typographical errors were found; for example, "bond" (line 7, p. 107), "streptomycos" (line 16, p. 179) and "guanidino" (line 23, p. 67) are mis-spelt, and the numeral under the structure for rhodosamine (p. 158) should be *T*-XXIV. According to references 137 and 139, the acetoxy group in formula *I*-LVI (p. 27) is misplaced and it is not made clear if this is a revised structure communicated to the author. The page numbers to references 137, 144 and 145 are incorrect and the symbol for tautomerism and not mesomerism should be used at *HT*-XVIII (p. 183), while acetylenedicarboxamide is described on p. 101 and not 102 as indexed. These very minor criticisms are, however, more than abundantly offset by Prof. Umezawa's masterful handling of this subject. In particular, those chapters dealing with amino sugar, amino-acid, peptide, heterocyclic, glutarimide and nitrogen-free antibiotics reflect his expertise, and the penicillins and tetracyclines are excellently presented.

This book provides a wealth of up-to-date information, which, together with almost fifteen hundred references to reviews and original sources, makes it a valuable addition to the bookshelf of all organic chemists, biochemists, and microbiologists interested in current progress in this field of natural products. Prof. Umezawa has set a high standard for future companion volumes.

A. M. COMBIE

## UNIFORMITARIANISM VERSUS NEO-CATASTROPHISM

Bombarded Earth

An Essay on the Geological and Biological Effects of Huge Meteorite Impacts. By René Gallant. Pp. 256+27 photographs. (London: John Baker Publishers, Ltd., 1964.) 36s. net.

**T**HE great triumph of the British school of geologists represented by Hutton, Playfair and Lyell was to bring order out of chaos simply by postulating the doctrine of uniformitarianism. This assumption removed the need for the continual invocation of catastrophes required by Cuvier's school of thought, with its demand for the 'fixity' of species. The death knell to such ideas was given by Darwin's theory of gradual evolution.

In the past few decades, however, it has become clear that meteoritic impact must have played some part in the shaping of the Earth's features. The basic question at issue is whether the overall effect of meteoritic impact is small or significant. In *Bombarded Earth*, Gallant introduces a hypothesis of neo-catastrophism, the mechanism of which is meteoritic impact, not supplanting uniformitarianism but complementing it.

The first quarter of the book is devoted to a treatment of meteoritic impact, which, by and large, but with certain reservations, represents the consensus among most astronomers and many geologists to-day. From this point of departure, Gallant devotes a chapter to the possibility of shifts of the polar axis and changes in the length of the day by virtue of meteoritic impact on the Earth. Apart from the effect of meteorites in this connexion, such changes of small magnitude are known to occur at present and the causes of some of them are known (Gold, *T. Nature*, 175, 526; 1955). Gallant finds that significantly large shifts can be brought about without fragmentation of the Earth itself only by a relatively long sequence of

impacts by asteroids of reasonable size. He makes his calculations on the basis of conservation of energy in the impact whereas the correct balance to use is conservation of momentum (see the discussion of impulsive forces and Carnot's theorem in J. S. Ames and F. D. Murnaghan, *Theoretical Mechanics*, Dover Publications, New York, 201 and 278, 1958). The former method is not valid but probably gives answers approximately correct.

Gallant discusses next the possibility of slip of the Earth's crust over the underlying mantle by virtue of meteoritic impact, producing continental drift. Since most suggested mechanisms of creating the drift are inadequate (except possibly thermal convection), he postulates sliding of major land masses over the asthenosphere (interpreted as plastic) consequent to meteoritic impact. In later chapters, he invokes this process to interpret the data on palaeontology, palaeoclimatology, and palaeomagnetism that Wegener's hypothesis is frequently called on to explain. In this connexion, he stresses the apparently sudden extinction of various species (such as the dinosaurs at the end of the Cretaceous) as evidence of catastrophism.

However, a rule of thumb exists in the field of the weapon effects of craters from nuclear explosions on the ground, implying that a heavily reinforced concrete structure underground and only narrowly outside the crater formed by the explosion will survive, at least in large part. The important point is the very high rate of attenuation of a shock wave to seismic amplitude in the ground outside of the crater. Thus, it is extremely doubtful that Gallant's mechanism to produce slip of the Earth's crust can be operative.

Gallant refers with examples to the frequently suggested possibility that many of the large and roughly circular features on the Earth are meteoritic in origin. In this connexion, he mentions the theory which I have put forward (*Nature*, 190, 1048; 1961) that the terrestrial ocean basins were formed in this manner, far back in the Pre-Cambrian. However, he does not fall into the absurdity of claiming that all such roughly circular features are meteoritic in origin.

Some errors of fact were noted. On p. 79, meteor velocities for hyperbolic orbits are quoted—now known to be rare or non-existent. The temperature  $10^4$  °C given on p. 180 for impact of a large meteorite is far higher than the actual figure of approximately  $10^3$  °C. The latter value is large enough to produce thermal ionization and thus an intense flash of light in the impact, but not enough to excite nuclear reactions, as stated on p. 181.

An unfortunate aspect of the argument of *Bombarded Earth* is the suggested correlation of impacts of large meteorites with events in the historical records of ancient peoples. Moreover, the discussion in many cases contains a rather larger measure of unverifiable speculation than most specialists would be willing to accept.

J. J. GILVARRY

## INDEX OF CRYSTALS

### The Barker Index of Crystals

Vol. 3. Crystals of the Anorthic System, Part 1: Introduction and Tables. Pp. vi+94. Part 2: Crystal Descriptions A.1 to A.831; Atlas of Configurations. Pp. vii+text. Edited by M. W. Porter and L. W. Codd. (Cambridge: W. Heffer and Sons, Ltd., 1964.) 240s. per two parts.

THE *Barker Index* facilitates the speedy non-destructive identification of crystalline materials. Volumes 1 (*Nature*, 169, 851 (1952)) and 2 (*Nature*, 180, 821 (1957)) covered some 6,500 substances, and this final volume, listing some 800 triclinic (anorthic) crystals, brings a monumental undertaking to a praiseworthy conclusion.

Given any crystal in a standard setting and orientation, a systematic description becomes possible in terms of particular interfacial angles. This principle, conceived by

Federov and rendered workable by Barker (whose *Systematic Crystallography* was published in 1930), faces its most searching test when applied to crystals of the triclinic system. Here, Barker's rule of simplest indices sometimes fails to resolve ambiguities of setting, and much of the credit for overcoming this difficulty, mainly by means of topological and projective relationships, must go to Prof. Terpstra and his colleagues in Groningen. Because of this unavoidable complexity, Volume 3 has nearly double the average number of pages per crystal compared with the previous volumes, while matrix methods of checking angles have involved the use of a computer. Is it, perhaps, a little optimistic of Dr. Perdok to suggest that "the chemist with merely a basic crystallographic knowledge" would be able to use this volume of the Index?

The basic pattern remains similar to that of Volumes 1 and 2. In Part 1, after an explanatory introduction (including worked examples) by Dr. Hey, Mr. Codd gives an account of the use of the bond matrix for calculating crystal angles, and Dr. Perdok surveys the work done in Groningen. Then follows a table of multiple tangents (for the third time!), the main determinative table of classification angles, and more limited auxiliary tables of refractive indices, densities and melting points for confirmatory purposes. Two new features now appear: first a 48-page table, constructed from the output of the Oxford University computer, lists the bond matrix and its inverse for nearly all the crystals; then a 94-page table of configurations is given to facilitate selection of correct crystal setting and orientation. Part 1 concludes with the customary threefold list of substances, although it is to be regretted that some names, for example, A.760, are less informative than they would be had they followed the nomenclature recommendations of the International Union of Pure and Applied Chemistry.

The crystal descriptions, which make up the greater part of Part 2, are not only valuable in their own right, they are a useful supplement to the American Society for Testing Materials (A.S.T.M.) powder index, for there are only 13 substances in common. Part 2 concludes with a colourful 30-page atlas of configurations, provided as an alternative means of crystal setting by reference to standard zonograms.

It is a credit to both editors and printers that accuracy continues high and errors are few—a power missing on p. 42, and a mis-spelt word on p. 49; a formula error in A.269, while A.88 is assigned six A.S.T.M. index lines instead of three. Economy in cross-reference and space might have been achieved by listing the bond matrix immediately after the crystal description, and clarity in the introductory chapter might have been better served by distinguishing figures occurring in the text from those so usefully collected at the end of this section. But the omission of anorthic minerals from the present volume is deliberate. While we applaud the vision of the Barker committee, the workmanship of an international team and the devotion of the joint editors, they promise us a mineral supplement for good measure.

R. HULME

## A SYSTEMATIC REFERENCE TO PALEARCTIC BIRDS

### The Birds of the Palearctic Fauna

A Systematic Reference. Non-passeriformes. Vol. 2. By C. Vaurie. Pp. xx+763. (London: H. F. and G. Witherby, Ltd., 1965.) 147s.

DR. VAURIE'S first volume, covering the Passeriformes, was published in 1959 (*Nature*, 184, 666; 1959); this second volume deals with all the non-passerine species, 559 in number. The complete work provides a new base-line for the taxonomic and geographic study of the species and sub-species of birds native to Greenland, Europe, North Africa, and the northern part of Asia,

It will certainly be a standard work of reference for many years to come.

The work has this clearly defined purpose; and it is not within its scope to give descriptions or illustrations of species, and still less their life-histories. It does, however, mention the distinctive characters of sub-species, in order to indicate the trends of variation. Some information is also given about habitat, which is relevant to distribution, although, as the author points out, its nature varies geographically and seasonally, and can in the longer term be influenced by changing environmental factors.

Thus, Dr. Vaurie has kept to his particular and surely sufficient task of systematic presentation, based on many years of work in the principal museums of Europe and North America; the institution which he serves, the American Museum of Natural History in New York, nowadays has the Rothschild Collection earlier used by Hartert at Tring. The author has worked in close touch with Soviet ornithologists, and this has been of great help in enabling him to deal effectively with the forms found in northern Asia. In the course of his investigations he has published many notes on particular groups, allowing him now to give the end-results without detailed discussion except where it is desired to direct attention to some outstanding problem. All references to other sources have been checked by him with the original publications. The whole massive undertaking bears the stamp of expert authority.

In his taxonomic presentation, Dr. Vaurie directs particular attention to the trends of intraspecific geographical variation. There is a welcome flexibility in dealing with sub-species, which he places in three grades of validity—well differentiated, not well differentiated but acceptable, and unaccepted but worthy of mention (mostly points on a cline).

The other facet of the presentation gives the distribution of each species and sub-species within the region. The information is given in some detail and is a most valuable feature of the book. Extra-limital distribution and the existence of extra-limital sub-species are more briefly indicated.

Although other taxonomists may not accept the author's judgment on every point, the existence of this work will constitute a challenge to state reasons for any different practice. Ornithologists in general may be less willing to follow Dr. Vaurie in certain unexplained departures from the traditional order of species within a genus, or of genera within a family; these sequences have long since ceased to be regarded as more than convenient, and it is not clear that new arrangements have any special merit.

LANDSBOROUGH THOMSON

## TOWARDS A STRATEGY OF MATURITY

### The Scientific Age

*The Impact of Science on Society.* By L. V. Berkner. Pp. xvi + 137. (New Haven and London: Yale University Press, 1964.) 30s.

IN these Turnbull Lectures, delivered at the University of Yale, Mr. L. V. Berkner discusses in succession the economy of plenty, advanced education for a new age, the relations between science and government, science and philosophy, and what he terms "a strategy of maturity". In the first he explains the significance of science and technology for the economy of the United States as a whole. However, while he emphasizes the way in which science and technology contribute to the stability of the economy, his attitude is startlingly different from that of Prof. J. K. Galbraith. He seems inclined to advocate production and change for their own sake: he never challenges the tendency for the process of production to create 'needs'. His more constructive and fundamental thinking is found in later chapters, for

example, when he considers the place of the universities in the changing society of the United States. Despite the close relations to conditions prevailing in the United States, of which he is somewhat critical, his comments on high-school education and university education should be pondered in considering the expansion of higher education in Britain, particularly in relation to the proportion of technicians to postgraduates who are being trained.

In his chapter on the role of the universities he comments freely on Clark Kerr's *The Uses of the University*, and again refers to this in his brief outline of the problems of Government finance for research and the selection of research projects. Here also he is critical of present-day policies and urges that up to 35 per cent of overhead expenses should be allowed against direct costs under research grants as encouraging institutional support for younger and unknown scientists, and the initiation of new, but soundly conceived, projects as well as encouraging better internal administration of public funds and greater freedom for the scientist while reducing Federal control of the institution. Much of his discussion of science and philosophy stems from Lord Snow's *The Two Cultures*, the broad thesis of which he accepts. This he regards as fundamentally a problem of communication. He is concerned that failure to comprehend the character and power of the means available for improving the condition of the bulk of mankind may lead to the degeneration of our civilization. This is a task which calls for the contribution of the humanist as well as of the scientist if we are to achieve the discipline of mind and body that will master the machine.

When he outlines his "strategy of maturity", Mr. Berkner comes nearer to the point of view of Prof. Galbraith. He considers that at present the educational capacity of the United States, particularly with regard to the proportions of learning and skill required, the policies governing the encouragement of science and the attitudes of society generally, are potential sources of instability. Causing instability also in a similar fashion are: the potential elimination of poverty by extending to every level of society the opportunity for higher education; the increasing lack of balance in social opportunity in a world divided between the highly industrialized nations and the underdeveloped areas; and the radical change in the character of war and of justice among nations.

On the educational side, he looks for a solution to the improvements in curricula and in teaching at the elementary and secondary school level which are already leading to progress in individual capacity, as well as to improved articulation between school and university. Improvements which could also help include increasing the opportunities for students to participate in research at an early age with more effective presentation of the idea content in university courses, and the shift of professional emphasis and specialization to the graduate school. However, he suggests that in the next decade in the United States the emergence of the junior college may be the most far-reaching development, and this suggestion also has its implications for Britain. He has some cogent observations on the character of business management and on training for management and more especially on relations between business and industry. He writes with brevity and realism on social change, the problem of poverty and population and the challenge of the underdeveloped peoples. Implicit in it all is the insistence on honest and clear thinking regardless of political prejudice. We must face frankly the real issues of the time, and a strategy of maturity would arise from any rational attitude of mind that evaluates alternatives objectively and tests each step analytically, seeking to utilize the optimum advantages that our scientific culture affords. Outside the American context, Mr. Berkner offers little in the way of constructive proposals, but nevertheless he is as challenging and stimulating for the British readers as for the American audience he originally addressed.

R. BRIGHTMAN

### Measurements for Stresses in Machine Components

By V. F. Yakovlev and I. S. Inyutin; translated from the Russian by J. J. Cornish. Pp. xv+135. (Oxford, London and New York: Pergamon Press, 1964.) 50s.

WHILE this text has all the signs of careful and reliable translation, it remains a somewhat slender and in some respects ill-balanced treatment of experimental stress analysis. The authors support their discussion by 69 reasonably well-chosen illustrations (mainly line diagrams) and 43 bibliographic references—almost entirely selected from Soviet publications. Though a useful book for engineers and research workers deeply concerned with the strength of structures and machine components, it has little general appeal as a teaching text, and the publishers rightly claim no more than that it "... will be of interest in graduate departments of engineering ...".

It is not unduly purist to point out that, despite the title, the book is concerned with the more familiar situation, namely, measurement of strain and subsequent inference of stress. The central theme is devoted to techniques, based predominantly on the electric resistance strain gauge, for assessing the distribution of stress inside solid bodies: the greater part of the text deals essentially with static loading, but the final chapter touches briefly on dynamic and impact conditions. The technique requires that unbonded strain gauges—sufficiently small and close together to justify the assumption of measurement at a point—should be embedded in models (not necessarily full-scale) cast in epoxy resin. Practical aspects are discussed in considerable detail, covering manufacture and positioning of the gauges themselves, appropriate electrical measuring circuits, correct treatment and curing of the resin, together with advice on materials suitable for the moulds. Illustrations of how the procedure may be applied are then given in terms of simple bending of beams, stress concentration at a circular hole in a flat-plate, two mutually perpendicular cylinders which are pressed against each other, and the pressure of variously shaped discs on an elastic half-space. Mathematical analysis is used somewhat sketchily and it is probably at this point that workers having only a limited background in stress analysis will find the book unsatisfactory.

Although the opening chapter ranges over most basic methods of experimental stress analysis, much discussion is superficial. In particular, scant attention is paid to the process of inferring the magnitude and axes of principal stresses from surface strain gauge observations. This particular inadequacy runs through to the main theme of the book; and the inexperienced reader is left much in the dark on how exactly to infer principal stresses at a point where he has no prior knowledge whatever of the axes of the principal strains.

However, despite its weak points, this book will be of interest and practical value to the experienced workers; and this, in fairness, seems to have been the primary aim of the authors.

### Theories of Nuclear Fission

By L. Wilts. (Oxford Library of the Physical Sciences.) Pp. x+132. (Oxford: Clarendon Press; London: Oxford University Press, 1964.) 18s.

THE study of nuclear fission processes has been an active field for more than twenty-five years, but many features still remain to be explored experimentally and discussed theoretically. However, it is a good moment to review the progress made over the past decade.

In his small monograph Dr. Wilts discusses present-day models of fission, including the liquid drop, adiabatic and statistical models. He starts with a clear and concise description of the historically important liquid drop model.

The elegance and precision of this model, which has always appealed to physicists, are exemplified by this treatment. Its limitations are explained and then the discussion moves to more recent models. Rather than discuss them in detail the main features are listed, their importance considered, and the region of validity examined. Probably this style of treatment is essential in a monograph. For the same reason only a limited range of the experimental material is covered, but the most pertinent is used in order to test the models. The mathematical presentation is fairly elementary, making *Theories of Nuclear Fission* quite easy to read. The pragmatist may feel that this prevents an exact understanding of some parts of the subject. However, to those unfamiliar with the modern developments in the theory of fission, this monograph will be a useful guide, while to those engaged in the field it is a stimulating review. Altogether it is a well-written and well-presented monograph.

P. A. EGHLESTAFF

**Theory and Methods of Nuclear Reactor Calculations**  
Edited by G. I. Marchuk. Authorized translation from the Russian. Pp. viii+199. (New York: Consultants Bureau, Inc., 1964.) 40 dollars.

*THEORY and Methods of Nuclear Reactor Calculations* is a collection of fifteen papers dealing with neutron transport theory, and in particular methods used in the design of reactors, with a group of three papers dealing with topics such as optical model calculations and inelastic scattering of neutrons by iron. It is a translation by the Consultants Bureau, New York, of the original Russian text published in 1962, and edited by Prof. G. I. Marchuk. The translation has been carried out efficiently.

The papers dealing with reactor theory discuss methods which are useful in practical work—they are mainly numerical in character. The first two papers deal with the application of the spherical harmonics method—a method which has been superseded in many cases by the direct numerical integration *S<sub>N</sub>* methods of Carlson, which are also discussed. Other subjects of technical interest which are mentioned include: the calculation of the burn-up of poisons in reactors, the thermal neutron spectrum in a homogeneous mixture of moderators at different temperatures and neutron resonance absorption. The paper which deals with the optical model of the nucleus is concerned with the calculation of the transport cross-section—in this paper the choice of various parameters in the model does not seem to be always justifiable. However, it is a useful compilation of papers of interest to reactor physicists.

J. H. TAIT

### A Petrography of Australian Igneous Rocks

By Dr. Germaine A. Joplin. Pp. xiii+210. (Sydney and London: Angus and Robertson, Ltd., 1964.) 63s.

THIS short text-book of petrography, presented along genetic lines, is illustrated entirely by descriptions of rock-types occurring in Australia and it has doubtless been written to provide advanced students in Australia with a course of instruction based on local material. The work, however, is well documented and it will be useful elsewhere both as a précis of Australian literature and as a ready source of references to it. The book is in three parts, of which the first is concerned with classification, nomenclature, and textural terms (including brief glossaries of rock names and of textures), the second with the rocks of non-orogenic regions (tholeiites and alkali basalts), and the third with rocks of the orogenic belts (alpine ultramafics, spilites, andesites, granites). Shoehornites and their differentiates occur in both environments. Dr. Joplin has given a lucid exposition of the relationship between magma-type and tectonic environment, and in this connexion her work deserves to be widely read. It contains 39 tables of chemical analyses and is illustrated by about 150 microdrawings.

C. F. DAVIDSON

## INTERACTION OF TECHNOLOGIES\*

By DR. J. W. S. HEARLE

Department of Textile Technology, University of Manchester  
(Manchester College of Science and Technology)

**THE importance of materials.** The use of materials is central to all technology. The rocket technologist may calculate the thrust needed or define the controls which must be used; the computer technologist may specify the functional operations; the electronic circuit designer may think of the current and voltage relations; the architect may design a building; even the artist or musician may conceive their creations: all these things can be done in the abstract; but for execution of any of the plans real materials must be used. With other technologies, such as chemical engineering, metallurgy, textile technology, and much of mechanical and civil engineering, it is virtually impossible to isolate any aspect of the subject which is not a direct materials problem. Ultimately the solution of any technological endeavour can be reduced to putting the right material in the right place.

Materials science is thus a meeting-ground for many technologies. There are others, such as the provision of power, instrumentation and control, probability and statistics, the similarity of mathematical forms, and the application of the laws of mechanics. These are all areas where the practitioners of different technologies can profit by common discussion. None is more important than the provision of materials with the properties needed to do the job.

**New materials and advancing technology.** We can see in materials science an immediate interaction in technological advance. New materials generate new technical possibilities, and so new industries arise; while, contrariwise, the demands of advancing technologies force the materials technologist to develop new materials. Sometimes the new material triggers the creation of a new utilisation technology, and sometimes the demands of an advancing technology trigger the production of a new material.

This sort of interaction is seen in the relation between electronic engineering and semi-conductors, between fuel technology and rockets, or between aircraft design and advances in metallurgy. It is seen in the development of polymer technology in the past forty years which has led to the vast new industries of plastics, man-made fibres and synthetic rubbers: these in turn have influenced many other technologies—building, adhesives, textiles, tyres, engineering, appliances, furniture, packaging, to name but a few—while, on the other hand, the demands of space technology have recently led to important advances in high-temperature polymer technology. At the frontiers of advancing technology, there is a ferment of ideas associated with advances in materials science.

**Older technologies: the creation of new demand.** In well-established industries using readily available and well-known materials, the problems of materials technology may not be so acute. The materials available may seem to meet all the technical requirements; and the designer can get by for a time without too much thought about materials—merely selecting them as components on the basis of past experience or from a cursory check of tables of standard products. Even here, advances in materials technology must be watched, if for no other reason, in order to ensure that the material being used is the most economical. But, surprisingly, new materials often generate new and unexpected technical demands.

The advent of synthetic fibres provides a simple example. When nylon was introduced in 1938, its obvious technical advantage was toughness, and it was first used where there was an unsatisfied demand for this quality: stronger ladies' stockings, harder-wearing socks, and

better parachute fabrics were among the first uses. But then the development began to follow lines which would not have been predicted by a textile technologist in 1938. Even the requirements in ladies' stockings shifted from long life to extreme fineness—the demands of glamour outweighing the demands of efficiency. Then, with nylon and also the polyester and acrylic fibres which followed, new ease-of-care, drip-dry, wash-and-wear, crease-resistant and pleat-retaining properties were achieved in textile fabrics as a result of the heat-setting characteristics of synthetic fibres. There had been no great public demand for this: prior to 1945, the public had accepted the attributes of a cotton shirt or a wool suit as satisfactory. But once we met the advantages of the new materials, we realized how much we wanted the new properties.

As a consequence, the cotton, wool, and rayon technologists had to set to, and find ways of achieving similar properties in fabrics made from these fibres. Resin finishes which would yield drip-dry cottons, and chemical treatments which would set wool fabrics were discovered. Scientifically there is little reason why these processes could not have been discovered in the great advances in the chemical finishing of textiles in the second half of the last century, or through the work of the strong British textile research associations established around 1920. But it was not until the new material had created the new demand that the problems were tackled and solved. The whole process has been repeated following the enormously successful introduction of stretch yarns made from synthetic fibres: stretch cotton and stretch wool are following. All this is part of a revolution in textile technology, more fundamental than the industrial revolution which brought power to the machines but did not change the materials; and it has come about as a result of interaction between chemical technology, polymer technology, man-made fibre technology, and traditional textile technology—interaction, too, between mechanical and chemical aspects of fibre and fabric technology.

**Materials sciences.** The problems which arise between materials-producing, materials-processing, and materials-using technologies make one group of interactions related to different stages in the life of a particular material. But what about interactions between the technologies of different materials?

Ironically, the various materials technologies have developed with little contact between one another. Although they may have had mutual associates, the metallurgist and the glass technologist, the ceramicist and the textile technologist have not often met.

The lack of contact between materials technologists mattered little so long as each industry was run mainly on a craft basis, utilizing traditional recipes and procedures. The empirical cookery involved in the ageing and ripening of the cellulose solution used in rayon production is of little relevance to the empirical cookery of the iron smelter. It is only with the application of science that a basis for useful contact between materials technologies becomes established. The understanding of the chemistry and of the macroscopic physical behaviour of materials dates from the days of Newton, Boyle, Hooke, Lavoisier, Dalton, Kekulé, Poiseuille, Faraday, and Clerk Maxwell; but it is only in the past fifty years that we have really come to understand the fundamental nature of materials. Even to-day, although we know a lot about gases, crystalline solids, and rubbers, and have mathematical theories of their behaviour, we are still very ignorant about liquids and glasses amorphous solids.

\* See *Nature* of September 11, p. 1121 (1965).

At first, too, as scientists looked at the problems of industrial materials, there was so much to study that each materials science could develop on its own. A basic framework of knowledge had to be established. But now, as a result of the advances in pure science and in the applied sciences of various materials, contact between materials scientists is needed and is likely to yield surprising benefits. Already there are examples which can be quoted.

**Continuity and discontinuity.** In the materials of construction, strength is the most obvious technological requirement. Strength comes from continuity of structure. In metals we have a continuous band of electrons holding the atoms together, and in polymers we have a continuous network or chain of covalent chemical bonds. In strong materials, the structure of which is not so well known, this provides a clue about what we must look for. Thus in glasses there is probably a network structure though this is not so well defined as in polymers. In crystals of small molecules, the extent to which one can get strength depends on how closely the molecules can pack together in order to develop a degree of continuity in intermolecular attractions.

Conversely, discontinuity is a source of weakness. Materials fail at flaws. Here, Griffith's classical treatment of the propagation of fracture from a crack has set off a train of interactions in technology. The Griffith criterion has been applied and modified in glasses, metals, polymers and many other materials. So long as one is dealing with a pure homogeneous flawless material, one's gaze can be narrower: the properties of the particular assembly of atoms are all that matter. The modulus, that is the force needed to produce a given small strain, can be calculated from the deformation characteristics of the particular atomic bonds in the structure; and the result will usually agree well with the values for real materials. But calculations of strength will always yield too high a value, usually orders of magnitude greater than the strength of real materials. It is the unusual points of weakness that must be looked at, and not the behaviour of the bulk of the material. In studies of the rupture of real materials, we can be helped by the relevant work in the technology of all materials. The behaviour of materials at discontinuities is a general problem. A recent book on *Fracture Processes in Polymeric Solids* draws heavily on earlier work in metals and glass. On the other side, Orowan and McClintock at the Massachusetts Institute of Technology have examined the pattern of ridges produced in the fracture of gelatine and the cracks developed during the flexural fatigue of 'Plasticons', and have used the results to explain the similar effects which occur on a much smaller scale in metals.

The importance of flaws as a source of weakness has led to the recent searches for flawless materials: perfect single crystals. Diamond is the classic naturally occurring example; but now we have single crystal whiskers of metals and of materials like silicon carbide. These are fibrous in form, and in their application lessons can be learnt from the old-established fibre technologies of textiles and paper.

Curiously enough, discontinuity can also be a source of strength. It can spread out the forces on a material; it can prevent dangerous stress concentrations; it can interrupt the progress of a crack. Whereas a continuous material may be able to resist very large loads, it is liable to be brittle and to shatter under conditions where a material with the right sort of discontinuity would yield, but would not break. The crystal defects in metals, the amorphous regions in crystalline polymers, and the rubber which can be dispersed in polystyrene in order to toughen it perform this function.

In dealing with a real materials system, the technologist has to keep in mind two separate but interrelated aspects: first, the responses of each part of the system to the local stress; and secondly the influence which this has on the distribution of stress through the system. For example, the absorption of water by cellulose fibres always breaks

cross-links and makes it easier for the molecules to slide over one another: but, in rayon, with short molecules, this lowers the strength; whereas, in cotton, with longer molecules, where breakage by molecular slip is not important, the more uniform distribution of stress results in a higher strength. Lessons like this illuminate our understanding of materials in general.

Another area where work with different materials has interacted is in the statistical problems of failure. Lawrence Balls—one of the first great technologists of the cotton industry—appreciated the 'weak-link effect' in determining the strength of cotton yarn. Then, in 1929, Peirce at the Shirley Institute treated the problem statistically, dealing both with the series problem of a sequence of elements of differing strength and the related parallel problem of a bundle of threads. As one follows the subject, the contributions come from Weibull and Irwin on metals, leading into the whole problem of fatigue in engineering materials; from Spencer-Smith again on textile yarns, dealing with the effect of correlation in strength between neighbouring elements; from Coleman on fibres and polymers, taking account of the time-dependent effects; and from Freudenthal and Gumbel in their work on extreme value statistics, which demonstrates the relevance of the problem in any technological field where one is interested in the rare occurrences at one end of a frequency distribution. Work on cotton yarns could become relevant to work on the interruption of radio control in space: the statistical problems are similar. The intensity of interruption varies from hour to hour, day to day, and year to year as a result of the superposition of several regular and random effects: the variation of thickness of strength of a yarn along its length similarly results from a superposition of different effects.

**Polymers and metals; glasses and liquids.** Ten years ago most scientists concerned with either material would have said that polymers and metals were as different as the proverbial 'chalk and cheese'. But last summer Malcolm Williams of Chemstrand Research Center opened a lecture at the Massachusetts Institute of Technology by presenting pairs of slides, and inviting the audience to decide which were from metals and which were from crystalline polymers. There was close similarity in the morphological forms shown in electron micrographs and in the shape of curves of mechanical properties. The link between the two is the way in which crystallization occurs. The chief determining factors in crystal growth are the critical size of nuclei, the tendency to minimize free energy, and the mass and heat transfer in the region of the growing crystal. These are general effects and they result in similar forms. If crystallization starts in several places we get a domain structure. Imperfections appear as defects and dislocations in the crystal. On applying a force, there is first a small elastic deformation of the crystal itself; but then, as the force builds up, the defects start to move through the system, like a ridge being pushed along in a carpet; crystal planes slide over one another, and we get yielding and permanent deformation. This happens in the drawing of films, metals, and fibres.

The polymer scientist used to think of crystalline polymers as composed of small crystalline regions embedded in a non-crystalline matrix, and consider the deformations of the two parts separately. Now he is realizing that it is also possible to think of materials in the same way as the metallurgist, and consider polymers as a continuous crystalline material loaded with defects. Of course, the behaviour of metals and polymers is not identical: in polymers the atoms are connected in long chains, and this both influences the type of movement which is possible and is likely to lead to larger regions of disorder. Consequently there is still value in the older ideas, as well as the newer ones coming in from metallurgy.

While crystalline polymers have much in common with metals, the examination of the technology of amorphous polymers will benefit from work on glasses and liquids.

The extent to which there is some degree of order in these systems is an important unsolved problem. This in turn reacts on the behaviour of crystalline materials, since the existence of order in the melt will influence the detailed structure of the crystalline solid which is formed. An understanding of the behaviour of a wholly amorphous material may also be a help in understanding more complicated polycrystalline materials: investigations of the cold-drawing of amorphous polymers such as polystyrene are being carried out as a lead to the understanding of drawing of synthetic fibres.

**Fibrous systems.** In living organisms, fibres are of great importance: nerves, muscle fibres and tendons all help to make the body work. Man has long utilized fibres in textiles and paper. Fibres are strong and flexible—two properties which are often opposed, for if you strengthen a structure you usually make it more rigid. In a well-designed fibre system, you can allow the fibres to act independently to give freedom of movement, but cause them to combine to resist rupture.

The flexibility of fibres is to be expected, because they are so fine, sometimes less than ten wave-lengths of light in diameter; but their strength is greater than might be expected. Whereas sheet glass has a strength of about 2,000 lb./in.<sup>2</sup>, commercial glass fibres are nearly a hundred times stronger, and carefully prepared undamaged glass fibres break at 500,000 lb./in.<sup>2</sup>. This is due to the critical dependence of strength on cracks and other flaws—you cannot have a deep crack in a fibre!

Consider a bundle of 1,000 glass fibres. If one fibre is broken, the strength is reduced by 0.1 per cent; but a comparable crack in the surface of an equivalent glass rod would cause a catastrophic drop in strength. Furthermore, if there is some cohesion, due to friction or a binding material between the fibres, then a fibre which is broken in one place will contribute to the strength elsewhere. The degree of cohesion has to be right: if it is too strong, the stress concentration will not be prevented, and the advantages of the fibrous system will be lost, while if it is too weak the whole fibre will slip.

The best-known practical realization of strong fibre-reinforced systems is in reinforced plastics: cotton or paper in phenolic resins, and fibreglass in polyester resin. The plastics technologist is likely to be faced with a choice between woven and knitted fabrics, and with the other complexities of textile and paper technology.

Now there is also an interest in fibre-reinforced metals. Rolls-Royce, for example, are investigating aluminium-coated quartz fibres which can be pressed up into blocks. They are having to solve the problems of melt spinning, just like any other fibre producer. Others are investigating the possibilities of single crystal whisker fibres.

Apart from all the incidental mixing of technologies which comes from the use of fibres in constructional materials, there is the fundamental problem of how fibre-reinforced materials behave. Their technology is not yet well understood. The commercially successful reinforced plastics have been produced by empirical trials, rather than designed on the basis of rational understanding. Theoretical and experimental investigation of a variety of systems is needed.

There is a wider unifying subject here in the structure and mechanics of fibrous systems. Wood and paper, woven and knitted textiles, cords and ropes, the new non-woven fabrics, fabrics coated with flexible thermoplastics, thermo-setting resins or metals reinforced with inextensible fibres, and concrete toughened by the addition of nylon fibres are all different systems; but there are analogous problems in the geometry and statistics of fibre arrangement and in mechanical, electrical, thermal, diffusion and optical behaviour. The acquisition of a facility in dealing with all the systems will come from studying them together.

**Problems of scale.** There are other useful analogues where the scale of a system is changed. Scale down a

fibre assembly a thousand times and you have an assembly of polymer chain molecules; scale it down a hundred times, and you have the fine fibrillar structure which often occurs when polymers crystallize; but scale it up a thousand or more times and you have concrete reinforced with metal wires or rods.

Theoretical or experimental results can be taken over, with care, from one problem to another. The understanding of rubber elasticity helps our understanding of non-woven fabrics. The well-proved analysis of the mechanics of twisted yarn has been applied in an analysis of the mechanics of single plant fibres.

**Rheology and dynamic behaviour.** Mechanical properties are dependent on time. This is always true, though it can be ignored when an elastic deformation is so much more rapid or a viscous deformation so much slower than the time scale of ordinary events. In the many circumstances where time cannot be ignored, the subject of rheology brings together a diverse collection of scientists and technologists. The basic mathematical and experimental methods are the foundations of the subject; but the superstructure spreads out into metallurgy, polymer technology, oil technology, lubrication, adhesion, papermaking, textile technology, geophysics, physiology and medicine, soil mechanics, and other applications.

We find in this subject, too, a link between mechanical and electrical properties of materials. The swinging of dipoles into alignment with an electric field is a mechanical action. So the dynamic response of a material to an alternating electric signal has very close similarity to the response to an alternating stress. Dynamic compliance (the reciprocal of modulus) is analogous to dielectric constant; mechanical creep is analogous to the build-up of electric polarization; and the effect of temperature in loosening up a structure is similar.

The experimental problems of rheology also tax the ingenuity of the electronic engineer, so that we find one of the most important schools of the rheology of liquids in a school of electrical engineering. Other schools are in mathematics, physics, or chemistry departments as well as in many technological departments.

**Dynamics of processing.** It is one thing to investigate materials in the laboratory, or even to examine them in use: it is another thing to examine their behaviour in processing. Speed is then all-important. Polymer crystallization may take hours or weeks in the laboratory, but the man-made fibre being extruded in the factory moves through the crystallization zone at a high speed. A drill pierces metal in a fraction of a second. Large volumes of material flow through pipes at high speed.

In all these situations, the dynamics of processing must be considered. Consider the first example of the production of a man-made fibre. As it emerges from the spinneret, we have first the rheological problem of flow in a viscoelastic medium—within the tube the molecules are oriented, but on emerging they spring back to a disoriented form, and we get a contraction, a bulging, and a reduction in velocity. Then we get problems of hydrodynamics and aerodynamics, as the flow accelerates under gravity but is retarded by the drag of the surrounding gas. All the time, we have a heat-flow problem as the specimen cools; this leads to change in viscosity, and ultimately to solidification and perhaps to crystallization. Finally, there is the mechanical problem of winding up the yarn. If we want to take any measurements during the process, we are immediately led into complex problems of instrument engineering—how do you determine the temperature of a rapidly moving molten threadline, a few microns in diameter? If we want to control the process, we have the problems of control engineering. Can the technology of man-made fibre production possibly be studied in isolation?

The same comment could be made about many chemical engineering and mechanical engineering processes. The

dynamic problems inevitably bring in aspects of many technologies.

*The textile industry.* As final examples, we take two more limited topics. The first is the textile industry—or should it be industries? It used to be. Spinning, weaving, knitting, and chemical finishing were all examined separately. Individual companies had a very narrow range of operation: they often dealt with only a specific aspect of processing of one type of fibre.

This has changed now; the textile technologist must know the whole field. He must be able to select the fibres, and determine the sequence of operations from fibre to finished product. Here we see not so much the interaction of technologies as the merging of several technologies into one, and with the non-woven fabrics coming very close also to paper technology.

*Tyre-cords: a choice of materials.* The other example concerns a choice between materials in a large industrial market with fairly clearly defined requirements. For use as tyre-cords there is a choice between cotton, rayon, nylon, polyester fibre, fibreglass, and steel. All are being used—the natural fibre, the regenerated fibre, the synthetic fibres, the glass, and the metal. This is an example of interaction by competition in use. The user must look at all the technologies; the supplier must watch the technology of his competitors.

Cotton used to be the material used, but in the 1940s it was replaced by rayon, except in bicycle tyres. Then nylon challenged rayon, and there is still a nicely poised balance of technical and economic factors. Incidentally, the strength of rayon tyre-cords has been almost doubled in advances over a period of ten years, due to this competition. So far, the competition was within the textile industry, but with steel wire the competition came from outside textiles. Courtaulds hedged by acquiring a company supplying steel for this purpose! The technological and economic arguments about the different materials go on.

*Advantages of interaction.* In this article, it has been shown how the materials technologies interact with other technologies in use, and in the methods used to process materials. These interactions are fairly obvious. The

user has to handle many materials; and there is competition between materials from very different sources.

Less obvious is the value of interaction between the scientific studies of different materials. Work on other materials can be a useful source of ideas; and sometimes a detailed analysis can be taken over. But perhaps the most valuable general feature is that a comparative investigation of different materials enables the specific to be separated from the general. It is all too easy in dealing with a particular material to attribute phenomena to specific features: to ascribe the characteristic draw-ratio in synthetic fibres to some particular molecular transformation, whereas it is merely a result of adiabatic extension of material with a certain, common form of load-extension curves; or to attribute particular oblique lines of fracture to a particular crystal structure instead of to a stress distribution which would occur in all specimens of the same shape. Luder's bands, first found in metallic fracture, have reappeared in the literature of the fatigue failure of fibres. Or again, changes which were found in the nature of break of reinforced metal specimens as the specimen length was changed were found to be similar to effects which had been previously reported for textile yarns.

By examining the behaviour of a variety of materials, we can build up a coherent body of knowledge in place of an empirical compendium of unrelated facts. We now have the necessary scientific basis, though the complication of applying it to the behaviour of real materials—so different from the abstractions and specially simple examples beloved by the pure physicist—should not be underestimated. On the more practical side, there is much to be gained from collaboration and exchange of ideas in processing methods—cutting, moulding, drawing, forming, and so on—and in instrumentation and control. As the use of materials becomes more and more a rational technology, and less pure industrial empiricism, the benefits of interaction among the materials technologies and with other technologies will grow. For this reason it is encouraging that materials scientists and technologists are increasingly co-operating in various centres and societies, so that the barriers between the technologies are coming down.

## FUTURE OF THE TRISTAN DA CUNHA ISLANDS

By DR. N. M. WACE

Department of Geography, University of Adelaide

THE plant and animal life of remote islands has long been considered of unusual interest, especially since the classical investigations of Charles Darwin in the Galapagos group<sup>1</sup>. To the earlier explorers, the insular forms of life were matters mainly of curiosity and unco-ordinated speculation; but since the publication of Darwin's *Origin of Species*<sup>2</sup> and Alfred Russel Wallace's *Island Life*<sup>3</sup>, it has been widely accepted that island biota present features of outstanding biological, evolutionary and geographic interest. Much attention has therefore been paid to investigations of the plant and animal life in many remote islands, especially in Hawaii<sup>4</sup>, Juan Fernandez<sup>5</sup>, and the Galapagos<sup>6</sup> and other Pacific archipelagoes<sup>7</sup>, and also in Macaronesia and in the islands of the Indian and Southern Oceans<sup>8</sup>.

Wallace<sup>9</sup> emphasized the devastating effects of the introduced goats on the native vegetation of St. Helena, and a continuing and increasingly important theme of later workers on islands has been the very marked impact of man and his associated plants and animals on the indigenous insular ecosystems<sup>10</sup>. Simpson<sup>11</sup>, in discussing islands as "evolutionary traps and blind alleys", considered that man and the organisms introduced by him have caused more extinction of native species on islands

than on continents. Elton<sup>12</sup> discussed the reasons underlying the sudden changes induced by man, and a recent symposium<sup>13</sup> has been devoted largely to a discussion of man's impact on Pacific islands, and ecological and economic consequences of the rapid changes that he has initiated in them. The instability of island ecosystems is thought to be due chiefly to the small size, lack of diversity and consequent ecological disharmony in their native floras and faunas; the presence of unexploited niches in their ecosystems; and the lack of refugia, and hence of buffering effects on the biota against environmental changes. Introduced herbivorous and predatory mammals, as well as the direct felling and clearing of vegetation, seem to have been the most effective agents used by man in disrupting many island ecosystems<sup>14-16</sup>. Most of the remote temperate and tropical oceanic islands of the Atlantic have long been settled by man, or have been greatly altered by goats and other grazing animals introduced since their discovery by Europeans in the sixteenth and seventeenth centuries<sup>17</sup>.

The temperate and tropical oceanic islands of the Indian Ocean either support large and rapidly increasing human populations which have exterminated much of their indigenous biota<sup>18</sup>, or have been much altered by

the introduction of herbivores<sup>14</sup>. The native biota of all the low-latitude Pacific islands has been to some extent disturbed by pre-European man, except for Juan Fernandez and possibly the Galapagos<sup>15</sup>; but both these groups and almost all the remote 'high' islands of the Pacific have suffered radical alterations to their biotas since their discovery and exploitation by European man<sup>16</sup>. Even the remote islands of higher latitudes in the Southern Ocean which have proved too inhospitable for permanent human settlement have not escaped the introduction of mammals such as rabbits, which are having a profound effect on their native ecosystems<sup>14</sup>.

The four volcanic islands of the Tristan da Cunha group in the mid-South Atlantic (37°–40° S., 10°–12° W.) were uninhabited by man when discovered by the Portuguese in the early sixteenth century<sup>11,12</sup>. Although populations of seals on all four islands were destructively exploited during the late eighteenth century, and Tristan main island supported a human population from 1810 until its evacuation following the volcanic eruption there in 1961, the smaller islands in the group remain substantially unaffected by human activities. Because of their inhospitable climate and terrain, and their remoteness from shipping routes following the advent of steam propulsion at sea and the cutting of the Suez Canal, the islands have largely escaped the later human attention that has characterized almost all other tropical and temperate archipelagoes.

In their present state, the Tristan da Cunha islands therefore represent something unique and of great scientific interest: a group of remote but ecologically diverse oceanic islands in temperate latitudes, with a substantial native flora and fauna in which the pre-human ecological *status quo* is still very largely preserved.

Following the Royal Society Expedition to Tristan da Cunha in 1962, the islands have recently been the subject of a series of geological and biological papers which summarize the present state of knowledge concerning their geological origin<sup>13,14</sup>, and the composition, age, history and relationships of their plant<sup>15</sup> and animal<sup>16</sup> life. Geochemical, palaeomagnetic and geomorphic evidence all suggest that none of the islands is older than mid- to late-Tertiary<sup>13,14</sup>, and evidence of continuing volcanic activity is present in layers of volcanic ash from peat deposits which were laid down during the past few thousand years<sup>17</sup>. The native biota appears to be recently immigrant, and mostly derived from South America; it lacks the deep-seated endemism which is characteristic of the Galapagos, Hawaii, Juan Fernandez and St. Helena<sup>11,16</sup>.

The isolation which has so largely preserved the biota of the Tristan islands from disturbance and alteration at the hands of man is not likely to continue indefinitely. Since the return of the islanders in 1962 and 1963, considerable new construction has occurred and livestock imported to Tristan main island. Strategic, commercial, or other considerations could soon lead to a rapid breakdown of their isolation, with the consequent loss of much that is of unique biological interest<sup>18</sup>.

Because of the preservation of some of the islands from drastic human interference, the Tristan group presents numerous opportunities for research into problems of fundamental ecological and evolutionary interest which are not readily obtainable elsewhere. A close examination of the ecological *status quo* prior to the arrival of introduced plants and animals could contribute much to an understanding of the causes of instability in ecosystems<sup>11</sup> and its possible relationship to the degree of integration within the biotic communities<sup>19</sup>. Owing to the relative simplicity of their impoverished biota, the islands present ecological problems such as those of niche analysis and species interaction, which could more easily be examined there than in a continental setting<sup>20</sup>. Examination of the efficiency of energy fixation, nutrient cycling and gross productivity within the species-poor ecosystem would be of considerable interest for comparison with those of

climatically similar continental regions having a more diverse biota. Biometric and genetic investigations of the Tristan populations could yield much valuable information on the structure and variability of radiating taxa, and on the types of genetic system present, and could contribute to an understanding of the importance of the 'founder principle' in differentiating small immigrant populations<sup>21</sup>.

Gregory<sup>21</sup> has stressed the need for the establishment of aerospora investigations in remote islands, and the Tristan group would make an ideal site for such work. Combined with other investigations on dispersal agents, aerobiological work might also throw some light on the old and still controversial problem of the possibilities of long-range dispersal of plants and animals across wide ocean barriers<sup>22</sup>. The presence of four islands in the Tristan group, of differing ages, sizes and altitudes, adds greatly to their potential for research in these fields. Peat deposits on all of them, containing organic remains of the past five thousand years<sup>17</sup>, together with older remains which have been dated up to 40,000 years B.P. on some islands<sup>23</sup>, make it possible to carry the ecological investigations back into the recent past.

The more pronounced effects of man on some islands than on others makes possible a close examination of the alien species as they extend their range to the less affected smaller islands. An accurate documentation of the human-induced alterations in their ecosystems would be a useful contribution to the understanding of disturbances due to man, which have gone unrecorded elsewhere until the processes involved are very far advanced<sup>13,16</sup>.

The examination of these ecological and evolutionary processes in the Tristan da Cunha islands demands active conservation of their native biota. Owing to their ecological instability, and vulnerability to the effects of man, some control of human activities on the smaller islands will be essential if the scientific interest of their unique ecosystems is not rapidly to disappear. The history of insular biota elsewhere indicates that both herbivorous and predatory mammals (especially goats, sheep, pigs, rabbits; cats, dogs, mongooses and rats) must be rigidly excluded from the smaller islands, and no attempts made to clear the vegetation by firing<sup>14,24</sup>. If the usual more or less haphazard processes of exploitation and development by man are permitted in the Tristan islands, the sorry story of many of the Galapagos group, the Hawaiian archipelago, Juan Fernandez, Kerguelen, Macquarie, St. Helena and many other remote islands, will be repeated there, with the attendant disruption of established ecosystems and reduction or extinction of species, accelerated erosion, and ultimately lowered potential for biological productivity.

Stringent regulations are already in force governing the exploitation of wild life, and the introduction of alien species to the Tristan islands<sup>24–26</sup>. The importance of their observation in relation to the indigenous avifauna has been stressed by the International Committee for Bird Preservation<sup>27</sup>; but conservation experience elsewhere has shown that such regulations are difficult to enforce unless linked to a programme of research in which there is a continuing interest by biologists on the spot<sup>28</sup>. The misunderstandings which led to the importation of goats (since destroyed) to Gough Island in 1958 could easily be repeated with catastrophic results to the existing ecosystems.

If the native biota of the Tristan da Cunha archipelago is to be preserved for investigation, it will be essential to have biologists in the islands who understand the importance of and the need for conservation. This could best be achieved by the establishment on Tristan main island of a small biological research station, from which visits could be made to the other islands for investigation. The setting up of such a research station would enable other scientists with special interests in the islands (for example,

geologists, geophysicists, medical scientists, oceanographers, sociologists) more easily to work there. Instead of the usual rearguard action against commercial, military, or other interests, which so often characterize efforts at conservation elsewhere, conservation together with research could be established together as a first priority in the Tristan da Cunha Islands. The conditions for conservation are relatively simple, since active management is not needed, and it is necessary only to limit human activities and contact with the smaller islands. The conservation of the terrestrial biota and the establishment of a permanent research station on Tristan need conflict with no established commercial interests, and could at the same time become a considerable asset to the recently re-established human community, since the activities of the visiting scientists would lead to demands for both goods and services and the consequent inflow of money and employment of islanders.

The President of the Charles Darwin Foundation for the Galapagos Islands has stressed the importance of the establishment there of facilities for biological research, linked to conservation of their unique and historically interesting biota\*. The Galapagos and the Tristan-Gough group share many of the classical features of oceanic island archipelagos, which have contributed so much to evolutionary thought. They are important to ecological investigations because they provide a range of diverse but naturally simple species-poor ecosystems to be found nowhere else in the temperate and tropical regions of the globe. Although present methods of transport and the increasing demands of man constitute a threat to such vulnerable ecosystems, modern research techniques will undoubtedly allow further valuable scientific information to be obtained from them. Unless a range of undamaged oceanic islands is rigorously protected at once, the next decade may see the irreparable loss of these opportunities for research. It is greatly to be hoped that the International Biological Programme will provide an opportunity for the investigation and conservation of oceanic islands on a global scale, and that the Galapagos Foundation and a research facility in the Tristan da Cunha Islands will be only two in a world-wide network of sanctuaries and study areas.

In the formulation of their ideas on organic evolution, Charles Darwin and Alfred Russel Wallace derived much from their investigations of island life. There are therefore few more appropriate ways in which biologists might commemorate the centenary of the general acceptance of those ideas than by the promotion of research on oceanic islands such as the Galapagos and the Tristan da Cunha group.

**Note.** The Southern Zone Research Committee of the Royal Society established on October 5, 1964, a Tristan da Cunha Study Group. This group is directed to evaluate the scale of interest in research on the four islands of the Tristan-Gough group, and to assess the demand for facilities there. Circulars are being sent to scientists known to be interested in oceanic island problems and to

heads of departments and others on a rather wide scale. The group wishes to hear from anybody concerned with these matters, and correspondence should be addressed to the Convener, Dr. M. W. Holdgate, c/o the Royal Society, 6 Cornwall Terrace, Regent's Park, London, N.W.1.

## DR. WILLIAM ROXBURGH: THE FATHER OF INDIAN BOTANY

By DR. J. SEN

Indian Botanic Garden, Calcutta

THIS year marks the 150th anniversary of the death of Dr. William Roxburgh and of the publication of *Observations of the late Dr. William Roxburgh, Botanical Superintendent of the Honourable East India Company's Garden at Calcutta, on the Various Specimens of Fibrous Vegetables, the Produce of India, which may prove Valuable Substitutes for Hemp and Flax, on some Future Day, in Europe*, "edited by a friend, to whom he transmitted them

from St. Helena, during his illness; and . . . published at the expense of the East India Company, for the information of the residents, and the benefit that may arise therefrom throughout the Settlements in India" (London: 1815).

Roxburgh died at Park Place, Edinburgh, on February 18, 1815, before the small volume, *Observations*, was published later in that year. It is the first connected

scientific account of the cultivation and utilization of jute and some other fibrous plants growing in India, and is notable for the precise descriptions and presentation of results of experiments conducted by him at the Honourable East India Company's (now Indian) Botanical Garden at Calcutta.

The descriptions of the two species of jute, namely *Corchorus capsularis* Linn. and *C. olitorius* Linn., which yield fibres of commerce, are recorded by him in yet another posthumous publication in three volumes entitled *Flora Indica* (1820-32), which again is the basis of all subsequent Indian botanical works on taxonomy and floristics. This pioneering effort rightly earned for him the title of "the Father of Indian Botany", and until 1872, when the publication of Hooker's *Flora of British India* started appearing in a series, Roxburgh's was the only available single work through which a knowledge of Indian plants could be acquired. In the field of economic botany also, it was the only source of information until the publication of Sir George Watt's *A Dictionary of the Economic Products of India*, the first volume of which appeared in 1889. Roxburgh's other botanical works, particularly *Plants of the Coast of Coromandel* (in 3 volumes) and *Hortus Bengalensis*, and albums containing original paintings of Indian plants, are also well known as accomplishments of a very high order.

Roxburgh first accepted an appointment on the Honourable East India Company's Madras Establishment in 1776, and there he became acquainted with Dr. John Koenig, a pupil of Linnaeus, which no doubt influenced his subsequent work in India. He took charge of the present Indian Botanic Garden in 1793 as its first official superintendent, and with his great foresight he included both purely scientific and commercial aspects of botany in his programme. He established the great herbarium of the Botanic Garden for floristic and systematic studies of Indian plants, and at the same time started the introduction, cultivation and utilization of economic plants in India. (Most of Roxburgh's collections were distributed to the European herbaria by his successor, Dr. Nathaniel Wallich. The present herbarium was in fact made by Sir George King (superintendent, 1871-97) from the nucleus of collections started by Dr. William Griffith (Offg. superintendent, 1842-44) and developed by his successors in office. It is now the 'Central National Herbarium' of India.) Among the many plants he introduced at Samuleotta and at Calcutta, the most important are reported to be cinnamon, coffee, mahogany, mulberry,

nutmeg and pepper. It is also reported that he took an active interest in the improvement of sugar cultivation, in the rearing of silkworms and in the manufacture of silk. He left India in 1813.

Long before Roxburgh started his experiments on fibrous plants at the Indian Botanic Garden, both the species yielding jute used to be variously cultivated by local people. Roxburgh readily realized the great commercial value of jute fibres, and took up experimental cultivation of jute in the Garden, retted his produce, and measured the strength of their fibres in twisted condition before and after tanning or tarring them. Very soon he exported the first hundred tons of raw jute to Britain, and thus paved the way for the development of the jute industry in India. His untiring efforts with jute and a number of other fibres, the samples of which were sent to India House and to the Society (now the Royal Society) of Arts in London, were acknowledged by the award of the Society of Arts' Gold Medal to him on no fewer than three occasions. Many of these fibres are described in the Society's *Transactions* for 1804.

The subsequent history of the modern jute industry is another story, which, however, no doubt owes its origin to the genius of Roxburgh. Its development is a fascinating narrative told in a series of articles by Mr. D. R. Wallace in the *Empire Evening News* of Calcutta and later published as a book—*The Romance of Jute* (Calcutta: 1909), which itself has now become almost a historical document.

Near the 'Great Banyan Tree' of the Indian Botanic Garden, there is a simple monument (on the top of a small mound) to the memory of Roxburgh. The Latin inscription on the monument is by Bishop Heber, and the English rendering of the inscription (as follows) by Reverend Father Santapau written on a separate tablet was fixed last year to the slope of the mound (bearing the monument) for ready appreciation by the people of India whose debt to Roxburgh still remains immeasurable.

Whoever You Be  
If this place soothes the mind with its sweetness  
Or teaches you to think of God with reverence  
You must hold in high honour  
R O X B U R G H  
Formerly the Superintendent of these Gardens  
A man distinguished for his Botanical Science  
And most able planner  
Of rustic pleasure  
His country preserves his remains  
Here lives his genius  
May you enjoy thoroughly  
To his cherished memory his Surviving Friends  
A.D. 1823

## OBITUARIES

### Dr. A. R. Zhebrak

ANTON ROMANOVICH ZHEBRACK, a well-known geneticist of the U.S.S.R., died suddenly on May 20 at the age of sixty-three. He was also a statesman and one of the organizers of the U.N.O. as a member of the U.S.S.R. delegation to the San Francisco International Conference. As a highly educated biologist and a frank man he was a zealous champion against Lysenko. Zhebrak was therefore in disgrace for many years and died debarred from teaching genetics in the Timiriazev Academy of Agriculture in Moscow, from which he had been banished in 1948.

Zhebrak was the son of a poor peasant. As a student he rose fast during the revolution, became a student of the Academy of Agriculture in Moscow, and later a professor of genetics in his *Alma Mater*. The discovery of the inheritance of Zhebrak with crosses of wheat brought him fame and a socialist title. He was president of the Academy of Sciences of the U.S.S.R.

As a stalwart biologist Zhebrak could not reconcile himself to the absurd conceptions of Trofim Lysenko and was his energetic opponent. He was also a patriot and mourned the shame of his native land. In one of his articles in the American press he tried to demonstrate that Lysenko had given some services to the country, but that these services, and not his theories, were the reason for his rise. But unfortunately

professor of botany in the Moscow Pharmaceutical Institute. He died in this post.

Being in disgrace and having no great opportunity for his genetic works, Zhebrak continued them as a private citizen. Some of them have been published since the death of Stalin. The great merit of Zhebrak was that he, as a professor of botany in the Pharmaceutical Institute, continued to prepare new Russian geneticists as his disciples in botany. Dr. Zhebrak was a very kind, compliant, tolerant and honest man, but was irreconcilable to a falsification of science and intolerant of scientific careerists. Many young geneticists, his disciples, met near his coffin to see their beloved teacher on his last journey. Almost all the Russian geneticists were present at the funeral of their friend and companion in arms in the struggle for the scientific truth.

Anton Zhebrak lived until the time when the Russian people and its Government understood the scientific ignorance of Lysenko and the damage of his delirious conceptions for the development of science and agriculture. But the correction of old mistakes continues meanwhile very slowly. In 1948 Lysenko, as a favourite of Stalin, seized the Department of Genetics in the Moscow Academy of Agriculture and for more than sixteen years carried out his absurd genetics for young students. In March 1965 he abandoned this post, mocked and held in contempt by his students, but Zhebrak was still not returned to his old legitimate post—which is now vacant. Nevertheless, we trust that the U.S.S.R. as the country of N. I. Vavilov and A. R. Zhebrak will return to its place of honour in the field of development of scientific genetics and plant breeding.

A. KURZOW

#### Dr. A. C. Graves

DR. GRAVES, Test Division leader at Los Alamos Scientific Laboratory, died suddenly on July 29 while on holiday near Del Norte, Colorado. He was fifty-five years of age.

Dr. Graves, who most recently flew as a scientific crew member during the May 1965 Solar Eclipse Expedition in the South Pacific, had been a member of the Army Scientific Advisory Panel, and scientific adviser at the Nevada Test Site and Pacific Proving Ground since 1955. He was deputy scientific director during 1947-48, and scientific director during 1948-55 of Pacific Proving Ground operations; and test director at the Nevada Test Site during 1951-54.

Dr. Graves was one of the pioneers in the practical applications of nuclear energy. With forty-one other scientists, he helped build the world's first chain-reacting pile—the reactor in the squash court of Stagg Field in Chicago which proved, on December 2, 1942, that a chain reaction could be sustained and controlled. Ever since then Dr. Graves has been intimately associated with atomic energy work.

Dr. Norris E. Bradbury, director of Los Alamos Scientific Laboratory, said: "The tragic death of Alvin Graves

is a great loss to the Laboratory and to the world. I know it does the rest of the Laboratory and the world. He was a very kind, compliant, tolerant and honest man, but was irreconcilable to a falsification of science and intolerant of scientific careerists. Many young geneticists, his disciples, met near his coffin to see their beloved teacher on his last journey. Almost all the Russian geneticists were present at the funeral of their friend and companion in arms in the struggle for the scientific truth.

1942 until 1943 he was with the University of Chicago Metallurgical Laboratory. He joined the staff of Los Alamos Scientific Laboratory in 1943 and became head of the Laboratory's Test Division in 1948.

#### E. W. Golding, O.B.E.

MR. EDWARD WILLIAM GOLDING was born on March 9, 1902, at Northwich, Cheshire, and died at Ewell, Surrey, on June 2, 1965. He was educated at the Sir John Deane's Grammar School and at Manchester College of Technology, where he studied, as student and research scholar, under Prof. Miles Walker. He obtained his degree of B.Sc.Tech. in 1923 and that of M.Sc.Tech. in 1934. On leaving the College, he served for two years in the Research Department of Metropolitan-Vickers Electrical Co., Ltd., at Manchester, and in 1926 was appointed lecturer in electrical engineering at the then University College of Nottingham.

Specializing, at first, in electrical measurements, he later became interested in the applications of electricity to agriculture and horticulture. His investigations of these subjects were undertaken with the meticulous thoroughness which characterized all his work, and his first book, *Electrical Measurements and Measuring Instruments* (1933), now in its sixth edition, was followed by *The Electrification of Agriculture and Rural Districts* published in 1936.

He was, in those days, an enthusiastic and competent golfer, and memories of his burly figure striding purposefully around the Wollaton Park course will always remain with those who knew him there. In 1944 he was transferred from associate member to member of the Institution of Electrical Engineers, and, in 1945, he joined the Electrical Research Association as head of the Rural Electrification Section. To this post was added, in 1948, responsibility for the work of the newly established Wind-power Section. The investigation of the possibilities of large-scale generation of electricity by wind-power soon developed into a major interest which brought him into contact with people from all over the world. He became a member of the Working Group (Windpower) of O.E.E.C., acted as Unesco adviser, on problems of energy, to the Arid Zone Research Advisory Committee, and carried out missions for the United Nations and its specialized agencies in Israel, India, Somaliland, Haiti, Uruguay and Egypt.

Although Golding's writings were part of his work, they were also his main hobby and always gave him great pleasure. In 1955, *The Generation of Electricity by Wind Power* was published. This was followed by two major Food and Agriculture Organization Bulletins: *Windmills for Water Lifting and the Generation of Electricity on the Farm* and *The Potentialities for Rural Electrification in Asia and the Far East*, and a booklet, *Power Supplies*, written for the Overseas Development Institute. Throughout the years he maintained a close association with mining engineering matters and was a past-president (Midland Branch) and Fellow of the Association of Mining Electrical and Mechanical Engineers as well as being examiner for Associate Membership of the Institution of Mining Engineers. He was also a member of the Institution of Mechanical Engineers and a Fellow of both the Royal Society and the Royal Geographical Society. He was awarded the O.B.E. for his services to the mining industry in various countries, and in 1958 the duties of overseas representative were added to his other Electrical Research responsibilities. He continued to travel widely as an adviser on power supplies in remote areas and as a member of many departments in many countries, and in scientific societies, schools and universities. He was, also, a most

active participant at many international conferences and symposia, the most recent being the U.N.C.S.A.T. Conference in Geneva in 1963. In 1960 he was appointed assistant director of the Electrical Research Association, and in this capacity his broad outlook, his range of engin-

ering knowledge and his concern for the well-being of his colleagues were of great value.

He was a generous, likeable man whose passing will leave the poorer all with whom he ever came into contact.

A. H. STODHART

## NEWS and VIEWS

### Physics in the University of Sussex: Dr. D. F. Brewer

DR. D. F. BREWER has been appointed to a chair in physics in the University of Sussex. He was born in 1925, and went to the University of Oxford during the Second World War to take a shortened course in physics. He then spent three years of research in industry before returning to Oxford where he took an honours degree in 1950. For his doctoral thesis with Mendelssohn at the Clarendon Laboratory, Brewer selected work on the properties of liquid helium, a subject to which he has since devoted most of his efforts and to which he has made a great number of important contributions. He became particularly interested in the formation of the helium film from the gas phase and found that the onset of superfluidity is suppressed as the film thickness is reduced. Dr. Brewer further investigated the destruction of superfluidity by vortex formation in channels of varying diameter—research which also led to a new determination of the viscosity of the normal component. All this work was done in Oxford, some in collaboration with D. O. Edwards. He left in 1957 for Columbus, Ohio, where another of Mendelssohn's old students, J. G. Daunt, had been carrying out experiments on the properties of liquid helium-3. There Dr. Brewer was responsible in part for the discovery of the melting curve minimum and in the work on the specific heat below 1° K. He returned for three years to Oxford in 1959 where he determined the specific heat of helium-3 under pressure down to 45 millidegrees. When in 1962 the University of Sussex decided to enter the field of low temperature research, Dr. Brewer was an obvious candidate to lead it. He joined first as senior lecturer, and was appointed reader in 1964. Again the properties of adsorbed helium, now of both isotopes, became his main interest, but various other problems are being investigated in his group, which already numbers ten.

### Microbiology in the University of Sheffield:

Dr. J. R. Quayle

DR. J. R. QUAYLE, senior lecturer in the Department of Biochemistry since 1963, has been appointed to the West Riding chair of microbiology in the University of Sheffield in succession to Prof. S. R. Elsdon, who has been appointed the first director of the Agricultural Research Council's new Food Research Institute at Norwich (*Nature*, 204, 1036; 1964). Dr. Quayle graduated in chemistry at the University of Wales and later obtained a Ph.D. at the same University. On moving to Cambridge—where he obtained a second Ph.D. under the supervision of Lord Todd—his interests began to move in the direction of biology. It was, however, when Dr. Quayle went to California to work with Prof. Melvin Calvin that his transformation to a biologist came about. In Prof. Calvin's laboratory, where he made key contributions to the understanding of the enzymology of photosynthetic carbon dioxide fixation, he made his first contact with micro-organisms and with the technique of autoradiography. In his subsequent career as a microbiologist, carbon dioxide fixation mechanisms have been one of his main interests, and his use of autoradiography to elucidate metabolic pathways of micro-organisms has been a characteristic feature of his research. On returning to the United Kingdom, Dr. Quayle joined Sir Hans Krebs as a

member of the Medical Research Council's Unit for Research in Cell Metabolism in Oxford. Here he had a particularly fruitful association with Prof. H. L. Kornberg and built up an international reputation for himself in working out the metabolic pathways whereby micro-organisms elaborate complex substances commencing with substances as simple as formate or acetate as sole source of carbon. The combination of chemical expertise with a feeling for, and understanding of, living things is rare, but where it exists, as shown by Dr. Quayle's career and numerous publications, it can produce an outstanding microbiologist.

### Solid-State Physics in the Bradford Institute of Technology: Dr. D. Bijl

DR. D. BIJL, reader in natural philosophy at the University of St. Andrews since 1959, has been appointed professor of solid-state physics in the Bradford Institute of Technology. Dr. Bijl was awarded the degrees of 'candidatus' and 'doctorandus' from the University of Leiden. After the Second World War he re-started his experimental work on paramagnetic relaxation. For the latter, together with research on electron spin resonance partly carried out in Oxford during the tenure of a British Council scholarship, he was awarded a Dr.Sc. (Physics) by the University of Leiden. From 1950 until 1955 Dr. Bijl held a Pressed Steel, Ltd., Company research fellowship at Oxford. During this time he pursued two lines of research: thermal expansion of solids at low temperatures and electron spin resonance in crystals at low temperatures. His research group at the University of St. Andrews has developed work in these fields. The future main lines of research which Dr. Bijl expects to develop are in microwave spectroscopy, lattice dynamical properties of solids and semiconductor physics. For the session 1965–66 Dr. Bijl has accepted an invitation to spend a year at Massachusetts Institute of Technology as visiting professor in the Centre for Materials Research and Engineering. When he takes up his appointment at Bradford, Dr. Bijl will be responsible for the development of research and postgraduate studies in solid-state physics and for assisting in the staffing and organization of undergraduate schools.

### Medical Research Council: Advisory Boards

THE Medical Research Council is assisted in the formulation and execution of its research programme by three Advisory Boards, the Clinical Research Board, the Biological Research Board and the Tropical Medicine Research Board. These bodies have the main function of overseeing the progress of work supported by the Council and advising on proposals for such support in their respective fields, and their membership is closely integrated with that of the Council itself. Members of the Clinical Research Board and the Tropical Medicine Research Board are appointed in consultation with the Health Departments and the Ministry of Overseas Development respectively. The following appointments by the Council to the three Boards from October 1 are announced: *Clinical Research Board*, Prof. A. S. Duncan, Department of Obstetrics and Gynaecology, Welsh National School of Medicine, Cardiff, and Prof. T. Cecil Gray, Department of

Anaesthesia, University of Liverpool; *Biological Research Board*, Prof. R. A. Gregory, George Holt professor of physiology, University of Liverpool; *Tropical Medicine Research Board*, Prof. P. C. C. Garnham, Department of Parasitology and Helminthology, London School of Hygiene and Tropical Medicine, and Prof. D. V. Hubble, Department of Paediatrics and Child Health, University of Birmingham.

#### Blood Group Reference Laboratory

DR. K. L. G. GOLDSMITH, formerly deputy director, succeeded Dr. A. E. Mourant as director of the Blood Group Reference Laboratory on September 1. This Laboratory, which is administered by the Medical Research Council on behalf of the Ministry of Health, will continue to deal with all aspects of blood group work with the exception of anthropological and population surveys which will remain the responsibility of the outgoing director. On the same date, Dr. Mourant will transfer to the Council's External Scientific Staff in charge of a serological population genetics laboratory being set up by the Council. This Laboratory, which will incorporate the Anthropological Blood Group Centre (hitherto supported through a grant from the Medical Research Council to the Royal Anthropological Institute), is to be situated at Boundary House, 91 Charterhouse Street, London, E.C.1; its postal address will, however, be Serological Population Genetics Laboratory, c/o St. Bartholomew's Hospital, West Smithfield, London, E.C.1.

#### Ministerial Meeting on Science

UNDER the title "Ministers Talk about Science", a summary and review of the first ministerial meeting on science, October 1963, edited with an introduction and notes by E. G. Meethens, secretary of the ministerial meeting on science, has now been issued by the Organization for Economic Co-operation and Development (Pp. 178. Paris: Organization for Economic Co-operation and Development, 1965. 10 francs; 15s.; 2.50 dollars). Of its five parts, one is a prefatory part, in which Monsieur Lefèvre, Prime Minister of Belgium, comments on the purpose of the meeting generally, and Dr. A. King, director of the Organization for Economic Co-operation and Development scientific affairs, reviews the position of science in the work of the Organization. This is followed, in the second part, by an account of the work of the advisory group on science policy prefatory to the meeting, including the report "Science and the Policies of Government" and some discussion of the theory and practice of science policy generally. In Part 3, J. Salomon reviews the work of international scientific organizations generally, and there is a summary paper on issues of international science policy. Part 4 includes a foreword by J. R. Gass and a paper by C. Freeman, R. Poignant and I. Svernilson on science, economic growth and Government policy, covering first the economic aspects of science and next the problems of Government policy. Part 5 gives a summary of the meeting and the text of the subsequent communiqué.

#### Periodical Publications in the Patent Office Library

THE Patent Office Library is a public, open-access reference library, the use of which is freely available to all. In addition to a world-wide collection of patent specifications and patent journals, it contains 300,000 volumes of periodicals and books covering the whole field of the exact sciences and their associated technologies. The third edition of *Periodical Publications in the Patent Office Library* is a list of periodicals current at the end of July 1964, representing some 9,000 titles (Pp. v+436. London: H.M.S.O., 1965. 28s. net). This has been prepared from a visible-strip index provided in the Library, which is kept up to date by addition of new titles as they are received. In this list, which is primarily intended for use away from the Library, alternative forms

of title, especially alternative language forms, have been added, and in a few cases references have been given from alternative forms of entry for organizations. The publication is divided into five sections. The first deals with U.K. Patent Office publications, the second with the series of overseas patents, and Section 3 the overseas patent and trade-mark indexes, abstracts and periodicals. Section 4 deals with international patent indexes. Section 5, which constitutes the main part of the publication (pp. 13-436), lists alphabetically the scientific and technical periodicals held. Title entries are given if the title is distinctive; if not, the name of the issuing body is entered. The Patent Office Library does not lend its publications, but a quick postal photocopy service is provided, and this is supplemented by an immediate 'while-you-wait' photocopy service for personal callers. The basic charge is 9d. a page.

#### Physical Review

THE more frequent issue, weekly instead of fortnightly, of the *Physical Review* commenced in 1964 and the division into four volumes per annum has not proved sufficient to meet the growing demands for publication. The editors announce that it will be necessary to publish one volume per month in 1966. Because of technical difficulties, however, it will not be possible to offer separate subscriptions in smaller divisions than the present sections A and B. Starting in January 1966, each monthly volume will contain four issues and one comprehensive index issue. Each of the four issues will be devoted to one of the following specific sets of subjects in the following order: (1) atoms, molecules, plasmas; properties of atoms, ions and nuclei in solids; fluids; collective effects in solids; (2) solids (except the topics listed under (1)); (3) nuclei; (4) elementary particles; fields; relativity. The index issue will contain a comprehensive author index and an analytic subject index for all four sections. Members of the American Physical Society are offered the option of receiving (A) issues 1, 2 and index; (B) issues 3, 4 and index, or (AB) all issues. Non-members may subscribe only to all issues (AB). The editors state that it seems inevitable that more than four text issues per month will be needed in 1967.

#### The Geochemical Society of India

WITH the primary objective of fostering national and international co-operation between the geochemists and persons applying geochemical results in any field of investigation, an all-India society, to be known as the Geochemical Society of India, was established on August 20. The Society will have its headquarters at Patna, India. The following are the chief aims of the Society as contained in its statutes: "The principal objective of the Society shall be to foster the study and application of geochemistry in the national and international spheres. In pursuance of the foregoing objective the Society shall: (1) work with any interested group in planning symposia and other types of meetings that are related to geochemistry; (2) sponsor a journal called *The Journal of the Geochemical Society of India*; (3) appoint commissions and committees to study problems that require an all-India or international co-ordination". Among the chief programmes of the Society are the following: (1) All-India co-ordination of work on the Earth sciences; (2) publication of quarterly bulletins containing abstracts and summary data of work under way in India together with notes and news of important researches being carried out in the different institutions of the country as well as elsewhere.

The officers of the Geochemical Society of India are: *President*, Prof. D. N. Wadia; *Vice-Presidents*, Prof. M. S. Krishnan, Dr. A. G. Jhingran, Prof. L. Rama Rao, Dr. Hari Narain; *Treasurer*, Shri A. P. Jain (Patna); *Executive Secretary*, Dr. D. N. Ojha (Patna); *Regional*

**Secretaries**, Dr. A. N. Chowdhary (Calcutta), Dr. D. B. Sikka (Punjab), Dr. B. P. Radhakrishna (Mysore), Dr. S. K. Sen (Kharagpur); **Council Members**, Prof. W. D. West (Sagar), Prof. R. C. Misra (Lucknow), Prof. R. C. Sinha (Patna), Prof. S. N. Wakhloo (J. and K.), Prof. T. C. Bagchi (Kharagpur), Shri H. Nandi (Tatanagar), Prof. S. N. Sarkar (Dhanbad), Prof. S. K. Siddhant (Burdawan), Prof. J. N. Chatterjee (Patna), Prof. I. C. Pande (Chandigarh), Dr. P. Sinha (Patna), Prof. F. Ahmad (Aligarh), Dr. A. K. Saha (Calcutta), Shri S. P. Nautiyal (Bangalore), Dr. Sriramdas (Waltair); **Executive Editor**, Prof. R. C. Sinha (Patna), with an editorial advisory board.

### Building Research

Two important publications have recently been issued as *Building Research Station Digests*, one entitled "Protection against Corrosion of Reinforcing Steel in Concrete" (No. 59), the other "Chimney Design for Domestic Boilers" (No. 60) (London: H.M.S.O. Pp. 8 and 4d. each. 1965). The former is concerned with those factors responsible for unsatisfactory performance of reinforcing steel where corrosion occurs and indicates the requirements for depth and quality of concrete cover which must be met if this is to be avoided. The subject is briefly dealt with under headings: functions of cover, factors favouring corrosion, effects of corrosion, how corrosion occurs, prevention of corrosion, avoidance of defects in practice, materials (aggregates and special reference to chlorides aggressive to steel derived from marine deposits), construction and workmanship, preventing corrosion of steel in concrete floors, and includes examples of failed cover and spoiled appearance of concrete structures due to corrosion and spalling. In the pamphlet dealing with chimney design, emphasis is on specific requirements of modern high-efficiency domestic boilers burning solid fuel, gas or oil, if the chimney is to function satisfactorily without internal damage from effects of condensation or risk to health and safety. It is stressed that the need is "... to provide flue liners or flue blocks for appliances of the controlled combustion type ... recognized in building legislation, but satisfactory performance depends also on the sizing and thermal insulation of the flue". The important headings here are: boiler operation (all fuels), combustion, condensation and chemical attack, relative merits of air dilution and thermal insulation, and design aims.

### Flexible Urethane Foam

In an informative, illustrated article by Charles E. Petty, entitled "Changing the Form of Foam", an account is given of an established industry based on a 'happy accident' some eleven years ago (*Dupont Magazine*, 59, No. 3; May-June 1955. E. I. Du Pont de Nemours and Co., Wilmington, Delaware, U.S.A.). According to William Powers, foam division manager of the Scott Paper Company, this is what happened: "In 1954, our research laboratory was looking for a material to make household sponges. One candidate we tested was urethane foam, which has all these qualities and looks and feels like a sponge. When we tested foam's resistance to a strong caustic solution, however, the thin membrane-like 'windows' that connect its network of tiny, interconnecting strands dissolved away, leaving only a three-dimensional foam skeleton". Although this test did not actually produce the desired sponge, it did reveal the possibilities of a foam product with a highly versatile open-pore structure; such material readily permitted passage of gases and liquids, and also served as a formidable barrier against transported dirt, dust, etc. Foam is essentially 97 per cent air, the remainder being tiny interconnecting strands with enormous dust-holding capacity; it is calculated that a cubic foot of foam with 100 pores per lined inch may have as many as 2,000 ft.<sup>2</sup> of strands to

catch dirt. The basis of this flexible urethane foam is Du Pont's 'Hyleme' organic isocyanates. The article shows (in colour) some of the foam blocks of varied texture, manufactured by the Scott Paper Company. The rise in total consumption in the United States of urethane foam products is certainly impressive; since 1958, usage has risen from 10 million to 200 million pounds per annum. It is on record that while uses for Scott's urethane foam have steadily soared, an acceptable sponge has so far not been developed; "on the contrary, we looked so hard for a sponge, we came up with an open-pore product that won't even hold water".

### Guides to Mineral Exploration

A COLLECTION of articles by officers of the Geological Surveys throughout the British Commonwealth, entitled *Some Guides to Mineral Exploration*, has recently been published by the Geological Survey of Canada (Department of Mines and Technical Surveys. Paper 85-6. Edited by E. R. W. Neale. Pp. 123. Ottawa: Queen's Printer, 1965. 75 cents). The symposium was originally issued in 1964 by the Commonwealth Geological Liaison Office in London, the mimeographed papers of which have only a limited circulation; but in view of the potential value of the work to a wide circle of readers interested in the newer techniques of geological and geophysical search for ore deposits, it has been published in this more readily available form. Five of the eleven articles are by scientists of the Canadian Survey, two by those of the Overseas Geological Surveys organization in London, and one each from the Surveys of Australia, New Zealand, India and Great Britain. The collection was brought together by the Canadian geologist, Dr. E. R. W. Neale, as one of the innumerable activities undertaken during his outstandingly successful two-year term as Commonwealth Geological Liaison Officer in London, which has just come to an end. He is succeeded by Shri G. H. S. V. Prasado Rao, of the Geological Survey of India, to whom a warm welcome is assured.

### Potatoes

THE annual production of potatoes in Great Britain is about 6 million tons, of which 4 million meet the demand for human consumption and 700,000 tons are required for seed; the balance is used for stock, but there is always a considerable wastage. The potato crop is an expensive one to grow and the capital costs increase with the introduction of new machines, so that a comprehensive review from the Ministry of Agriculture, Fisheries and Food of modern techniques is welcome (Bulletin No. 94. *Potatoes*. Pp. iv + 112 + 4 plates. London: H.M.S.O., 1965. 8s. net). Every aspect of the growing and handling of the crop is dealt with by a group of specialists and the material is co-ordinated and edited by C. V. T. Dadd. The sequence is the logical one of starting with notes on the breeding, health, and certification schemes, and finishing with the regulations of marketing and the results of investigations, carried out in various parts of Britain, into the profitability of potato growing. The bulk of the Bulletin, however, is devoted to seed rates for different varieties with particulars of seed treatment, storage and sprouting, cultivations and planting and the fertilizer recommendations for different classes of soil, early potato and seed potato production, the importance of irrigation and potato spraying, methods of haulm destruction and implements for harvesting. There are also discussions on tuber quality, on storage requirements and on the preparation of potatoes for the market. There are nine appendixes concerned with useful details, and an index.

### Soil Ecology and Biology

THERE has been a Biology Commission since the founding of the International Society of Soil Science, but its work has been concerned mainly with microbiology.

However, during the past twenty years there has been a great increase in the science of general ecology based on the biology of reproduction, growth, moulting, digestion and excretion of the various groups that participate in the life of the soil. To provide a suitable means of presenting the work of investigators in this field, a new journal, with an international editorial board, was launched in 1964 (*Revue d'Écologie et de Biologie du Sol*, Tome 1, Fascicule 1, Juin 1964. Published quarterly. Pp. 1-122. Paris: Gauthier-Villars et Cie, 1964. Annual subscription 70 francs). The first volume, consisting of 3 numbers, contains 20 papers totalling 574 pages; there are 10 papers, 140 pages, in Volume 2, No. 1. Two of the papers are in English, the remainder in French.

### Scoring Virulence of Phytopathogenic Bacteria

UNDER appropriate conditions, many phytopathogenic bacteria can express virulence capacities much broader than is indicated by clinical experience. For example, passage through heterologous host plants can result in 'new' virulence characteristics. A likely mechanism would be the selection by the unnatural host plant of postulated naturally occurring virulent individuals in a statistically avirulent population—such population analysis requires a "vegetable white mouse" as a device for scoring virulence. The use of excised bean pods, under carefully specified conditions, together with genetically labelled bacterial cultures, has provided M. P. Starr and D. W. Dye of the Plant Diseases Division, Department of Scientific and Industrial Research, Auckland, with reliable, sensitive and convenient virulence-scoring techniques (*New Zealand Journal of Science*, 8, No. 1; March 1965).

### Phylogeny of the Chimaeroids

C. PATTERSON, writing from the British Museum, considers the Holocephali to be more closely related to arthrodires than to sharks and rays, although not descended from the very similar ptyctodont arthrodires, as Orvig and Stensio have considered probable, but as an independent evolution from pre-arthrodiran stock (*Phil. Trans. Roy. Soc., B*, 249, No. 757. June 10, 1965. *The Phylogeny of the Chimaeroids*. Pp. 101-219+plates 22-28. London: the Royal Society, 1965. 55s. 6d.; 8.30 dollars). The phylogeny of modern chimaeroid fishes is traced back through Mesozoic times to a Palaeozoic sub-order of the Chimaeriformes, the Menaspidoi, which possessed armour, at least to the extent of a dorsal head-shield: the balance of evidence suggests that the Chimaeriformes were derived directly from armoured ancestors with an unmodified hyoid arch, from which stock unarmoured Holocephali of the Carboniferous period, such as *Helodus* and *Chondrichelys*, would also be derived. A fairly clear picture of the head of a Lower Carboniferous menaspoid genus, *Deltopychius*, begins to emerge, partly from material previously ascribed to *Oracanthus*. Fossil remains of Holocephali, other than their tooth-plates, being rare, the microstructure of fin-spines, dermal plates and scales, and teeth provides much of the evidence. Changes in the structure of the dorsal fin-spine and in the evolution of a synchonomorial (placoid) scale from a cycломomial form are found to be parallel to changes which took place in sharks. It is held that the Devonian ancestors of the Chimaeriformes would have possessed a dermal structure like that described as *Eczenatolepis* (Mid-Devonian), which is not accepted here as ptyctodont. The point seems crucial, but this sort of histology is at present very much a specialist's subject. The section on tooth structure is important since it deals with part of the evidence from which the origin of teeth in vertebrates may eventually be understood. The criteria used seem justifiable, for example, presence or absence of pallial dentine, although the outer part of pallial dentine may become metaplastic and form part of the enameloid tissue. A diagram showing the supposed phylogenetic relationships would have helped to a more

critical understanding of this topical problem—have the aphethoid, joint-necked fishes survived in the chimaeras?—likewise a diagram showing the crown and so-called root in different durophagous fishes.

### Brain of the Pearly Nautilus

NOTHING has been known hitherto of the fine structure of the brain of *Nautilus*, and Prof. J. Z. Young's recent paper (*Phil. Trans. Roy. Soc., B*, 249, No. 754: *The Central Nervous System of Nautilus*. Pp. 1-25+plates 1-7. London: the Royal Society, 1965. 21s.; 3.15 dollars) will be of wide interest. The brain proves to be in many ways similar to, but simpler than, that of other living Cephalopoda (Coleoidea), but differs from the coleoid brain in the relatively small size of the optic and large size of the olfactory lobes, and of the rhinophore: the brain is a 'nose' rather than an 'eye' brain, macrosmatic rather than microsmatic. The nerves from the funnel are shown to be connected with the lateral part of the brain, where a small 'magnocellular lobe' is to be found; those from the digital tentacles, however, lead directly into the supracoesophageal cerebral centre, which also receives the nerves from the hood. The tentacles should thus be regarded as cephalic; the name 'Cephalopoda' embodies an ancient error of interpretation. The cerebral connexion of the digital tentacles is of special interest in the light of two other papers by Prof. J. Z. Young (*Phil. Trans. Roy. Soc., B*, 249, No. 755: *The Buccal Nervous System of Octopus. The Centres for Touch Discrimination in Octopus*. Pp. 27-67+plates 8-17. London: the Royal Society, 1965. 18s.; 2.70 dollars), one of which traces elegantly the series of nerve-centres of the feeding processes in *Octopus*—catching the food, poisoning, triturating and swallowing it—while, in the other, the connexion and origin of the inferior frontal system of the brain of *Octopus* are described. This system is already known to be the centre of tactile learning and is now shown to be derived in development from the feeding centres. It is thus suggested that food-discrimination is all-important in developing the learning centres of the brain in the Cephalopoda.

### International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in the *Bulletin of Zoological Nomenclature* (22, Part 3; August 13, 1965): (1) Validation of the generic name *Oacatus* Vieillot, 1817 (Aves). *Z.N.(S.)* 1647. (2) Designation of a type-species for *Anthonassa* Scudder, 1875 (Insecta, Lepidoptera). *Z.N.(S.)* 1697. (3) Suppression of the specific name *Aphelochus stoueri* Stefański, 1916 (Nematoda). *Z.N.(S.)* 1698. (4) Validation of the generic name *Amblema* Raffinesque, 1820 (Lamellibranchiata). *Z.N.(S.)* 1699. (5) Suppression of the specific names *Volva portus* Linnaeus, 1758, *V. morio* Linnaeus, 1767, *V. ruffina* Linnaeus, 1767, and *Bulla conoidea* Linnaeus, 1767 (Gastropoda). *Z.N.(S.)* 1700. (6) Validation of the specific name *Vespertilio yumanensis* H. Allen, 1864 (Mammalia). *Z.N.(S.)* 1701. (7) Suppression of the generic name *Trichogonia* Rosemeester, 1835 (Lamellibranchiata). *Z.N.(S.)* 1702. Any zoologist who wishes to comment on any of the foregoing cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S.W.7, before February 13, 1966.

### Races of Man

THE second edition of *Races of Man*, by Sonia Cole, serves as a useful guide to the methods of investigation used in the differentiation of racial types (Pp. 131+13 plates+34 figures. London: Trustees of the British Museum (Natural History), 1965. 11s. 6d.). A brief historical background is followed by descriptive chapters

on physical characteristics, genetical and evolutionary features and blood grouping. Recent advances in the field of human biology have been incorporated. The influence of environment on evolutionary change is one of the more interesting aspects of this investigation; but the rather simplified explanation about the unspecialized nature of the human body is perhaps not the entire story. One hesitates to attribute the lack of specialization entirely to man's achievement of a 'culture', which rendered unnecessary any major evolutionary alteration to his physique. The chapter on racial origins is refreshing in view of the cumbersome terminology still being advanced by some physical anthropologists. The author is surely right in suggesting that only two genera should be distinguished in the early hominids, but it would have been interesting to see the single genus line expostulated. Not everyone would accept the wide geographical range of these early hominids, but the racial and geographical range of *Homo erectus* seems incontestable. The position in the evolutionary sequence of the Great Interglacial European representatives still tends to be avoided. The emergence and appearance of *Homo sapiens* throughout the world make up the remainder, and bulk, of this useful handbook.

#### Ramsay Memorial Fellowships

THE Ramsay Memorial Fellowships Trustees have made the following awards of new fellowships in chemistry for the year 1965-66: General (British) Fellowship to Mr. Moti Lal at the University of Strathclyde; a Glasgow Fellowship to Mr. J. A. Miller at the University of Cambridge; a Canadian Fellowship to Dr. J. F. Skinner at University College, London; a Japanese Fellowship to Dr. H. Suzuki at Bedford College, London; a Spanish Fellowship to Dr. J. A. Burriel Lluna at the Imperial College of Science and Technology, London; a United States Fellowship to Dr. L. L. Ames. The Trustees have renewed the following fellowships for the same year to: Dr. R. D. Levine (General (British) Fellowship) at the University of Oxford; Dr. T. W. Dingle (Canadian Fellowship) at the University of Oxford; Mr. M. J. Baillie (Glasgow Fellowship) at the University of Cambridge; Miss Margaret Kerahaw (New Zealand Fellowship) at the University of Reading.

#### The Harkness Fellowships of the Commonwealth Fund—New York

THIRTY Harkness Fellowships of the Commonwealth Fund—New York are offered each year for study and travel in the United States. Candidates must be British subjects who are citizens of the United Kingdom or present Colonies by birth or by naturalization. Candidates must be between 21 and 32 years of age on September 1, 1966. By that date they should have a degree from a university or the equivalent in qualifications conferred by professional bodies, or an attested level of professional competence in the public service, the professions, the creative arts, journalism, business, industry, or other comparable careers. Candidates who propose an academic career must have experience of post-graduate research. The fellowships are tenable for between 12 and 21 months. Round-trip passages to the United States are provided. Emoluments include living and family allowances, travel in the United States, tuition and research expenses, and other allowances. Selection of Fellows for nomination to the Fund is at the sole discretion of the Committee of Award, which will conduct interviews at Harkness House, London, in February, 1966. Further information and details of the fellowships can be obtained from the Warden, Harkness House, 38 Upper Brook Street, London, W.1. Application, on forms provided by the Fund, must reach Harkness House before November 11.

#### University News:

#### Cambridge

THE following have been elected to fellowships at Churchill College from October 1, 1965 (Title B): Dr.

J. A. Miller, to a senior research fellowship; Dr. J. B. Gibson (Sheffield), to a senior research fellowship.

#### Belfast

THE following lecturers have been appointed: R. N. Hughes (psychology); Dr. J. T. Patterson and Dr. D. J. Stewart (agricultural bacteriology); Dr. B. G. J. Thompson (mechanical engineering).

#### Newcastle upon Tyne

THE following appointments have been made: *Professors*, Dr. R. B. Clark (zoology); Dr. P. Collison (social studies); Dr. J. Brown (psychology); *Readers*, Dr. T. Scratcherd (physiology); Dr. J. G. Buchanan (organic chemistry).

#### London

DR. S. COHEN has been appointed to the chair of chemical pathology tenable at Guy's Hospital Medical School. The following readers have also been appointed: Dr. P. G. Hall (geography, tenable at the London School of Economics and Political Science); Dr. M. M. R. Williams (nuclear engineering, tenable at Queen Mary College); Dr. H. Sawistowski (chemical engineering, tenable at the Imperial College of Science and Technology); Dr. D. W. Turner (organic chemistry, tenable at the Imperial College of Science and Technology). The title of reader in mathematics has been conferred on Dr. L. M. Hocking in respect of his post at University College.

#### Announcements

A SYMPOSIUM on "Man-made Lakes", organized by the Institute of Biology, will be held at the Royal Geographical Society during September 30–October 1. Further information can be obtained from the Institute of Biology, 41 Queen's Gate, London, S.W.7.

THE fourteenth autumn meeting of the Society for Water Treatment and Examination will be held at Leamington Spa during September 29–October 1. Further information can be obtained from Mr. A. W. H. McCanlis, 41 Carshalton Road, Sutton, Surrey.

A SYMPOSIUM on "Management in Research Organizations" will be held at the Manchester College of Science and Technology on September 29. Further information can be obtained from the Registrar, Manchester College of Science and Technology, Manchester 1.

A SYMPOSIUM on "Genetic and Environmental Factors in Human Ability", arranged by the Eugenics Society, will be held in University College, London, during September 30–October 1. Further information can be obtained from the General Secretary, the Eugenics Society, 69 Eccleston Square, London, S.W.1.

THE second international symposium on "Inhaled Particles and Vapours", arranged by the British Occupational Hygiene Society, will be held in Cambridge during September 28–October 1. Further information can be obtained from Dr. J. S. McLintock, Medical Services, National Coal Board, Hobart House, Grosvenor Place, London, S.W.1.

FORATOM (Forum Atomique Européen) Congress 1965 will be held at Frankfurt-on-Main during September 29–October 1, and will consist of a discussion meeting dealing with the subject "Nuclear Energy in Europe—from Raw Material to Electricity Grid". The state of development and future prospects of the use of atomic power for energy supply in Europe will be surveyed and there will be four sections dealing with, respectively: fuels, including uranium sources and fuel elements; present types of nuclear power stations; use of the nuclear power station in the electricity grid; and conclusions concerning the future utilization of nuclear energy in Europe. Further information can be obtained from Foratom-Congress 1965, 5300 Bonn an Rhein, Koblenzer Strasse 240.

## CONSERVATION OF BROADLAND

AN adjournment debate in the House of Commons on July 12 on the Broads as a national park was initiated by Mr. J. Parker almost simultaneously with the publication of the Nature Conservancy's *Report on Broadland*\*.

The *Report* was referred to both by Mr. Parker himself and Mr. B. Hazell, while in replying on the debate Mr. A. Skeffington, the Joint Parliamentary Secretary to the Ministry of Land and Natural Resources, said that the Ministry welcomed the *Report* as stimulating, knowledgeable and imaginative and that he was studying it with great interest. Mr. Parker re-opened the question of clearing the Broads of weeds, which ten years ago he had estimated would cost about £1 million. He pressed for a positive policy with regard to the Broads in the interests of both holiday makers and residents in the area, and hoped that it would be possible to interest the new University of East Anglia in the problems of the area, and to encourage it to assist in research. Mr. Hazell also referred to the need for such a policy, quoting the Strategic Plan for Broadland stressed in the Nature Conservancy's *Report*. Mr. Skeffington agreed that it was essential for the whole future of the countryside and the future of this area to be viewed afresh in the light of a rapidly changing situation, including a considerable increase in population and a great increase in mobility. He said that the Minister was making a thorough and comprehensive review of all the problems associated with the countryside and admitted that this was much overdue, and that the present expenditure of £43,000 by the National Parks Commission under the Act was derisory. The review being made at present would consider not only the needs of the parks already designated but also of possible future parks, which would be areas of recreation calling for greater accessibility than required in the national parks themselves. This review was substantially completed and the Minister hoped to reach a conclusion on this shortly. Finally he admitted that the problem was urgent and that, as the Nature Conservancy's *Report* stated, time was not on the side of Broadland and to do nothing would be to abandon the region to erosion, conflict and decay.

The Nature Conservancy's *Report* follows an earlier draft, and the recommendations now included are based on discussions on this draft. The General Survey contains the factual material, which constitutes the second chapter, and this is followed by one on present trends and another giving the Conservancy's appraisal and conclusions. Recommendations are set forth in the final chapter and these call for a basic policy to conserve and enhance the Broadland environment for holidays and for outdoor recreation as well as research and education. For holidays and such outdoor recreational activities as angling, yachting, dinghy racing, nature study and canoeing, which are essential leisurely pursuits, for research and education and for agriculture, Broadland provides a unique setting. The *Report* directs attention to the need for some understanding of the forces shaping the environment which increase the value of Broadland for basic scientific studies and biological education. Some recreational activities, both now and in the future, could be much better met in other areas, in or near large conurbations, but the total impact of existing demands on Broadland is large, and increasing. There are unmistakable signs that without positive sound policies for the long-term planning, management and development of the region many of its special features will degenerate, and much of its charm and value will be lost. Much of it is ecologically unstable and the restorative processes of

Nature cannot keep pace with the demands on them. Future policies must take full account of all these considerations and the *Report* insists on the need for a strategic plan for Broadland containing both short- and long-term features. Its detailed preparation will call for co-operative effort from many experts, and its implementation will demand full understanding at regional level and encouragement and guidance at national level. Its broad objectives must be the maintenance and enhancement of the Broadland environment; the harmonization of the activities and uses, for example, by space and time zoning; and an expansion programme involving the creation of new Broads and waterways, planned, managed and developed to meet further demands and to offer further scope for zoning. The success of the plan will require acceptance of the precept that long-term planning, management and development of the Broadland's resources of land and water and wild life must be based on research and education. The problems arising from incompatible uses are aggravated by overcrowding, which also prevents the best use being made of a given area. Accordingly, all proposals for expanding the use of Broadland must be based on an appraisal of the social and economic advantages of this use, and must be weighed against any resultant degradation of the environment. This calls for research and study to establish what the real advantages and effects of use are likely to be.

Certain steps can be taken under existing statutory powers and by negotiation, for example, in relation to pollution of the Broadland waterways from whatever source. It is recommended that appropriately constituted expert groups should be established to consider and advise on pollution, the performance of craft intended for use on the waterways, on mooring facilities, on the requirements for caravans, house-boats and 'flat-a-floats' and on a code of behaviour. Discussions between interested parties, phased as part of the plan, should also be initiated to examine the pre-requisites for increased use of those waterways at present closed to navigation or restricted in use. The full use in Broadland of existing powers to cater for the recreational activities on water should be urgently studied by the River Authorities, and discussion should be held to explore the possibilities of extending the application of zoning, both in time and space, as a means of minimising conflict between incompatible uses. Detailed consideration should be given to the practicability of creating new Broadland waterways since these would help to meet existing and future demands for more water space and also to distribute present and forecasted pressures more evenly and to facilitate zoning.

A supplement by certain members of the working party is appended in which the recommendations are based on the fact that at present no single authority can hope to identify all the facts or to provide solutions within its own powers. Accordingly, it is proposed that, as a matter of urgency, the Government should establish machinery to designate "National Recreational Areas", together with an agency to administer them and to provide facilities for outdoor recreation in the countryside generally, and that Broadland should be designated as one of these areas.

Some authority should be invested with financial resources and responsibility for preparing a long-term strategic plan and, pending the completion and adoption of this plan, this authority should seek to ensure the co-ordination and unity essential for the effective planning, management and development of the region. The Conservancy also recommends that as soon as possible a consortium be established of the planning, river, and navigation authorities with an independent chairman of standing, appointed by the Government. Meanwhile the

*The Nature Conservancy. Report on Broadland.* Pp. 98 (27 plates). (London: The Nature Conservancy, 1965.) 17s. 6d.

consortium should be empowered to implement any proposals falling within the powers of the authorities constituting it; to encourage and facilitate appropriate action by other bodies; and to develop support among other bodies and the general public for the policies and measures proposed. It should maintain close working liaison between the interests concerned and create new

facilities for the public enjoyment of Broadland within the strategy of the Conservancy's *Report*, as well as maintain constant review of trends and developments in the area and initiate action to obtain data on them. It should also detect and appraise gaps in the powers required to implement fully the agreed policies, and advise on the economic implications of these proposals.

## RADIOCHEMICALS

FOUR booklets have recently been issued by the Radiochemical Centre, Amersham\*.

The first, *Selected References to Tracer Techniques*, is a revised edition and contains a bibliography of selected publications useful to newcomers to tracer work. The contents consist of titles of general texts and articles dealing with the preparation of labelled compounds, tracer applications, methods of measurement and safety precautions.

*Radioactive Isotope Dilution Analysis* is a second edition of the booklet in which the principle of the analysis is explained and shown to be a sensitive method of determination of many substances in mixtures. It is emphasized that the technique does not require expensive laboratory facilities or materials. The application of the method is illustrated by particular examples.

Problems of radiation self-decomposition of materials are of increasing interest to users of radioactive tracer compounds, and the summary of experience gained from the storage of radioactive compounds at the Radiochemical Centre which is given in the third booklet, *The Stability of Labelled Organic Compounds*, should be very helpful. The information is largely empirical. Data for a number of compounds are listed. The essential factors in the investigation or observation of the decomposition from self-irradiation are the chemical character of the molecule which determines the liability to primary (external) and secondary effects; the purity, the solvents and diluents, the concentration, the specific activity, the temperature and other environmental conditions; and the type and

energy of the radiation from the incorporated nuclide. A detailed list of precautions in handling or storing radioactive organic compounds is included.

The fourth and most recent booklet, *Standards of Activity*, discusses the types of standard available, their certification and use. The activity of a quantity of radioactive material is defined in accordance with the 1962 report of the National Commission on Radiological Units and Measurements (ICRU) (*NBS Handbook 86*) as the number of nuclear disintegrations which occur in the quantity in unit time. The curie,  $5.7 \times 10^{10}$  disintegrations per sec, is the special unit of activity, and activity can be quoted in curies or in its sub-multiples. Activity is not constant with time but decays at a rate determined by the radionuclides present.

Because of uncertainties in purity and half-life, the accuracy to which the activity can be calculated at a given time becomes worse the longer the period from the reference time. Standards of activity have therefore an ephemeral nature and care must be taken in the interpretation of the title 'standard'. The most satisfactory physical form for a standard of activity is a solution in a flame-sealed glass ampoule, but other forms are available. Standards of activity are principally used for the calibration of measuring instruments, and the booklet makes clear the precautions to be taken if full use is to be made of the high accuracy associated with absolutely standardized solutions. In the second half of the booklet the standards available from the Radiochemical Centre are discussed and a complete schedule (operative during 1965-66) of standardized solutions together with details of their guaranteed accuracy and delivery time is given. Each of the four booklets contains a list of references.

## SCIENCE ABSTRACTS

MEMBERS of the Documentation Research Project section of the American Institute of Physics have carried out a comprehensive survey of published physics literature by a detailed analysis of the contents of the 1961 issues of *Physics Abstracts* (Section A of *Science Abstracts*). A report of the survey has recently been published\*. A total of 20,287 abstracts covering 405 periodicals from 29 countries were scrutinized, and certain details coded and transferred into machine-readable form. The method of coding used is described and illustrated by a code sheet and sample abstract. The specific codes chosen for the country of origin, the periodical, the language and the subject fields, which formed the four major fields of enquiry, are included in an appendix to the report. Each field is dealt with in detail in a separate section of the report. The greater number of papers were devoted to nuclear physics and solid-state physics. About half the articles abstracted during 1961 had been published

during that year. This may be closely related to the fact that *Physics Abstracts* uses the author abstract when available. There were twice as many author abstracts as signed abstracts. Incorporated in the report, in addition to the numerous tables of data and illustrative charts, is a reprint of an article in the *Journal of Chemical Documentation* (4, 157; July 1964), in which a description is given of an investigation of the time-lag of coverage by *Physics Abstracts* with respect to three particular periodicals. The time-lag refers to the time in months between the date of issue of the periodical in which an article appeared and the date of appearance of its abstract in *Physics Abstracts*. The three periodicals were *Physical Review Letters* (an English language journal with no author abstracts), the *Journal of Chemical Physics* (an English language journal with author abstracts for articles but not for Letters to the Editor), and *Zeitschrift für Physik* (a foreign language journal with author abstracts in English or in a foreign language). The investigation showed that the average time-lag was similar for all three periodicals, about three to four months. Many factors contributed

\* *The Journal Literature of Physics: a Comprehensive Study based on Physics Abstracts (Science Abstracts, Section A), 1961 Issues*. By Stella Keenan and Pauline Atherton. Pp. 166. (New York: The American Institute of Physics, 1964.)

to the time-lag, but the analysis indicated that the availability of author or English language abstract could reduce the time-lag by as much as one month.

*Science Abstracts*, which consists of two sections (Section A, *Physics Abstracts*, and Section B, *Electrical Engineering Abstracts*), is produced by the Institution of Electrical Engineers, in co-operation with the Institute of Physics and the Physical Society, and the American Institute of Physics. The director is D. S. Hopper, and advisory editor B. M. Crowther, formerly editor. The editor for Section A is A. Tybulewicz, assisted by seven assistant editors, and for Section B, L. MacQuisten-Wallace, assisted by five assistant editors. During 1964 the original committee of management was replaced by an advisory panel the function of which is to consider the questions of general coverage and production of the *Abstracts* and future automatic retrieval. An important conference of representatives of interested bodies, together with delegations from the United States and from the Science Research Council (then the Department of Scientific and Industrial Research), was held during October 1964. Certain important changes have already taken place in *Science Abstracts*, both in format and in price. The publication in the early weeks of this year of the 1964 author and subject indexes was a welcome surprise. The reduction in time-lag between publication of articles and their abstracts and the increased coverage more than offset the unavoidable greatly increased price. Some years ago, a larger page size and photolithographic reproduction were introduced, but it is only recently that the full advantages of these changes have been utilized. The U.D.C. classification number, which used to be attached to each abstract, was dropped some time ago without any

complaints by users, and to follow the development of physics a gradual but continuous revision of subject headings has taken place. Details of the revision and of the arrangements of entries are all carefully explained and listed in the index numbers. A notable change in the form of the author index took place in March 1965. A new style to be used in the monthly index and in cumulative indexes, which enables an entry card on which the details of an abstract is entered to be arranged easily in index order or to be used several times for different author indexes, has been introduced. A shortened form of the title of an article is used. When the article has several authors, each author's entry appears separately and all the names do not appear together in the entry, but the first author's name is followed by the sign '+' before the abstract number and the co-authors' entries with the '+' sign after their name. Commencing with Volume 68 (1965), *Science Abstracts* will publish the annual cumulative indexes in two parts, each covering a six-month period. The first parts covering the January-June issues have already appeared and the Part 2 (July-December) indexes will be issued after the publication of the December issue. Abstracts are numbered consecutively throughout the twelve monthly issues as previously.

Author and subject indexes covering the period 1960-64 for both Sections A and B are to be published during 1965. The cumulative author index for Section A, *Physics Abstracts*, contains some 240,000 entries covering 2,300 pages of text and is bound in four parts. Its publication date was May 1965. The cumulative subject index with about 370,000 entries is to follow, as also the indexes for Section B, *Electrical Engineering Abstracts*.

## SYNTHESIS OF RIBONUCLEIC ACID BY DIFFERENT REGIONS OF THE EARLY AMPHIBIAN EMBRYO

By PROF. C. H. WADDINGTON, C.B.E., F.R.S., and MRS. E. PERKOWSKA

Institute of Animal Genetics, University of Edinburgh

THE differentiation of the various regions of an embryo into a number of distinct adult cell types must involve the synthesis in each region of a characteristic battery of proteins. According to present ideas, this must necessitate the production in each region of specific messenger RNAs which 'code for' the proteins. It is also necessary that the embryonic cells should provide themselves with the protein-synthesizing machinery, such as ribosomes, with which they are initially not adequately equipped. One should therefore expect that there are well-defined differences in RNA synthesis both in time and space within an embryo. However, even in well-studied forms, such as the vertebrate egg, we are only just beginning to become acquainted with the basic facts.

The technique which was employed first was autoradiography, and it was shown<sup>1</sup> that shortly after gastrulation begins there is a regionally differentiated pattern of RNA (and protein) synthesis, which is most rapid in the organs of the dorsal axis. This synthesis occurs predominantly in the nuclei, and more specifically in the nucleoli, organelles which have long been suspected, and more recently definitely shown<sup>2,3</sup>, to be concerned with the production of ribosomes. However, the nature of the RNA detected in the autoradiographs remained a matter of conjecture. Biochemical methods have also shown that there is more rapid RNA synthesis in the dorsal parts of the amphibian embryo<sup>4</sup>, and that there are differences in the base compositions of the total RNAs of various regions<sup>5</sup>. The method of centrifugation through a density gradient, which can be used to examine the sedimentation constant

of the various RNAs, has been applied by Brown and Litt<sup>6</sup> to material extracted from whole embryos of *Xenopus*. In most of these the RNA had been labelled with phosphorus-32 incorporated into the oocyte, and available by turn-over to syntheses occurring at later stages, but in some experiments <sup>14</sup>CO<sub>2</sub> was supplied directly to embryos. Studies were made on the sedimentation patterns of RNAs extracted from whole embryos at various stages, but no attempt was made to characterize the different regions or tissues.

The main aim of our experiments was to compare the sedimentation patterns of different regions of the embryo at different stages. They therefore had to depend on the dissection of embryos so as to isolate the regions to be studied. This is bound to be a somewhat laborious task, the difficulty increasing with the precision and detail of the dissections. It was therefore first necessary to discover whether sufficient label for the purposes of sedimentation analysis could be got into the RNA of a reasonably small number of embryonic organs, such as would be practicable to dissect. It was also necessary to discover what labels could be taken up by isolated organs; in *Xenopus* substances such as nucleotides are taken up very badly if at all by uninjured embryos<sup>6</sup>.

We have worked mainly with newt (*Triturus alpestris*) embryos, although a few experiments have been made with axolotl material. As label we used uridine-5-<sup>3</sup>H (from Radiochemical Centre, Amersham, England, 24.4 c./mmole). It was found that this penetrates adequately through the cell plasma membranes which are internal to the embryo, but was absorbed very poorly in isolates

Fig. 1. Sedimentation pattern (heavy material to left) of the three regions of *T. alpestris* embryos at open neural plate stage. —, Axis; ···, ectoderm; ---, endoderm

which are completely covered with the external layer of epithelium, which carries the so-called 'coat'. The intensity of ionization obtainable from a group of explanted organs depends, of course, not only on their mass and the time of exposure to the label, but also on the activity of RNA synthesis. In the preliminary experiment conducted so far, the dissections have been rather crude, merely separating the embryos into three main regions: (a) dorsal axis, including neural system, notochord and somites; (b) endoderm; (c) lateral ectoderm including much of the underlying lateral mesoderm. Using such relatively large fragments, it was found that adequate radioactivity is obtained with no more than 6–8 dorsal pieces (from embryos from early tailbud to hatching stages) exposed to tracer for periods of as little as 2 h. Larger numbers, or longer exposures, are needed for dorsal regions of the open neural plate stage, or for endoderm pieces until near hatching, since in both these regions the rate of RNA synthesis is low. The ectoderm pieces, except from the earlier stages, are very thin, containing little substance, and considerably larger numbers would be required for study of them.

Embryos were freed from the jelly capsules with the usual sterile precautions, and dissected in one of the standard amphibian-embryo salines (Holtfreter's or Barth's) containing antibiotics (penicillin and streptomycin) as well as sulphadiazine. Motile stages were immobilized with *MS 222*, and then a little citrate (to about 0.1 per cent) was added to the dissection medium to facilitate the separation of tissue masses. After exposure to the tracer in solid watch-glasses containing about 1 ml. of medium, the fragments were rinsed in saline, and then processed without being subjected to a chase. After light homogenization, RNA was extracted by the Perry hot phenol method<sup>10</sup>. Since the quantities of RNA in the cultured fragments were not sufficient to give a reading of optical density, an adequate amount of unlabelled *Xenopus* tadpole RNA was added to the preparations, which were then layered on to a 5–25 per cent gradient of sucrose, and centrifuged in the Spinco 25.1 rotor at 2°–8° C for 16 h at 21,000 r.p.m. Fractions were collected in 30–35 tubes, the optical density taken, and the radioactivity measured on a Packard Tri-Carb scintillation counter.

Fig. 1 shows the sedimentation profiles from the three regions of 12 *alpestris* embryos of the open neural plate stage (stages 13–14 of Glaesner) labelled for 6 h. This is the earliest stage from which we have results. It is apparent that RNA synthesis is beginning to become active in the dorsal region, but is scarcely appreciable in the endoderm; in the lateral ectoderm, which was accompanied by most of the lateral mesoderm, there seems to be incorporation into RNA considerably lighter than 28 S, but we do not have results for this region in the immediately succeeding stages of development,

and the significance of this result needs further investigation. The most striking feature of the sedimentation pattern is the importance, in the dorsal region, of incorporation into RNAs which are considerably heavier than 28 S. This pattern is repeated in the dorsal regions from later stages, from tailbud to hatching. Fig. 2 shows the sedimentation patterns from dorsal regions of stages 13–14 (open neural plate, repeated from Fig. 1), from stage 20 (tailbud) and stage 27 (early muscular response). The experiments involved different numbers of embryos (6–10) and different lengths of labelling, and are thus not comparable in the vertical (ionization) scale; the sedimentation patterns have been superposed simply to emphasize the similarity in general pattern, in particular the great importance of heavy RNA.

The sedimentation pattern is somewhat different in the other two regions. In the ectoderm, as already mentioned here, the small mass of the fragments has so far prevented us obtaining clear results, but by stage 27 there is certainly incorporation into 28 S RNA, with

Fig. 2. Comparative sedimentation patterns of dorsal axis at three stages between open neural plate and early muscular response. ···, stage 13–14; ---, stage 20; —, stage 27

Fig. 3. Comparative sedimentation patterns of dorsal axis and endoderm, shortly before hatching. ---, Axis; —, endoderm

probably some formation of rather heavier material (perhaps about 35 S), but little sign of the much heavier types seen in the dorsal region. In tadpoles shortly before hatching, incorporation into the endoderm has become quite rapid. This is illustrated in Fig. 3, which compares the dorsal region with the endoderm (including the posterior part of the pharyngeal cavity). The mass of the endoderm fragments is considerably greater than that of the dorsal regions, and although the two graphs are plotted on the same co-ordinates, they are not strictly comparable quantitatively. However, qualitatively, they show that the synthesis of heavier types of RNA is much less important in the endoderm than in the dorsal axis. This observation has been made in several other experiments in which these two regions could be compared at stages just before or after hatching.

The significance of the regionally different patterns of RNA synthesis which have been revealed in these preliminary experiments remains to be elucidated. On general grounds one would expect two categories of synthesis to be proceeding: of ribosomal and of messenger RNAs. It would be anticipated that the messengers in different regions would differ in specificities, but there are no grounds on which one might be led to expect them to differ in sedimentation patterns. Concerning the ribosomal RNA, it is difficult to know what one might expect. The ribosomes of different adult tissues do not have RNAs of markedly different sedimentation characteris-

tics, and, although the existence of many DNA cistrons coding for ribosomal RNA<sup>1,2</sup> raises some question whether there may not prove to be tissue-specific differences in these substances, there is again no reason to suppose that these would show up in sedimentation patterns. However, there is evidence that the production of ribosomes may involve, as a first step, the formation of ribosomal-RNA precursors much heavier than 28 S (refs. 2, 9 and 10) and it seems likely that some at least of the heavy material in our sedimentation patterns is of this type. It is not possible to interpret the difference in sedimentation pattern between dorsal axis and endoderm until further analysis has revealed how much of the heavy RNA is ribosomal precursor, and how much messenger or DNA-like. We are planning to use the method of DNA-DNA hybridization to study this problem further.

## CHANGES IN ELECTRON SPIN RESONANCE SIGNALS OF RAT LIVER DURING CHEMICAL CARCINOGENESIS

By DR. ANTONY J. VITHAYATHIL, DR. JESSIE L. TERNBERG and PROF. BARRY COMMONER

Departments of Botany and Surgery, Washington University, St. Louis, Missouri

SEVERAL empirical observations and theoretical considerations have suggested a functional relationship between unpaired electrons, such as those associated with free radicals, and carcinogenesis. That aminoazobenzene derivatives most effective as carcinogens may form relatively stable free radicals after being assimilated into tissues was suggested by Kensler, Dexter and Rhoads<sup>1</sup>. Condensed ring compounds which have a relatively strong tendency to acquire an unpaired electron from an alkali metal, forming a relatively stable free radical, are among the more powerful carcinogens<sup>2</sup>. The carcinogenic capability of aromatic compounds may be related to a region of high electron density in the molecule, a condition which might readily occur in a free radical<sup>3</sup>.

Direct observations comparing the concentration of unpaired electrons due to free radicals of metabolic origin in normal and tumour tissues were first reported from this laboratory in 1954<sup>4</sup>. These showed, on the basis of electron spin resonance determination of frozen-dried preparations, that tumour tissue preparations yielded much smaller electron spin resonance signals than comparable normal tissues. Since then we have shown, from measurements on surviving tissues at physiological temperatures, that the electron spin resonance signal at  $g = 2.005$  normally observed in animal tissue such as liver is absent, or nearly so, in surviving tumour tissue<sup>5</sup>.

A direct examination of the relationship between chemical carcinogenesis and the free radicals observed by the electron spin resonance technique in animal tissues has now been carried out. The results reported here show that three chemically different carcinogens, soon after they are administered in the diet, cause the transitory appearance of a distinctive free radical at  $g = 2.035 \pm 0.002$ . This new electron spin resonance signal appears to be the earliest known specific response to the carcinogenic

stimulus. This generalization, if supported by observations on other carcinogenic agents, may provide a useful approach to the problem of cancer detection.

In these experiments electron spin resonance signals were obtained from 50–100 mg samples of surviving liver tissue taken from rats (male and female; Holtzman strain; 150–200 g initial weight) maintained on a semi-synthetic pellet diet. In experiments with *p*-dimethyl-aminoazobenzene (butter yellow) and thioacetamide, the experimental diet contained 0.06 per cent of the carcinogen in a feed deficient in riboflavin (1 mg/100 g diet). In experiments with 2-acetylaminofluorene (AAF) the experimental diet contained 0.06 per cent of the carcinogen in a basic mixture containing 400 mg of riboflavin and 200 mg of DL-tryptophan per 100 g. The control diets were identical with the experimental ones except for the omission of the carcinogens.

At 3–4 day intervals, animals from the experimental and control series were killed, their livers removed and stored on cracked ice for early measurement or stored in the frozen condition for later measurement. For electron spin resonance determination, 50–100 mg of liver slices were prepared, weighed and inserted into a flat electron spin resonance cell in 5 per cent glucose. Measurements were made at 15° C.

The electron spin resonance spectrometer used in these investigations is designed specifically for measurements of aqueous samples at physiological temperatures, and has been described briefly elsewhere<sup>6</sup>. The apparatus was arranged for automatically repeated sweeps of a 200 gauss field, traversed in a 16-sec period, with a modulation amplitude of 16 gauss. The intrinsic time-constant of the instrument is about 500  $\mu$ sec. All measurements were made at a constant value of  $Q$ , thereby fixing the inherent sensitivity of the apparatus. In order to enhance

the signal-to-noise ratio, a series of 50 automatically repeated sweeps were summed in half the channels of a 400-channel multi-channel analyser (RIDL model 34-12B, modified). In the remaining 200 channels a blank was recorded by entering the results of 50 repeated sweeps using the cell containing 5 per cent glucose but no tissue. This blank was automatically subtracted from the experimental signal and the result read out of the analyser by means of an X-Y recorder.

The results obtained in feeding experiments with butter yellow, thioacetamide and AAF are shown in Figs. 1, 2 and 3 respectively, together with the comparable data from control animals. All the liver samples from control animals show the electron spin resonance signal at  $g=2.005$ , half-width 20 gauss, which we have observed previously in liver tissue from a number of laboratory animals<sup>1</sup>. This signal is also present in non-tumorous liver samples from carcinogen-fed animals. However, in all three carcinogen-fed series, the livers exhibit an additional signal not observed hitherto in any normal tissue. In all three cases the new signal occurs at  $g=2.035 \pm 0.002$  and exhibits a half-width of about 20 gauss.

In all three carcinogen series, the  $g=2.035$  signal is transitory. However, Fig. 4 shows that there are striking differences in the times of appearance and disappearance of the observed signal. In rats fed on AAF, the abnormal signal appears within 7 days after feeding starts, rapidly declines in intensity, relative to the normal signal, and disappears after 12 days. When the diet contains butter yellow, the  $g=2.035$  signal makes its first appearance after 14 days of feeding, reaches a maximum intensity at about 20 days and disappears after 40 days. For rats

Fig. 1. Electron spin resonance signals from surviving liver samples from rats fed on a riboflavin-deficient diet containing 0.06 per cent of *p*-dimethylamino-azobenzene (butter-yellow), and from rats fed on a control diet lacking the carcinogen. The signals shown represent averages produced by automatic summation, with a multi-channel analyser, of 50 consecutive 16-sec sweeps through a 200 gauss field with a modulation amplitude of 16 gauss; background signals due to the glass cell being automatically subtracted. Measurements were made at an ambient temperature of  $15 \pm 1^\circ \text{C}$ , with the tissue slices suspended in a 5 per cent glucose solution. Instrument gain factors, and the amount of tissue examined (50–100 mg wet weight) varied somewhat from sample to sample so that the absolute heights of the electron spin resonance signals of different samples are not comparable.

Fig. 2. Electron spin resonance signals of surviving liver samples from rats fed on a riboflavin-deficient diet containing 0.06 per cent of thioacetamide and from rats fed on a control diet lacking the carcinogen. Experimental conditions and instrumental conditions are identical with those described in the legend for Fig. 1.

Fig. 3. Electron spin resonance signals of surviving liver samples from rats fed on a diet containing 0.06 per cent 2-acetylaminofluorene (AAF) and from rats fed on a control diet lacking AAF. Experimental and instrumental conditions are the same as those described in the legend for Fig. 1.

Fig. 4. Variation, with time after the start of the experimental diet, in the intensity of the  $g = 2.035$  signal, relative to the intensity of the  $g = 2.005$  signal in liver samples from rats fed on the three different carcinogens. The ordinate represents the ratio of the amplitude of the  $g = 2.035$  signal to that of the normal  $g = 2.005$  signal of the same sample in the data presented in Figs. 1, 2 and 3.

fed on thioacetamide, the process is even slower, the relevant times being 40, 54 and 61 days.

According to Rees *et al.*<sup>7</sup>, the time required for the appearance of liver tumours in rats fed AAF under conditions similar to those used in our experiments is about 4 months. In the case of rats fed on a butter-yellow diet similar to that used in our experiments, Miller and Miller<sup>8</sup> found that animals developed tumours in about 4–6 months. Rats fed on thioacetamide at the concentration used in our experiments developed tumours only after about 12 months or more<sup>9</sup>. Thus, the abnormal electron spin resonance signal appears, and disappears, long before tumours are in evidence.

Rees *et al.* have reported a series of histological and biochemical observations of livers of rats fed with these three carcinogens. In rats fed with AAF the histological appearance of the liver is 'relatively normal' during the first 5 weeks, although some inflammatory changes and bile duct proliferation are noted<sup>7</sup>. Bile duct proliferation reaches a maximum at 14 weeks. In rats fed on butter-yellow only minimum histological changes are observed in the first 4 weeks<sup>10</sup>. In the next 5 weeks bile duct proliferation increases progressively, and thereafter rather gross histological changes, including nuclear abnormalities, are noted. When rats are fed diets containing thioacetamide, bile duct proliferation is observable only after 6–7 weeks, and histological changes then become gradually more intense<sup>10</sup>. Biochemical investigations of the DNA and RNA contents of livers from rats fed on these carcinogens show no variations which can be correlated with the time required for appearance of tumours<sup>7,10</sup>.

From these results it is apparent that when the abnormal electron spin resonance signal which we have observed in the livers of the carcinogen-fed rats is first detected, that is, 6, 14 and 40 days for AAF, butter-yellow and thioacetamide respectively, histological changes are

minimal and non-specific. In these instances, the electron spin resonance signal at  $g = 2.035$  appears to be the earliest known unequivocal sign that the tissue is later to become tumorous.

Additional evidence that the signal at  $g = 2.035$  is specifically related to the process of carcinogenesis is suggested by the apparent identity of the signals observed in the three experimental series, both with respect to  $g$ -value and half-width. The three carcinogens used in these experiments are quite different in molecular structure; they have in common only their carcinogenic capability, and that they induce the appearance of an apparently identical free radical in the affected liver. Moreover, a series of similar diet studies on rats fed a wide variety of pharmacologically active drugs with no known carcinogenic activity, carried out by Dr. John J. Heise in this laboratory, failed to induce the appearance of the  $g = 2.035$  signal in the liver.

Preliminary efforts have been made to identify the source of the  $g = 2.035$  signal. The abnormal signal is absent from mitochondria isolated from liver of animals fed butter-yellow when the whole tissue exhibits the signal. It has not been possible thus far to observe the abnormal signal in any of the usual fractions of tissue homogenates. Unlike the normal signal at  $g = 2.005$ , which is readily observed in isolated mitochondria, the free radical which gives rise to the signal at  $g = 2.035$  does not appear to withstand the procedures involved in fractionation and isolation.

That three chemically different carcinogens induce the appearance of an apparently identical electron spin resonance signal tends to militate against the possibility that the abnormal signal is due to a free radical form of the carcinogen itself, or of one of its metabolic derivatives. As a first approximation it would appear that the  $g = 2.035$  signal is due to unpaired electrons associated with some cellular component rather than with the carcinogen or a derivative of the latter.

During the course of these experiments we were able to confirm our earlier observation that the electron spin resonance signal at  $g = 2.005$  commonly observed in normal liver tissue is absent from tumour tissue. Fig. 5 shows the electron spin resonance spectra observed concurrently from a butter-yellow induced hepatoma and from a non-tumorous region (as indicated in histological sections) in the same liver. The  $g = 2.005$  signal typical of normal liver tissue is observed in the non-tumorous region, whereas no detectable signal is present in the tumour proper. Fig. 6 shows electron spin resonance

Fig. 5. Electron spin resonance signals from tumorous and non-tumorous regions of the same rat-liver. The liver tumour was induced by feeding a rat on a diet containing 0.06 per cent butter yellow. Electron spin resonance observations were made under the same conditions as described in the legend for Fig. 1.

Fig. 6. Electron spin resonance signals from various human liver biopsy samples. All curves except the lowest one are from liver tumours. The latter represents liver sample from a patient with an undiagnosed fever. The electron spin resonance observations were made under the same conditions as described in the legend for Fig. 1.

spectra obtained from several human liver tumours of different origin. In all cases, the  $g = 2.005$  signal, which is typically present in normal liver, is absent in the tumour tissue. The same figure shows that a liver biopsy taken in the case of a non-tumour disease yields the normal signal at  $g = 2.005$ .

The results reported here show that, in the case of the three substances tested, chemical carcinogenesis is associated with certain characteristic changes in the free radicals detectable in rat liver. In all cases a signal at  $g = 2.035$ , which is not present in normal liver, appears shortly after the carcinogen is added to the diet, rises to a maximum intensity and disappears long before carcinoma is evident either grossly or microscopically. At this time the signal at  $g = 2.005$ , which is typical of normal tissue, remains; but this signal disappears when the carcinoma itself develops. Malignant tumours typically exhibit no detectable electron spin resonance signals.

These results are thus far empirical in the sense that we have no evidence as to the biochemical origin of the

abnormal electron spin resonance signal. If, as we suggest, the signal at  $g = 2.035$  is due not to a free radical form of the carcinogen, but to the generation of unpaired electrons in some structure or constituent of the cell itself, then the primary effect of the carcinogen may be on the cell's electron-transport system. Such an effect would be in accord with the concept, long under discussion, that carcinogenesis involves a transformation of cellular oxidation-reduction processes.

The present results suggest a possible new approach to the early detection of the onset of cancer. If the electron spin resonance signal at  $g = 2.035$  is an early and specific sign of later tumour formation, then it should be possible by electron spin resonance analysis of a biopsy to determine whether a tissue with suspicious but not frankly tumorous pathology is likely to later develop into a tumour. So far, this conclusion seems warranted only for the three specific carcinogens which we have studied, but with further investigations of this type it should be possible to determine whether a wider generalization—on which a diagnostic scheme for early detection of cancer might be based—is valid. Such studies are in progress in this laboratory.

## AN EARLY POTENTIAL EVOKED BY LIGHT FROM THE PIGMENT EPITHELIUM-CHOROID COMPLEX OF THE EYE OF THE TOAD

By PROF. KENNETH T. BROWN

Department of Physiology, Australian National University, Canberra

A POTENTIAL with no detectable latency was recently found in the monkey retina by Brown and Murakami<sup>1</sup>, and this response proved biphasic in form<sup>2</sup>. It was found by microelectrode methods, and identified by rigorous criteria as generated by the receptors; hence it was named the early receptor potential (RP)<sup>1-3</sup>. Higher stimulus intensities have made it possible to record this response from excised eyes by means of gross electrodes<sup>4</sup>. Investigations by this method have shown that in the pure rod eye of the rat the intervening photopigment is rhodopsin, rather than some accessory pigment<sup>4,5</sup>. Thus the early RP is an extremely rapid consequence of the absorption of light by the photopigment. The physiological significance of this response is of great interest, but is not yet determined. One question which arises is whether this type of response is unique to vertebrate photoreceptors, or whether it occurs in other cells which possess pigments for absorbing light.

A major advantage of studying isolated eyes is that the retina may be separated from the remaining eye cup, and certain variables may be controlled more readily than in eyes *in situ*. The early RP of the monkey is extremely insensitive to anoxia, and even to death of the animal<sup>1,2</sup>. During investigations of the early RP, therefore, one may use the advantages of isolated eyes without sacrificing normality of the response. Thus work was undertaken on the isolated eye of a toad (*Bufo marinus*), which is readily obtainable in Canberra. Observations on the eye cup, after removing the retina, revealed a new rapid biphasic response reported here.

In this work the animal was pitied, and the eye enucleated in normal room lighting, following which three types of preparations were made by dissection under dim red light. In one preparation a cut was made around the eye, so that the cornea, lens and ciliary body could be removed as a unit. This preparation, consisting of the eye cup with the retina, was placed on a cotton

wick electrode soaked with frog Ringer's solution. A second cotton wick electrode made contact with the vitreous humour inside the eye. In a second type of preparation the optic nerve was first shaved off with a razor blade, taking a small portion of sclera with the nerve; this freed the retina from its attachment at the optic disk. The front of the eye was then removed, and a piece of dry cotton wool was shaped to fit the eye cup and inserted into it. After a few moments the cotton adhered to the retina, which was easily removed. The cotton was then used to support the retina, which was mounted with the receptors facing upwards. The cotton was soaked with Ringer's solution, to act as one electrode, and the other wick electrode was placed in contact with the receptor surface near its centre. Microscopic examination of retinas removed in this manner showed the outer segments packed in solid array over the entire receptor surface. There was no indication that any outer segments remained with the eye cup, except perhaps at the cut edges of the retina, and no pigment cells adhered to the receptor surface. Thus the method of removing the retina provided a satisfactory separation between the retina and pigment epithelium. The third preparation was the eye cup without the retina. This preparation could be made by the procedure for isolating the retina, and a number of experiments were performed with this preparation. When the retina is removed from the eye cup, however, the remaining tissue is subject to rapid drying. Ringer's solution could be placed in the eye cup, but it quickly drained out through the hole at the optic disk. This problem was solved by leaving the stump of the optic nerve intact. After removing the front of the eye dry cotton was fitted to the eye cup. The cotton was used to pull the retina free from the eye cup, except for the attachment at the optic disk, which was carefully cut. Ringer's solution was then placed in the eye cup, which was mounted as in the case of the eye cup with the retina.

Each cotton wick electrode passed into a glass tube filled with Ringer's solution. A platinum wire was

Fig. 1. Responses from the eye cup without the retina. Records A-C are from the same preparation at increasingly faster time bases, to illustrate the time course of the response from the pigment epithelium-choroid complex. Record D is a control response from the sclera alone, after removing the pigment epithelium and choroid from the preparation. The sharp upward deflection in the lowest record shows the time of onset of the stimulus. The voltage calibration holds for records A-D; the 1 msec time calibration holds for records C and D, and for the record showing onset of the stimulus.

Fig. 2. The effects of light adaptation, followed by dark adaptation, on all three preparations. In each column record A is the first response. The preparation was then stimulated at 1-min intervals for 15 consecutive flashes, and record B is the response to the fifteenth stimulus. This was followed by a 15-min period of dark adaptation, to permit recovery from light adaptation, and record C is the first response after this period of dark adaptation. In all responses an upward deflection indicates positivity of the vitreous side of the preparation. In the bottom record of each column, the sharp break shows time of onset of the stimulus. The time calibration holds for all records. The 100  $\mu$ V voltage calibration holds for records of the left and right columns, and for the top record of the middle column. The amplitude of the response from the isolated retina decreased especially rapidly, however, and the 50  $\mu$ V calibration holds for records B and C from the isolated retina.

inserted into the solution at the other end of the tube, and that end of the tube was sealed by wax. The glass tubes were then wrapped with black tape, to avoid photoelectric artefacts at the fluid-metal junction. Discharge of the condenser in the light source caused a small electric artefact, which was recorded occasionally as a positive pip, as shown in two records of Fig. 2. This proved useful for measuring response latencies. Amplification was by a Tektronix type 2A61 differential amplifier in a type RM 565 oscilloscope. The polarity of all records was such that an upward deflection indicates positivity of the vitreous side of the preparation. The frequency response was flat from 6 to 60,000 c/s, which was sufficient to give undistorted responses.

Light flashes were provided by the condenser-discharge flash of a photographic lamp (Honeywell 'Stroboscan 650'). This lamp was mounted outside the recording room, and the light was led to the preparation by a flexible fibre optics bundle having a numerical aperture of 0.55 (Amar. Opt. type LG5-36). One end of this fibre optics bundle was placed close to the flash tube, the front cover of the lamp having been removed; the other end was placed directly over the preparation. The diameter of the fibre optics bundle was about 6 mm, which fits well to the size of the eyes examined, so an intense brief flash was delivered to the entire preparation. The timing of the flash was monitored by a solid-state photovoltaic detector (Hoffman type HA7E3), and displayed on the second beam of the oscilloscope. This detector has a rise time of about 20  $\mu$ sec, so the onset of the flash was accurately recorded, but the decay in the record appears not to reflect the true time course of the light flash. The effective exposure time of the flash is stated by the manufacturer as 0.7 msec.

Fig. 1 shows responses from the eye cup without the retina. Record A shows that the new response is biphasic in form, consisting of a rapid negative phase followed by a slower positive phase. Following the positive phase, there is no indication that there are any later portions of this response. Record B, at faster time base, resolves both phases of the response, while record C shows more clearly the rapid first phase. Record D was obtained after removing the pigment epithelium-choroid complex from the eye cup, leaving only the sclera, which was partially filled with Ringer's solution. No sign of the new response was obtained under these control conditions, or when the cotton wick electrodes were in direct contact. Thus the responses of records A-C cannot be either electric or photoelectric artefacts. The possibility was also considered that the response might not occur unless Ringer's solution was added to the

preparation. Similar but smaller responses were obtained, however, without adding Ringer's solution to the eye cup. Similar responses were also recorded, although with a higher noise level, when the wick electrodes were filled only with distilled water. Since no Ringer's solution was in contact with the preparation in this case, the new response cannot be a special type of artefact resulting from the addition of Ringer's solution. The new response was not detected from the sclera alone. But it has been detected from the isolated pigment epithelium-choroid complex, after removal of this tissue from the sclera by procedures similar to those for isolating the retina. Thus the new response must be generated by the action of light on the pigment epithelium-choroid complex.

Fig. 2 shows the effects of light adaptation, followed by dark adaptation, on all three preparations. In each column response *A* was elicited by the first flash. The preparation was then light adapted by stimulating at 1-min intervals for a total of 15 flashes, and response *B* was elicited by the 15th flash. The preparation was then left in darkness for 15 min, to observe recovery from light adaptation, and response *C* was elicited by a flash at the end of this recovery period. The response of the eye cup without the retina consistently decreased in amplitude during the period of stimulation, but this may have resulted from slight drying of the preparation. In some cases there was a small recovery of amplitude after the period in darkness, as shown in Fig. 2. But this effect was not always found, and was small in amplitude when it occurred. Thus if there is any effect of this light-adapting procedure on the new response, the effect is very small and has not been clearly demonstrated. Similar results were obtained when light adapting by flashes at 15-sec intervals. Hence the first phase of the new response is remarkably resistant to light adaptation.

In the isolated retina the first and second phases of the early RP were about equal in amplitude prior to light adaptation. By comparison with previously published records, the amplitude of the first phase is exceptionally large. Thus the isolated toad retina is a favourable case for studying both phases of the early RP in the same response. It has previously been shown that the early RP may be abolished<sup>1</sup> or reduced<sup>4</sup> by light stimulation, and in the isolated toad retina the amplitude of the early RP declined rapidly with successive flashes. The second phase declined more rapidly, however, than the first phase. After about the 10th flash the second phase was entirely abolished, but a small first phase remained, and the amplitude of the first phase was rather stable during further flashes. Thus response *B* shows the relatively stable response which could be obtained after about the 10th flash. During the subsequent period of dark adaptation, partial recovery occurred for both phases of the early RP.

The different effects of light adaptation on the early RP, and on the new response, provide a strong distinction between these two responses. It is also of special interest that the second phase of the early RP is more affected by light adaptation than the first phase. This shows that the two phases of the early RP are generated by somewhat different mechanisms. This has likewise been shown by differential blocking of the second phase of the response at very low temperatures<sup>5,6</sup>. Since light adaptation is a normal physiological type of factor, the present findings show a degree of independence of the two phases in their normal functions, as well as in their mechanisms of generation. Light adaptation also provides a convenient method for isolating the first phase of the early RP from the second phase at physiological temperatures. Previous investigations have shown that the quantitative effects of light adaptation become more marked as they are traced through the early stages of the visual system<sup>7,8</sup>. It is noteworthy that this principle holds also for the first and second phases of the early RP.

As the eye cup with the retina was light adapted, the first phase of the response decreased more rapidly than the second phase. The responses became rather stable after about the 10th flash, and in this case response *B* shows a small first phase followed by a larger second phase. Thus the qualitative effects of light adaptation on the whole preparation are superficially opposite to those on the retina alone. This is obviously due to the new response, which is not from the retina, and which strongly resists light adaptation. In this case response *B* must contain a small first phase of the early RP. But what appears to be the second phase of the early RP consists largely of the first phase of the new response. Note that the latency to the second peak of the response decreases with light adaptation, as the early RP declines and as the second peak becomes more dominated by the new response. Thus the new response is crucial for understanding the effects of light adaptation on the whole preparation.

The top half of Fig. 3 shows initial responses from the retina (*R*), and from the eye cup (*E*), which are superimposed for comparison of their time courses. When the stimulus artefact occurred in recordings of the early RP, the response was already above the baseline by the end of the artefact. Since the artefact had a duration of slightly less than 10  $\mu$ sec, the latency of the early RP is even less. This is the shortest latency measured so far, but is still a maximum value, and the rising first phase of the early RP appears to extrapolate to the leading edge of the artefact. Thus the early RP has very little or no true latency on a  $\mu$ sec scale. The new response rises just after the artefact and appears to have a true latency, although a very short one, of the order of 25–30  $\mu$ sec. It also rises somewhat more slowly than the early RP. The time from onset of the stimulus to the initial response peak is about 0.2 msec for the early RP and about 0.3 msec for the new response. The second peak of the early RP occurs about 1.75 msec after onset of the stimulus, while the second peak of the new response occurs after about 11 msec. The first phase of the new response overlaps both phases of the early RP, as shown in Fig. 3, but the second phase of

Fig. 3. The top half shows responses of the eye cup without the retina (*E*), and of the isolated retina (*R*), which are superimposed for comparison of their time courses. In the bottom half of the figure the curve labelled '*E + R*' is the sum of the separate responses, and the superimposed curve labelled '*E with R*' is a tracing of the actual response from the eye cup with the retina. The responses used in this figure are the initial responses from the three preparations of Fig. 2.

the new response is much slower than the early RP. The lower half of Fig. 3 shows the sum of responses *E* and *R*, and a superimposed tracing of the initial response from the eye cup with the retina. By comparison with the response of the retina alone, the sum of the two responses has a slightly earlier first peak, a distinctly faster fall from the first peak to the baseline, and an earlier second peak. On these aspects of the time course, the actual response in Fig. 3 fits satisfactorily to the sum of the two curves. Initial responses from the eye cup with the retina consistently showed such differences in time course from initial responses of the isolated retina. Thus the new response also accounts for these differences in time course between initial responses of the isolated retina and of the whole preparation.

In Fig. 3 the peaks of the curve '*E+R*' are not as high as those of the curve '*E* with *R*'. This comparison assumes that the responses of the retina alone, and of the eye cup without the retina, are the same as the responses when they are recorded in the total preparation. This assumption is not fully met, which has intrinsic interest. Light adaptation reduced the initial peak of the early RP more rapidly, and to a greater extent, when the retina was isolated than when the retina was in the eye cup. This is probably because recovery between stimuli was more efficient when the retina was in the eye cup. This is supported by the finding that after the 15 min recovery period the initial peak of the early RP from the isolated retina increased by a factor of only about 3, while that from the retina in the eye cup increased by about 6. This difference in recovery rates may be expected from Dowling's evidence that the pigment epithelium normally acts as a storage site for vitamin A, which is released from the photopigment during bleaching, and that this vitamin A can be returned to the receptors for regeneration of photopigment in the dark<sup>6</sup>. Because of the more efficient recovery processes, the early RP from the retina in the eye cup must be larger than that from the isolated retina. Light adaptation not only reduces the amplitude of the early RP, but in the isolated retina may be seen to slow the rate of rise and delay the initial peak. Thus the early RP of the retina in the eye cup is not only larger; it must also have a faster time course. These factors pertain even for initial responses, because of the light adaptation which occurred during dissection of the eye. These factors seem to account for the lower peaks in the summed response than in responses from the whole preparation. The departure from additivity becomes more marked during light adaptation, as may be expected. Summation of the separate responses in records *B* of Fig. 2 would not predict any appearance of the first phase of the early RP, but such a response always appeared when the retina was in the eye cup.

Previously published records by gross recording methods have all been from whole excised eyes, and some quantitative functions have been determined on excised eyes of the albino rat<sup>4-6</sup>. It is difficult to record from isolated tissues of the rat eye, because of its small size. But I have performed the type of experiment in the right column of Fig. 2 on the whole excised eye of the albino rat, with results comparable to those obtained in the toad. Responses to the first few flashes contained a prominent positive first peak, and the latencies to the first and second peaks of the initial response were about 0.15 and 1.5 msec, respectively. With light adaptation the first peak declined quickly, and in this animal disappeared entirely after the third flash. The negative second peak also declined, although more slowly; its latency decreased to about 0.75 msec, and it proved highly resistant to light adaptation. It seems evident that this negative response of the light-adapted rat eye must consist largely of the type of response found from the pigment epithelium-choroid complex of the toad eye. It has the same polarity, a peak latency which is intermediate between that of the first and second peaks of initial responses, and, most

important, a much higher resistance to light adaptation than the initial phase of the early RP.

Previous investigations have not revealed a distinct positive peak of the early RP in normal responses of the rat eye. This may have been due to more light-adapted preparations, since the first peak disappears quickly with light adaptation. In any case, this absence of the positive first peak suggests that the contribution of the early RP to the responses has been relatively small. Also the latency to the negative peak in published records is in good agreement with the latency I find to the peak of the light-adapted response from the whole rat eye. These findings make it quite likely that investigations of the negative peak of the whole rat eye have pertained largely to the new type of response. Thus it now seems required that separate investigations be conducted on the early RP of the isolated retina, and on the new response of the eye cup without the retina. In microelectrode work the amplitude maxima of both peaks of the early RP of the monkey have been found at about the level of the inner segments of the receptors<sup>8</sup>. Hence the early RP may be separated from the new response to some extent by adjustment of microelectrode depth, but even with this method the early RP is probably contaminated by the new type of response. Isolated preparations seem to offer the best solution to this problem.

Since the albino rat lacks melanin, but appears to have the new response, it is very unlikely that melanin absorbs the light which initiates this response. Thus there is no reason to expect that the new response is generated by choroidal cells. The cells of the pigment epithelium, however, contain numerous myeloid bodies in both frog<sup>10</sup> and albino rat<sup>11</sup>. These are intracellular organelles, the lamellated structure of which is typical of light-sensitive structures<sup>10,11</sup>. When the albino rat is maintained on vitamin A acid these myeloid bodies, like the rod outer segments, degenerate; both structures then regenerate on a normal vitamin A diet<sup>11</sup>. This suggests that the myeloid bodies contain a substance which is synthesized from the same isomer of vitamin A which is required for the synthesis of rhodopsin in the outer segments. Thus the myeloid bodies may contain a photopigment, either rhodopsin or a closely related substance. In good agreement with this possibility is Cone's finding that the negative peak of the rapid response from the whole eye of the albino rat has a spectral response curve similar to the absorption spectrum of rhodopsin<sup>4</sup> and that the cells of the pigment epithelium generate the c-wave of the electroretinogram<sup>12-14</sup>. The c-wave occurs in the toad eye, and is not found from the isolated toad retina<sup>15</sup>. But the c-wave has not been recorded from the eye cup of any animal after removing the retina. Discovery of a rapid response from the pigment epithelium-choroid complex of the toad suggests that the c-wave may be initiated in the pigment cells by an intrinsic photosensitivity. One wonders, in fact, whether the second phase of the response reported here may be a c-wave elicited by the brief light flash. This second phase of the new response seems too slow to compare with the early RP, and probably has a different significance.

It likewise seems especially important to know whether the first phase of the new response is generated in fundamentally the same way as the first phase of the early RP. If so, this is a type of response which is not unique to vertebrate photoreceptors, but which occurs more generally following the absorption of light by a pigment. Opposite polarities of the first phases of the two responses do not seem significant in this regard, since this could result simply from opposite orientation of the generating structures. If the two responses are fundamentally the same, the new response seems especially favourable for investigating the mechanism of generation. This is primarily because of the great stability of the response when elicited repeatedly by intense light flashes. Naming of the new response will be deferred until there is further

information on these problems of its origin and nature, work on which is now being undertaken.

## ACETYLCHOLINE RELEASE FROM THE CEREBRAL AND CEREBELLAR CORTICES: ITS ROLE IN CORTICAL AROUSAL

By Dr. J. W. PHILLIS and G. C. CHONG

Department of Physiology, Monash University, Clayton, Victoria, Australia

THE relationship between the functional state of the brain and its acetylcholine (ACh) content has been the subject of a number of investigations. Variations in the ACh level have been correlated with physiological changes in nervous activity, such as those occurring in the transition from sleep to wakefulness, or during the action of anaesthetics and convulsants<sup>1-4</sup>. In general, states of depression of the nervous system are associated with an increase in the acetylcholine content<sup>5</sup>. More specifically, the existence of a similar relationship between activity in the cerebral cortex and its ACh content has been demonstrated<sup>6</sup>, and investigations on the release of ACh into pools of eserinized saline on the surface of the exposed cerebral cortex<sup>7,8</sup> support the interpretation that increased cortical activity results in the conversion of 'bound' acetylcholine into a freely diffusible form. The mammalian cerebral cortex contains a substantial amount of choline acetyltransferase, the presence of which is largely dependent on the integrity of subcortical connexions<sup>9</sup>, and it is probable that these are constituted by the cholinesterase-staining fibres, which project from the reticular formation to the cerebral cortex<sup>10</sup>. An association between the reticular 'activating' formation and cholinergic transmission in the cerebral cortex has also been postulated as a result of pharmacological investigations on the electroencephalogram (EEG) of cats with mid-brain hemisection<sup>6</sup>.

An increase in the ACh release during peripheral nerve stimulation which was restricted to the contralateral primary somatosensory cortex has resulted in the suggestion that the cholinergic fibres to the cortex may be associated with the primary afferent pathways<sup>6</sup>, though this has not been supported by pharmacological investigations with topically and iontophoretically applied atropine<sup>11,12</sup>, which failed to block primary evoked responses.

Many cells in the cerebellar cortex are strongly excited by acetylcholine<sup>13</sup>, and the presence of cholinesterase-staining fibres in the cerebellar peduncles<sup>14</sup>, which also contain substantial amounts of choline acetyltransferase<sup>15,16</sup>, suggests that cholinergic transmission occurs in the cerebellar cortex<sup>17</sup>. It was of interest to ascertain whether ACh release also occurred from the cerebellum and to compare this with the results from cerebral cortex.

Cylindrical 'Perspex' cups, with an inside diameter of 1 cm, were held against the surface of the cortex of cats in such a manner that fluid placed within the cup could not leak out<sup>8</sup>. Several cups were used simultaneously in most experiments, distributed bilaterally on the sensorimotor, auditory and visual primary cerebral cortical areas and over the parietal cortex, covering suprasylvian and lateral gyri. Cerebellar cups were placed on the posterior vermal cortex. After placement of the cups, all exposed

cortical surfaces were covered with a 4 per cent agar jelly. The cups were filled for a period of 30 min with a mammalian Ringer-Locke solution containing  $1 \times 10^{-4}$  g/ml. eserine. They were then refilled with 0.4 ml. of fresh eserinized solution which was left in contact with the cortex for periods of 15-30 min. Samples were assayed on the heart of *Tapes virgida*<sup>18,19</sup> and some samples from cerebral cortex were cross-assayed on cat blood pressure. Pentobarbital sodium was used to anaesthetize the cats during these experiments. Four *enéphale isolé* preparations were also utilized to compare the rates of acetylcholine release from unanaesthetized preparations. The use of a highly sensitive bioassay preparation made it unnecessary to atropinize the animals before collecting ACh (see ref. 8). EEG recording from the area within the cups was by monopolar silver leads with an indifferent lead on the neck muscles, and recording screws were inserted into the bone in unexposed areas.

The results from experiments on cerebral cortex are summarized in Tables 1 and 2. Release of ACh from the unstimulated cortex was comparable in all the areas tested; this accords with the finding that the ACh content of different areas of the cat cortex is similar<sup>4</sup>. The amount of acetylcholine released could be increased by direct stimulation of the cortex underlying the cups and by stimulating a variety of peripheral afferent pathways (limb, facial and auditory stimulation). In disagreement with the results described by Mitchell, however, was the finding that peripheral stimulation caused an increase in the ACh output into all cups. Increasing the depth of anaesthesia resulted in a reduction in the release of ACh, and intravenous administration of atropine (1-5 mg/kg) was followed by an elevation in the release. Release from the cortex of *enéphale isolé* preparations into cups on the sensori-motor and parietal cortices was comparable with that from the more lightly anaesthetized cats. Atropine applied topically on three *enéphale isolé* preparations increased the mean rate of unstimulated release from 0.32 to 1.05 ng/min/cm<sup>2</sup>. Fig. 1 illustrates some of the effects on EEG tracings of eserine and atropine applied

Table 1. MEAN RATE OF ACETYLCHOLINE RELEASE FROM UNSTIMULATED CORTICES

A. CEREBRAL <i>Anaesthetized cats</i> Region:	No. of cats	Rates expressed in ng/min/cm <sup>2</sup>		
		Rate in first 30 min	Rate in second 30 min	Rate in first hour
Left sensori-motor cortex	10	0.27	0.39	0.33 ± 0.10 (S.E.)
Right sensori-motor cortex	9	0.14	0.16	0.16 ± 0.07
Auditory cortex	7	0.08	0.27	0.17 ± 0.09
Visual cortex	4	0.09	0.07	0.08
Parietal cortex	2	0.14	0.17	0.16
<i>Enéphale isolé cats</i>				
Right sensori motor cortex	3	0.45	0.45	0.45
Parietal cortex	3	0.165	0.24	0.20
B. CEREBELLAR

topically on the cortex of *enophthalis* cats. Eserine caused a decrease in the amount of synchronized activity, the EEG more closely resembling the diffusely activated pattern seen during cortical arousal. Application of atropine, in conjunction with eserine, was followed by the development of a sleep-like EEG with synchronization of cortical activity and spindling. This was associated with a failure of previously effective auditory stimuli to induce an arousal response. Intravenously administered atropine caused similar, though even more striking, changes in the EEG comparable with those that have already been described by other investigators, who have also described the dissociation between EEG and behavioural activity that is seen in the atropinized animal<sup>12-13</sup>. In cats, dogs, rabbits and monkeys, atropine induces EEG changes in the conscious animal identical with those of natural sleep (high voltage waves and bursts of spindles) and it has also been observed that atropine makes it difficult to elicit an alerting reaction even though the animal is behaviourally awake. It is evident from the effects that have been described that topically applied atropine will duplicate a substantial proportion of the phenomena which occur after intravenous administration of this drug, which are probably, therefore, the result of an action on the cerebral cortex.

The cerebellar cortex contains only approximately 1/10 of the amounts of acetylcholine and choline acetyltransferase that are present in the cerebral cortex (Phillis, unpublished observations; ref. 16), which is consistent with the finding that the amount of ACh released was proportionately reduced. A release of ACh from the unstimulated cerebellar cortex was consistently demonstrable and this was increased by direct stimulation of the surface of the cerebellar cortex.

Mitchell<sup>6</sup> has discussed the reasons for assuming that the ACh released into cups placed on the cerebral cortex actually originated from within the cortex and is not of

sub-cortical or vascular origin. A comparison of the levels of release from the cerebral cortex in the two series of experiments reveals that the rate was less by a factor of approximately 1/10 in our cats. This is probably the result of Mitchell's use of atropine to increase the level of release and thus facilitate the assay of acetylcholine, since atropine, administered intravenously in doses of 1-5 mg/kg to four cats, caused a mean increase of 0.36 ng/min/cm<sup>2</sup> in the rate of release of ACh. Peripheral stimulation through a variety of afferent pathways caused an increase in the rate of ACh release in all the areas tested. A comparison of the figures in Table 2 shows that the level of increased release was not determined by the modality of stimulation in relation to the specific primary areas involved. Forepaw stimulation caused a comparable increase in the level of release from the ipsilateral and contralateral sensor-motor cortices and from the contralateral auditory cortex. The reason for the disparity between these results and those described by Mitchell, who recorded an increase in the rate of release during forepaw stimulation only in the contralateral sensor-motor area, is not altogether clear. It was noted that high levels of spontaneous release were frequently associated with less dramatic increases during stimulation, and hence it is possible that the high levels of unstimulated release induced by atropine may have prejudiced the likelihood of recording releases during stimulation. It is also possible that atropine may have some action on the reticular formation<sup>14</sup> and that its use was associated with a block of the reticular activating system. In this case, the increase in cups over the contralateral primary somatosensory cortex could have been the result of an activation of local cholinergic circuits in the cortex by primary afferent fibres. The hypothesis that such local circuits may occur is supported by the finding that, after undercutting, 17.3 per cent of the choline acetyltransferase activity remains in the cortex<sup>6</sup> compared with the 2-4 per

Fig. 1. EEG recordings from two *enophthalis* cats. Drugs applied topically in cups over the right (RHS) cerebral hemisphere. A, Control traces: 45 min after topical eserine,  $10^{-4}$  g/ml; 30 min after topical atropine,  $4 \times 10^{-3}$  g/ml in eserine saline; 30 min after topical atropine,  $6 \times 10^{-3}$  g/ml. B, Control traces: 60 min after topical atropine,  $2 \times 10^{-3}$  g/ml; 4 min after intravenous atropine, 2 mg/kg, 3 min after intravenous sodium pentobarbital (Nembutal), 10 mg/kg. Time calibration, 1 sec.

cent in the distal portion of the sectioned peripheral nerve after a similar time-interval<sup>22</sup>.

The reason for the increased rate of unstimulated release which occurs after the administration of atropine has yet to be established, although it is probably related to the finding that atropine causes a fall in the brain content of ACh (ref. 24). Possible modes of action have been discussed<sup>24</sup>.

The widespread distribution of an increased release of ACh after peripheral stimulation suggests that the pathways subserved by cholinergic fibres must project in a diffuse manner to the cortex. It has already been suggested<sup>6</sup> that the projections of the reticular arousal system to the cerebral cortex may be cholinergic and this would be consistent with the diffuse nature of the cholinergic system described in this report. Further evidence for a cholinergic mediator in the arousal system is forthcoming from experiments on the effects of topically applied eserine and atropine on the cortical EEG. The ability of these compounds to mimic the effects of 'waking' and 'sleeping' states of the EEG, as well as to duplicate the actions that they have when injected intravenously<sup>21,22,23</sup>, suggests that a cholinergic synapse, mediating arousal responses, is likely to occur in the cerebral cortex. The results obtained with such topical applications of drugs do not allow of any interpretation as to whether the sole action of these compounds after intravenous injections is at the cortical level, or whether they also have an action in the reticular formation itself, as suggested by Rinaldi and Himwich<sup>25</sup>. It has been postulated that the effects of atropine on the cortical EEG occur at a suprareticular level<sup>26</sup>.

The results described, on the release of ACh from the cerebellar cortex, are consistent with the suggestion<sup>13,17</sup> that there are cholinergic synapses in this structure. The amounts of acetylcholine released were just above the

threshold level of sensitivity of our assay, and attempts to demonstrate an increase in the rate of release during peduncular stimulation were unsuccessful. However, an investigation of the distribution of acetylcholine-sensitive cells in the cerebellum has indicated that these occur predominantly in the depths of the cortex, and further experiments using push-pull type cannulae<sup>27</sup> are planned to analyse the amounts released at different levels of the cerebellar cortex.

## RELATIONS BETWEEN STATIONARY AND DYNAMIC PROPERTIES OF RANVIER NODES

By H. MÜLLER-MOHNSEN and O. BALK

Institut für Biologie, Gesellschaft für Strahlenforschung M.B.H., München

IN an earlier paper<sup>1</sup> we referred to our measurement of stationary current-voltage (CV) characteristics of the Ranvier node, which contains a region of negative resistance. We now try to prove that there is a relation between the stationary CV characteristic and the physiological function, that is, the action potential of the node. In electronics the function of two-electrode circuit elements is referred to their stationary CV characteristics. We have investigated whether the amplifying properties of the Ranvier node depend on its stationary characteristic.

From the electronic point of view the Ranvier node consists of an active two-electrode device which acts between a stable and metastable state. Whenever a stimulus exceeds the constant threshold amplitude, the Ranvier node turns from the stable to the metastable state. A supra-threshold stimulating impulse is amplified to a nerve signal of constant height, that is, to the 'action potential' (AP). Output energy exceeds input energy, but is independent of the amplitude of a supra-threshold stimulus (digital amplification). This function requires that the CV characteristic of the membrane includes a regenerative part with negative resistance. A characteristic like this resembles that of an Esaki diode and can indeed be recorded stationarily, like a material property, independently of the ion environment necessary for normal excitation<sup>1,2</sup>. Hitherto, the stationary negative slope characteristic has only been proved stationarily in depolarised Ranvier nodes which are no longer normally

excitable. Therefore, the following questions arise: (i) Why cannot the stationary negative slope characteristic be recorded in Ranvier nodes with resting potential? and, (ii) can the normal AP, proceeding from resting conditions, also be referred to the stationary negative slope characteristic?

The shape of the non-stationary, that is, the dynamic, CV characteristic of the membrane, measured earlier by Hodgkin and Huxley<sup>3</sup>, Tasaki and Bak<sup>4</sup> and Dodge and Frankenhaeuser<sup>5</sup>, leads to the assumption that the negative resistance is located between +10 and +50 mV relative to the resting potential, but in the region of inward current. Measuring this part of the characteristic with impressed voltage forces the membrane to a current delivery in a direction opposite to the applied voltage (metastable state). Because this active inward current, produced by the membrane, opposed in direction to the applied voltage, lasts no more than 1 msec, the negative resistance cannot be measured stationarily. Yet a slight shift of the operating range, by a depolarization of 20 mV, for example, is sufficient to permit the stationary measurement of a negative resistance, since at this time a small part (between +10 and +20 mV) of the current belonging to the negative resistance is already located in the direction of polarizing voltage relative to the new equilibrium potential. Thus, the inward current corresponds to the direction of the applied voltage and can be drawn from the external circuit. At further depolariza-

tion caused, for example, by a veratridin-containing Ringer's solution or by an increase of the extra-cellular  $K^+$ -concentration, increasing parts of a negative resistance can be recorded. At a depolarization to 60 mV almost the complete range of the negative resistance can be covered. Even though the membrane itself no longer delivers energy—because the resting batteries are discharged—it still possesses the control properties of the normal membrane. Whenever the  $K^+$ -depolarized membrane is repolarized to resting potential, that is, to its normal operating point, by an electrotonus, thus producing an outside energy source, action potentials can be released again, but with amplitudes determined by the corresponding  $K^+$ -depolarization. They are called  $K^+$ -AP.

All circuit elements with a falling OV characteristic are capable of digital amplification ('Esaki' diode, Dynatron). The shape of their output voltage can be made similar to action potentials of nerve fibres. "Depolarization and repolarization threshold" of these artificial action potentials corresponds to the beginning and the end of negative slope part of the OV characteristic, respectively, that is, to the two extreme values of the curve. The peak amplitude is given by the voltage distance between the working point and a defined point on the other branch of positive resistance. In the same way we try to correlate AP and the stationary OV characteristic of the Ranvier node shown in Figs. 1 and 2. Depolarizing stimuli cause a shift of the membrane potential to a level corresponding to a current minimum on the CV diagram, that is, the depolarizing threshold. This leads to a leap of potential into the proximity of  $K^+$  or  $Na^+$ -equilibrium potential. Thus, the metastable state is achieved, and the membrane potential decays until it reaches the value corresponding to a current maximum. A jump in repolarization direction then restores the resting potential.

The depolarization and repolarization threshold as well as the amplitude of  $K^+$ -AP can be directly referred to the stationary characteristic of the excitable membrane measured during  $K^+$ -depolarization. Since a long-lasting polarization to a value equal to  $E_{K^+}$  is not possible in myelinated nerve fibres without damaging the membrane, the characteristic underlying the normal  $Na^+$ -AP can, however, not be recorded stationarily. Thus, only indirect approaches may lead to an answer to the second question. The influence of environmental conditions altering the AP may be used to determine whether they induce at least qualitatively corresponding alterations of

Fig. 1. Changes of the stationary OV characteristic caused by acid and alkaline Ringer's solutions.  $[K^+]$  is kept constant at 40 mM/L. (node 111/68) parameter: pH;  $I_m$ —membrane current, outward current positive;  $V_m=0$  resting potential, restored by an electrotonus, crossing of the characteristics with the abscissa, that is points of zero current, indicates equilibrium potential near  $E_K$ : 33 mV. Curves 1, pH 10; 2, pH 8; 3, pH 6.

Fig. 2. Changes at the stationary OV characteristic at reduced pH,  $[K^+]$  is kept constant at 80 mM/L. (node 208/68, original curves). Curves a, pH 6-8; depolarization voltage 48 mV; b, c, d, changing to pH 4-6. b, after 1 sec; c, after 5 sec; d, after 9 sec; depolarization voltage 59 mV. (1) Depolarization threshold; (2) repolarization threshold.

Fig. 3. Changes of action potentials at reduced extracellular pH. Same preparation as in Fig. 2. (a) normal AP (84 mV) sub-threshold response 12 mV; (b) 1-3 sec after changing to pH 4-6. Sub-threshold response 42 mV, increase of repolarization threshold, compared to Fig. 2 (b); (c) after 6 sec amplitude of "AP" is continuously variable between threshold response (42 mV) and maximum amplitude (60 mV) depending on stimulus strength.

the characteristic of the depolarized Ranvier node. In this investigation we have utilized the characteristic recorded at 80 mM  $K^+$  depolarization, which covers almost the complete range of negative resistance.

First, the influence of stabilizing and labilizing conditions was investigated. Stabilizers ( $Ca^{2+}$ -rich, acid, hypertonic and  $SO_4^{2-}$  Ringer solutions) cause an increase in depolarization and repolarization threshold, while a decrease is induced by labilizers ( $Ca^{2+}$ -poor, alkali and hypotonic solutions). If the AP can really be referred to the characteristic, the stabilizers ought to cause a shift of minimum and maximum current potential toward higher depolarization voltage, while these potentials ought

to be shifted toward higher polarization voltage by labilizers. In our experiments, these alterations were found regularly; one example is shown by the alterations of the stationary CV characteristic caused by changes of pH in Fig. 1.

Further experiments were concerned with the investigation of an environmental influence of special interest. Owing to a decrease in the extracellular pH to 4.7, the region of negative resistance, that is, the transitional region between the two branches of positive ohmic resistance, is reduced by shifting the potential minimum current toward the direction of depolarization (Fig. 1c). According to the foregoing considerations the following alterations of the AP might be expected: strong increase of the stimulus threshold, of the amplitude of sub-threshold response and decrease of amplification (AP energy/threshold stimulus energy). Prolonging the action time of the acid solutions, or lowering the pH values, results in a further reduction of the transitional region, and the formerly negative resistance now becomes positive. If

there is a relation between characteristics and AP, in this phase of alteration, 'AP' with a continuously variable amplitude should occur, because the membrane no longer behaves as a regenerative system. At a pH of 4.6, the resistance in the transitional region is reduced to such a degree that it reaches the value of the high-ohmic branch. Thus, the CV characteristic of a simple rectifier appears. By then the Ranvier node should be unexcitable.

In our experiments, all these predicted AP alterations, even the variable amplitudes, could be demonstrated as is shown in the original curves of Fig. 3. They, too, were strictly reversible like the corresponding alterations of the characteristic (original curves, Fig. 2). These results lead to the conclusion that the function of the Ranvier node may be referred to the stationary membrane characteristic.

## GENETICS OF THE ALKALINE PHOSPHATASE POLYMORPHISM OF THE HUMAN PLACENTA

By DR. E. B. ROBSON and PROF. HARRY HARRIS

Medical Research Council Human Biochemical Genetics Research Unit, Galton Laboratory, University College, London

**K**INETIC<sup>1</sup>, electrophoretic<sup>2</sup> and immunochemical<sup>3</sup> investigations have shown that the alkaline phosphatase present in human placenta differs in several of its properties from the alkaline phosphatases occurring in other tissues, and suggest that the enzyme is probably peculiar to the placenta. It has also been noted that electrophoretic differences may be found between the alkaline phosphatase extracted from different human placentae. Boyer<sup>4</sup> described three types of electrophoretic pattern and suggested on the basis of their population frequencies that the differences were genetically determined. In this article we show how human placentae may be classified into at least six distinct phenotypes according to the electrophoretic properties of the alkaline phosphatase present. We also give the results of twin studies which indicate that these phenotypic differences depend on the genotype of the foetus, and that at least three relatively common autosomal allelic genes determine this enzyme polymorphism.

Placental extracts were prepared by a modification of Morton's butanol method<sup>5</sup> as used by Boyer<sup>4</sup>. They were subjected to horizontal unidimensional starch-gel electrophoresis at both pH 8.6 and pH 6.0 because it was found that the two sorts of separation were required to give a satisfactory discrimination between the phenotypes. For the separation at pH 8.6 Poulik's *tris*-borate discontinuous buffer system<sup>6</sup> was used, and electrophoresis was carried out at 6 V/cm for 6 h at room temperature. For the pH 6.0 separation the gel was made using a succinic acid/*tris* buffer (0.0025 M in succinic acid, 0.0046 M in *tris*) and the bridge solution consisted of a citric acid/sodium hydroxide buffer (0.41 M in citric acid), and electrophoresis was carried out at 8 V/cm for 6 h in a cold room at +5° C. After electrophoresis the zones of enzyme activity were developed using  $\beta$ -naphthyl phosphate as substrate in a reaction mixture as described by Boyer<sup>4</sup>.

The great majority of placentae can be classified into one or another of six distinct phenotypes according to the pattern of electrophoretic components revealed by these procedures. Fig. 1 illustrates diagrammatically the characteristic electrophoretic patterns seen at pH 8.6 and at pH 6.0. The six phenotypes will be referred to as F, FI, I, SI, FS and S. In phenotypes F, I and S most

of the alkaline phosphatase activity is present in the form of a rapidly moving component. In phenotype F this component is distinctly faster than that in phenotype S both at pH 8.6 and at pH 6.0. In phenotype I the characteristic component has a mobility close to that of the F component at pH 8.6, but at pH 6.0 it is much slower, and has the same mobility as the S component. The phenotypes FS, SI and FI are all characterized by the presence of three rapidly moving components at either one or both pH's used. In each case two of these show mobilities similar to the main components of F, I or S while the third has an intermediate mobility and is also somewhat more intense than the other two. It should be

Fig. 1. Placental alkaline phosphatase phenotypes as revealed by starch-gel electrophoresis at pH 8.6 and pH 6.0.

noted that under the conditions described, phenotypes F, FI and I cannot be unequivocally differentiated from one another at pH 8.6, while at pH 6.0 phenotypes S, SI and I are indistinguishable. Thus separation at both pH's is required for complete discrimination of the six phenotypes. It seems likely that Boyer's<sup>1</sup> type A included our types F, FI and I, and that his type AB included our types FS and SI.

In each of the six phenotypes at least one other component which migrates only very slowly and does not move far from the origin at either pH 8.6 or pH 6.0 is also regularly seen. These slow-moving components exhibit slight differences in mobility in the different phenotypes and these have been found to correlate with the more striking differences observed in the major and more rapidly moving components.

The patterns shown in Fig. 1 include only the principal components seen in the various phenotypes. Several minor components may also be demonstrated in each of the phenotypes provided a sufficiently active preparation is used. Types S, F and I, for example, can be shown to have, besides the major rapidly moving component, two slightly faster and one slightly slower minor components. These minor components appear to parallel the mobility differences shown by the major components they are associated with, and do not interfere with the discrimination of the six phenotypes.

For routine typing, extracts were prepared from only a small portion (1-4 g) of any particular placenta. However, a number of experiments have been carried out in which samples taken from different parts of the same placenta were examined separately. In each case the electrophoretic patterns obtained from different samples of the same placenta were found to be identical.

Table 1 shows the incidence of the various phenotypes in a series of 338 placentae obtained from births at University College Hospital, London. They were derived from single pregnancies of women of European origin, but were otherwise unselected. It will be seen that the relative frequencies of the various phenotypes do not appear to be significantly related to the sex of the offspring. In this series there were 6 examples in which the electrophoretic patterns were different from the six standard phenotypes. They included three further phenotypes each being rare, having frequencies of less than 0.01. These rare types will be considered in detail elsewhere.

Table 1. FREQUENCY OF ALKALINE PHOSPHATASE PHENOTYPES IN 338 SINGLE PLACENTAE FROM A HOSPITAL POPULATION

Phenotype	Sex of Infant		Total
	Male	Female	
S	61	80	141
SF	48	63	111
SI	18	14	32
I	4	1	5
FI	7	8	15
F	14	14	28
Others	1	5	6
	153	185	338

In a smaller series of 64 placentae derived from Negro mothers living in England, 54 were of phenotype S, 5 of phenotype SF, 4 of phenotype SI and 1 of phenotype FI. There was thus a marked excess of phenotype S over that found in the European population, a result which is in agreement with the findings of Boyer<sup>1</sup> and which indicates that quite marked population differences exist.

On the basis of the electrophoretic patterns and the relative incidence of the different phenotypes it is possible to construct a simple genetical hypothesis. This is that the six common phenotypes are determined by three autosomal allelic genes ( $P^H$ ,  $P^I$  and  $P^S$ ), phenotypes F, I and S representing the homozygous genotypes ( $P^H P^H$ ,  $P^I P^I$ , and  $P^S P^S$ ), and phenotypes SF, SI and FI the corresponding heterozygotes ( $P^H P^S$ ,  $P^H P^I$  and  $P^I P^S$ ). The characteristic electrophoretic pattern of each of these postulated heterozygous types consists of three components and the mobilities of two of them are identical to those of the main components in the respective homo-

zygous types. The third enzyme component has an intermediate mobility and it seems possible that it may represent in each case a 'hybrid' enzyme containing polypeptides characteristic of the two other components present. The rare phenotypes also show 'triplet' electrophoretic patterns, and they can probably be regarded as heterozygotes for a rare allele and one or other of the commoner alleles  $P^H$ ,  $P^I$  or  $P^S$ . Several different rare alleles probably occur.

From the observed incidence of the six common phenotypes in the population (Table 1) one can obtain estimates of the gene frequencies of the three common alleles  $P^H$ ,  $P^I$  and  $P^S$ . They are 0.27, 0.09 and 0.64. Using these values one finds good agreement between the observed numbers of the different phenotypes and the expected numbers assuming a Hardy-Weinberg equilibrium (Table 2). In this calculation the small number of rare phenotypes have been excluded.

Table 2. OBSERVED AND EXPECTED NUMBERS OF THE SIX COMMON PLACENTAL ALKALINE PHOSPHATASE PHENOTYPES ASSUMING A HARDY-WEINBERG EQUILIBRIUM WITH GENE FREQUENCIES  $r=0.64$ ,  $q=0.09$  AND  $p=0.27$

Phenotype	Postulated genotype	Expected incidence	Population sample		
			Expected numbers	Observed numbers	
S	$P^H P^H$	$r^2$	0.410	135.9	141
SF	$P^H P^I$	$2pr$	0.246	114.7	111
SI	$P^H P^S$	$2qr$	0.115	33.2	32
I	$P^I P^I$	$q^2$	0.008	2.7	5
FI	$P^I P^S$	$2pq$	0.049	15.1	15
F	$P^S P^S$	$p^2$	0.073	24.2	23
		$(p+q+r)^2$	1.001	331.8	332

It is impractical to carry out an extensive family investigation of the ordinary kind in order to study the genetics of a characteristic which is peculiar to the human placenta. However, it has proved possible to test the genetical hypothesis by studying the distribution of the various phenotypes in a series of pairs of placentae derived from dizygotic twins. Such twin pairs can be regarded simply as pairs of sibs. We have been fortunate in obtaining appropriate material from an extensive investigation of twin births which is being carried out in the Birmingham area under the general direction of Dr. John Edwards with support from the Association for the Aid of Crippled Children.

Table 3 summarizes the results obtained in 380 placentae from 190 dizygotic twin pairs. In each case the placentae were dichorionic and twins of the same sex were included when they could be shown to differ in at least one genetically determined characteristic among 6 red cell antigenic systems and 3 polymorphic red cell enzyme systems. All the twin pairs were from parents of European origin. In 112 placental pairs the alkaline phosphatase phenotypes

were the same, and in 78 pairs they were different. Rare phenotypes were observed in four additional twin pairs, two being alike and two unlike. These four pairs have not been included in the analysis shown in Table 3.

Since many of the pairs are unlike one can exclude the possibility that the placental alkaline phosphatase phenotype is determined by the maternal genotype, because if this were so none of the pairs should have shown differences. It is possible to calculate the expected incidence of like and unlike placental pairs assuming that the alkaline phosphatase phenotypes are not genetically determined but occur essentially at random. In the 190 pairs one would have expected on this basis to find 63.3 pairs which were alike, and 126.7 pairs which were unlike. There is clearly a great excess of like pairs in the dizygotic twin series, and this, of course, is what would be expected if the placental phenotypes depend on the genotype of the foetus.

With six different phenotypes 21 sorts of twin pair may occur. If the phenotypes depend on the foetal genotype then one may test the genetical hypothesis by calculating the expected incidence of each of the different sorts of sib pair, using the gene frequencies derived from the general population sample (the gene frequencies in the Birmingham twin series were found to be essentially the same as in the University College Hospital single pregnancies

series). The calculation is shown in Table 3 and it will be seen that there is in general very good agreement between the numbers of the different sorts of twin pair observed and the numbers expected according to the hypothesis.

We conclude, therefore, that the placental alkaline phosphatase phenotypes are determined by the foetal genotype and that the polymorphism can be largely accounted for in terms of three relatively common autosomal allelic genes. There appear to be quite wide variations in gene frequency in different human populations, and it is probable that a number of rare alleles also occur which may give rise to unusual enzyme patterns. The biological significance of this polymorphism is still quite obscure, but it may well prove of importance in problems concerned with maternal-foetal interaction.

We thank Dr. J. H. Edwards, Institute of Child Health, University of Birmingham, and his colleagues for assistance in the twin investigation, and Dr. M. Crawford of the Galton Laboratory and Prof. W. C. W. Nixon of the Obstetric Department, University College Hospital, London, for further assistance.

## CESTICIDAL ACTIVITY OF SUBSTITUTED DIHYDROBENZO-1,3-OXAZINES

By A. B. SEN, J. C. KATIYAR\* and B. K. BHATTACHARYA

Central Drug Research Institute, Lucknow, India

REMARKABLY little has been done to find an ideal cesticide, and the extract of male fern (*Dryopteris filix-mas*), which has been in use from medieval times, is still the drug of choice. Yet this and other drugs like quinaacrine, dichlorophen, hexylresorcinol, arecoline, etc., are rather toxic and their efficacies are not always predictable. During routine screening of compounds for cesticidal activity, two compounds (TQ-OA 119 and TQ-OA 121) were found active in 10<sup>-7</sup> against *Hymenolepis nana* *in vitro*. This article reports the activity of these compounds against *H. nana* *in vivo* and discusses their comparative therapeutic efficacy.

Compounds TQ-OA 119 (3-(3',4'-dichlorophenyl)-2,4-dioxo-6-chloro-dihydrobenzo-1,3-oxazine) (I) and TQ-OA 121 (3-(2'-chloro-4'-nitrophenyl)-2,4-dioxo-6-chloro-dihydrobenzo-1,3-oxazine) (II) were obtained from Firma Dr. Karl Thomae, Biberach/Riss, West Germany. The compounds were insoluble in water, alkali or acid.

Previously in this laboratory the infection of *H. nana* was maintained in mice. But recently we have found that newly weaned rats of the University of Freiburg strain, which we received through the courtesy of Prof. H. Druckrey, are even more susceptible. There is almost 100 per cent 'take'.

Initially, the *in vitro* screening was done following the method of Sen and Hawking<sup>1</sup>, which allows use of alcohol not exceeding 1 per cent of the medium as a solvent for the compounds.

The compounds were then tested *in vivo* in rats, using the technique of Steward<sup>2</sup>. Each rat under experiment was fed with 200 mature eggs of *H. nana*, later starved on the fourteenth day, given the drug orally in 'Tween 80' suspension on the fifteenth, starved on the sixteenth and killed on the seventeenth day. The remaining worms were collected from the intestine and a score was made depending on their size. The results were compared with those from a control group.

\* Senior Research Fellow, C.S.I.R.

To determine the initial dose for *in vivo* testing the maximum tolerated dose for each compound was first determined. The maximum tolerated dose for TQ-OA 119 and TQ-OA 121 was found to be more than 3 and 3.6 g/kg, respectively. As these were high, a dose about one-sixth the maximum tolerated dose was initially used in rats. The dose was then gradually decreased to find the minimum effective dose which had been taken as the dose which would reduce the average score in the treated animals to one-tenth or less of the average score of the untreated controls.

While comparing the therapeutic efficacy of these compounds with well-known cesticides, it was found that all previous investigations had been carried out in mice. Consequently, for comparison the tests were repeated in

Table 1. SUMMARY OF THE *in vivo* TESTS

	25	2/5	12.7	Slight action
	Control	0/5	80.0	

mice. A summary of the results of *in vivo* tests in rats and mice is presented in Table 1.  
TQ-OA 119 in 500 mg/kg dose cleared all the rats. Though 200 mg/kg dose did not clear all the rats, it removed a substantial amount of worm load, as evident

from the score. 100 mg/kg had less but still considerable action.  
With TQ-OA 121, 750, 500 and 200 mg/kg cleared all the rats. With lower dose of 100 mg/kg only three of the ten rats were cleared, but there was a substantial reduction in the worm load.  
When quinacrine, a well-known oestocidal compound, was tried in 500 mg/kg in rats, four of the ten treated rats died. Only two of the remaining six were cleared, and the treated:untreated ratio of average score was 8.1:183. With lower dose of 200 mg/kg no significant effect was observed.  
In mice, 50 mg/kg of TQ-OA 119 was very effective. Even 25 mg/kg was appreciably effective. With TQ-OA 121, 100 mg/kg removed all the worms from all the treated mice, but 50 mg/kg could not, although the average score was much less than the untreated.  
If maximum tolerated doses for TQ-OA 119 and 121 are taken as 3.0 and 3.6 g/kg, respectively, and minimum effective dose as 50 mg/kg, the therapeutic indexes for these two drugs in mice come to 60 and 72, respectively. The low toxicity of these compounds is proved by the fact that even after administration of maximum tolerated dose in mice the animals did not show any untoward effect during the next seven days and there was no macroscopic changes in the viscera during post-mortem examination. In comparison, the therapeutic index for quinacrine comes to about 8, taking 100 mg/kg as minimum effective dose (Standen, quoting Keeling<sup>3</sup>) and 800 mg/kg arbitrarily as the maximum tolerated dose, which is the LD<sub>50</sub> determined by Bovet *et al.*<sup>4</sup>. Bhat-tacharya and Sen<sup>5</sup> found the therapeutic index to be 5 in the case of BIQ 22. Similarly, safety levels are also low with other known oestocidal drugs.  
The effectiveness of TQ-OA 119 and TQ-OA 121 against *H. nana* in two species of animals (rats and mice) and high therapeutic indexes make them promising as oestocidal drugs. However, TQ-OA 119 in 500 mg/kg and TQ-OA 121 in 150 mg/kg doses when fed orally were ineffective against *Nippostrongylus brasiliensis* infection in rats.

A 'FOUR-EYED' FISH FROM THE DEEP-SEA: *Bathylchnops exilis*  
COHEN, 1958

By PROF. WILLIAM G. PEARCY  
Department of Oceanography, Oregon State University, Corvallis, Oregon

SAMUEL L. MEYER  
Department of Ophthalmology, University of Oregon Medical School, Portland, Oregon

AND  
OLE MUNK  
Institute of Comparative Anatomy, Copenhagen, Denmark

*BATHYLYCHNOPUS EXILIS* Cohen, 1958, a rare North Pacific mesopelagic fish in the family Opisthoproctidae, has an unusual eye. A spherical protuberance, complete with a well-developed lens, is located on the rostro-ventral portion of the orbit (Figs. 1 and 2). This genus is named *Bathylchnops* (meaning 'deep-lamp-eye') because this structure was originally thought to be a photophore or light-producing organ<sup>1,2</sup>. However, its

size and location prompted us to study the eye of *B. exilis* histologically.  
A specimen, 470 mm in length, was captured in an oblique midwater trawl tow from the surface to 1,000 m depth off Oregon. It was alive and displayed vigorous swimming movements when first captured. This large specimen, which was fixed in 10 per cent formalin, provided the main material for examination. One eye was removed

and embedded in celloidin, and serial sections were cut  $15\mu$  thick. Every tenth section was stained with haematoxylin and eosin and mounted. Representative sections were also stained with silver stains, Mallory's trichrome, and Shorr's connective tissue stain. Two small individuals were also examined. The head of a 107-mm specimen and both eyes of a 110-mm specimen were embedded in paraffin, cut into  $8\mu$  serial sections, and stained with haematoxylin and eosin, Heidenhain's azocarmine-aniline blue stain, alcian blue, alcian blue-periodic acid Schiff, periodic acid Schiff, and luxol fast blue.

The eyes of *B. exilis* are large and directed dorsally (Fig. 1a). The anatomical axis of each eye forms an angle of about  $35^\circ$  with the perpendicular, providing a large dorsal binocular field of vision. The secondary globe

Fig. 1. Head of *Bathylchnops exilis* (470 mm specimen). (a) Dorsal view, (b) lateral view showing secondary globe ( $G_2$ ).

Fig. 2. Left eye (470 mm specimen). CP, Corneal projections,  $G_2$ , secondary globe,  $L_1$ , pupal and lens;  $L_2$ , scleral lens of secondary globe.

Fig. 3. Section through entire eye (470 mm specimen). C, Cornea; CA, choroid gland; CP, corneal projection; I, iris;  $L_1$ , main lens;  $L_2$ , scleral lens of secondary globe;  $R_1$ , retina of main globe;  $R_2$ , retina of secondary globe; S, scleral cartilage.

is located on the rostro-ventral portion of the main globe, close to the limbus of the cornea. It is directed in a ventral and slightly caudal direction (Figs. 1b and 2). Dimensions of these structures are given in Table 1.

Table 1. DIMENSIONS OF SOME OPTIC STRUCTURES OF A *B. exilis* 470 MM IN LENGTH

	Size (mm)
Main globe	
Anterior-posterior diameter	14.5
Equatorial diameter	18.0
Corneal diameter	18.0
Elevation of cornea above limbus	3.0
Secondary globe	
Anterior-posterior diameter	7.6
Equatorial diameter	8.7
Scleral lens diameter	3.0
Elevation of lens above limbus	2.0
Corneal projections	
Dorsal projection	$5.0 \times 3.0$
Elevation above limbus	2.0
Ventral projection	$3.5 \times 3.0$
Elevation above limbus	2.0

Two peculiar thickenings, appearing as whitish regions in Figs. 2 and 1, were noted near the limbus of the cornea behind and dorsal to the secondary globe. These structures were elevated several millimetres above the limbus (Table 1). They were not found in our small specimens, but were noted by Cohen<sup>8</sup> in *Bathylchnops* more than 112 mm.

A section through the secondary and main globes is seen in Fig. 3. The secondary globe, located on the rostro-ventral part of the main globe, is enclosed by hyaline scleral cartilage. In the ventral part of the secondary globe there is a spherical lens-like structure, consisting of concentrically lamellated connective tissue. This lens is biconvex in sections of the small specimens. The secondary lens is continuous with and differentiated from the adjoining sclera. The possibility of phospholipids in the periphery of the lens, indicated by staining with luxol fast blue, suggests that the refractive index may exceed the usual values for teleostean cornea, which differ only slightly from that of sea-water.

Within the secondary globe is a retinal diverticulum, which is continuous with the retina of the ventral part of the main globe. No secondary optic nerve is present. Where the retina of the diverticulum overlies the inside

Fig. 4. Retina of (a) secondary globe and (b) main globe. R, Layers of outer rod segments or acromeres; ON, outer nuclear layer; OP, outer plexiform layer; IN, inner nuclear layer; IP, inner plexiform layer; G, ganglion cell layer; NF, optic nerve fibre layer.

surface of the lens of the secondary globe, it is reduced to two layers of endothelium-like cells, continuous with the retina proper and the pigment epithelium respectively. There is no pigment in the layer which is continuous with the pigment epithelium, and the choriocapillaris and choroidal pigment are also absent in this region. Light can thus pass directly from the secondary lens through the unpigmented window in the retinal diverticulum to the normally differentiated secondary retina. A narrow slit-like opening connecting the lumen of the diverticulum with the interior of the main globe was noted by gross dissection. The slit, about 2 mm in length, was covered by an operculum which prevented light from entering the main globe. It opened into the rostro-dorsal portion of the secondary globe. The exposed opening could be clearly discerned when a beam of light was projected on to the secondary lens.

The retina of the secondary globe is very similar to that of the main part of the eye (Figs. 4a and 4b). As with other deep-sea fishes, only rods are present in the photoreceptive layer of the retina<sup>1</sup>. In *B. exilis* the rod layer consists of several layers of outer segments or acromeres. Four layers are found in the thickest portion of the retina in the central part of the fundus (Fig. 4b). The rods are narrow and many occupy the area above a single bipolar cell. The dense outer nuclear layer and the progressive decrease in the number of cells in the inner nuclear and ganglion cell layers indicate a high degree of retinal summation and therefore acute sensitivity.

The two projections on the cornea, located above and behind the secondary globe (Fig. 2), are nearly circular in cross-section (Fig. 3). These structures, which are differentiated from and continuous with the cornea, appear

very similar histologically to the lens of the secondary globe. Muscles, probably derived from tensor chorioideae, insert on the base of the secondary globe, on the corneal thickenings above the secondary globe, and on the sclera. They may be able to move these structures, perhaps to assist in photoreception over a wider field. In other respects the main globe of *B. exilis* shows few deviations from the typical teleostean pattern.

The highly specialized and well-developed eyes of *B. exilis* indicate that photoreception plays an important part in its orientation and ecology. The large eyes are directed dorsally and are separated by only a thin septum. Because of this there is a wide dorsal binocular field of vision. Unlike many other deep-sea fishes, however, *B. exilis* has achieved an enlarged binocular field of vision without resort to the specialized tubular ('telescopic') shape of the eyeball. Binocularity in deep-sea fishes may be useful for space perception in an environment where the usual monocular cues for estimating distance are lacking<sup>2,4</sup>. The well-developed axial musculature and vigorous movement of *B. exilis* while alive indicate that it is a strong swimmer. For such a fast-swimming predator, snapping at small, dimly silhouetted or bioluminescent prey in the dark environment, stereoscopic depth perception would presumably be a distinct advantage. Sensitivity may also be increased by binocular vision which lowers the threshold below that of monocular vision<sup>2,4</sup>. Likewise, the several rows of acromeres in the retina may represent a means of increasing sensitivity without substantially decreasing resolving power<sup>4</sup>.

The specialization of the eyes of *B. exilis* for dorsal binocular vision restricts their visual fields, but the secondary globes compensate for this by providing for light and movement perception in a ventral direction. This is important for detection of prey or predators, or their bioluminescence, in water below. The two peculiar corneal thickenings (see Fig. 2), originally called photogenic tissue, may also serve as lenses and further increase the periscope field of vision. The thickenings are elevated above the orbit so that they can be seen above the lens when viewing the intact eye from behind. Consequently, light caudal to the fish striking these lens-like structures may be refracted on to the lens and hence on to the main retina.

Evolution of the secondary globes appears to be closely related to the development of stereoscopic vision. This is supported by the fact that similar, but structurally far simpler, specializations are present in the tubular eyes of some deep-sea fishes. Analogous structures have been described by Brauer<sup>3</sup> in the related genera *Dolichopteryx*, *Opisthoproctus* and *Winiwaria*. In these fishes a well-developed portion of the accessory retina forms a small diverticulum, in which part of the retinal pigment epithelium and the adjacent choroid are unpigmented, forming a window through which light may be perceived. Unlike *B. exilis*, however, light does not strike a normally differentiated retina but first strikes the rods adjacent to the window. Moreover, none of these other fishes has a secondary lens for focusing light. *B. exilis*, which lacks the wide visual field provided by tubular eyes, has the most highly evolved secondary 'eye'. It also has corneal protrusions. Both structures increase the field of vision while maintaining the advantages of the typical shape of the main globe.

The large *B. exilis* was captured while making oceanic collections under AEC contract AT(45-1)1726. The work was supported in part by a grant from the National Science Foundation (GB 1588) to one of us (W. G. P.).

# IMMUNOLOGICAL ELECTRO-ADSORPTION METHOD AS APPLIED IN THE CASE OF MICE LEUKAEMIA

By C. MATHOT, Dr. A. ROTHEN and S. SCHER

The Rockefeller Institute, New York

THE immunological electro-adsorption method recently described<sup>1</sup> proved most sensitive in detecting antibodies in cases where only haemagglutinin or complement-fixation tests were available. Both sensitivity and rapidity of the experimental procedure make the method particularly useful. It consists in adsorbing for 1 min or less, on a metalized glass slide, a thin layer of material containing some antigen. The antigen is adsorbed from a solution of a partially purified fraction under the influence of an electric current with the proper polarity, the slide for all cases tested thus far being negatively charged. Then the slide is immersed in a dilute solution of the antiserum to be tested, also in the presence of a weak current, the slide being positively charged this time. It is found that the layer adsorbed after the antiserum treatment is thicker when the serum is homologous rather than heterologous or normal. The thickness of the layers, which runs from a few Å to a few hundred Å, is measured optically with an ellipsometer. As described in ref. 1, it was possible to detect immunological reactions for eight arthropod-borne viruses, and the corresponding antisera could be diluted 1 to 10<sup>4</sup> before specific reaction failed to be observed.

It was of interest to extend this method to other systems, and the results obtained with a virus from leukaemic mice (Friend's virus)<sup>2</sup> are presented in this article. (We thank Dr. Alice Moore for suggesting Friend's virus for a possible testing of the electro-adsorption method and Dr. Charlotte Friend for providing us with an infective extract of spleen.)

The infection of the mice was carried out according to the method described by Friend<sup>2</sup> by injecting a homogenate of spleen of diseased animals intraperitoneally into *N.O.S.* Swiss mice. The antigenic material used for the immunological test was prepared by two methods.

In the first method, described by Friend<sup>2</sup>, an antigenic fraction was obtained from diseased spleens homogenized in saline (the weight of the diseased spleens varied from 1 to 5 g). A clear homogenate containing 20 per cent by weight of the original spleen was obtained after centrifugation at 10,000*g*. This preparation was called antigen stock solution.

In the second and better method, described by de Harven and Friend<sup>3</sup>, the virus was recovered from the plasma of infected mice bled from the axilla. The plasma was submitted to fractional centrifugation and filtered through three 'Millipore' filters of pore sizes 0.65μ, 0.3μ and 0.22μ.

Immunological electro-adsorption tests were performed essentially as described in ref. 1. The adsorptions were carried out on glass slides, 6 mm × 120 mm, coated by evaporation with 'Inconel' (80 per cent nickel and 20 per cent chromium). 1.5 ml. of the antigen solution and 0.8 ml. of the serum diluted 1 to 15 in veronal buffer,

pH 7.5, were used for each test. The slides were negatively charged for the adsorption of the antigen and positively charged for the adsorption of the sera. The duration of the adsorption was 30 sec in every case. The current was maintained at 0.300 m.amp for the adsorption of both antigen and antibodies using a constant current electronic power supply (available from Scitronics, 419 East 73rd Street, New York).

A summary of the results obtained with 17 mice is presented in Table 1. The antigen used for these tests was the stock solution from the spleens diluted 1 to 5 in water. The sera of the infected mice were obtained through orbital bleeding and tested daily until the animals were killed. The number of days elapsed between infection and the time of bleeding is indicated in column 1. Each successive column corresponds to the results obtained with a single mouse. The first group of 5 mice was infected with the stock solution, the second group of 6 mice was infected with the stock solution diluted 1 to 2, and the last group with the stock solution diluted 1 to 4 in saline. The numbers indicate the thickness in Å of the layers adsorbed during the serum treatment. It is apparent that only two days after infection with either the stock solution or the solution diluted 1 to 2, the layers adsorbed from the antisera are significantly thicker than the layers adsorbed from the serum of the same animals prior to infection. This is interpreted as indicating a very rapid antibody formation. Fourteen days after infection the thickness of the layers adsorbed from the sera ranged from 103 Å to 126 Å as compared with 52 Å to 59 Å for normal sera. As an additional control, 6 mice were injected with a 20 per cent homogenate in saline of normal spleen. The thickness of the layers obtained after adsorption of the sera 7 days after injection ranged between 56 Å and 59 Å, the values found for the sera of non-injected mice.

The thickness of the layers obtained after the antigen adsorption was 70–80 Å when the undiluted stock solution was used and 25–35 Å when the solution was diluted 1 to 4 in saline, as was the case for the experiments presented in Table 1.

Similar experiments were carried out with antigen preparations obtained from the blood of infected mice, as already described here. After filtration and centrifugation of the plasma for 30 sec at 30,000*g*, most of the antigenic material remained in the supernatant. The pellet obtained after further centrifugation at 38,000*g* for 1 h was resuspended in saline. It contained some antigenic material which could be adsorbed on the slide since the thickness of the layer adsorbed was 79 Å after treatment with an antiserum and 52 Å after treatment with a normal serum.

In another run, after low-speed centrifugation (15,000*g*) for 90 min and filtration, the plasma was centrifuged at 44,000*g* for 90 min. The supernatant contained some

Table 1

Days	Stock solution					Stock solution diluted 1/2 in saline					Stock solution diluted 1/4 in saline

7	..	..	88	..	115	..	84	73	..	91	63	98	63	..	..	..
8	112	..	..	..	..	..	91	72	..	..	..	68	..	..	..	66
14	121	..	..	118	..	..	..	..	120	..	..	..	..	111	106	120
16	..	..	..	..	..	..	119	..	..	99	..	..	..	..	..	..
18	80	99	..	..	101	93	..	97	..	85	98	106	..	99	..	..

antigenic material, since slides after adsorption of this material could adsorb layers 43 Å, 55 Å, 57 Å, 62 Å and 69 Å thick from sera obtained 0, 4, 7, 18 and 48 days, respectively, after infection. This supernatant was further centrifuged for 3 h at 46,000*g*. The supernatant was inactive this time, but the pellet was found to be antigenic. It took, however, two days for the material to become active after the pellet was resuspended. All centrifugations were carried out at 4°–6° C.

A few experiments were made to test the stability of the antigen as a function of temperature. After serum treatment, the slide adsorbed 50 Å with a normal serum and 46 Å with the antiserum when the antigenic preparation had been heated 15 min at 90° C. Heating the antigen at 50°–55° C for 15 min did not diminish the antigenic properties (93 Å after treatment with the immune serum and 40 Å with the normal serum). After heating the antigen at 65°–70° for 15 min, an increase of 70 Å was observed after immune serum treatment as compared with 40 Å after normal serum treatment. These results indicate that the antigenic activity is more stable than the infectivity of the agent which, according to Friend<sup>4</sup>, is destroyed by heating at 56° C for 30 min.

Some experiments were carried out using extracts of either diseased or normal spleens as sources of antigen to be adsorbed on the slides. Three different types of serum

Fig. 1

Fig. 2

were adsorbed afterwards on the slides. The results have been summarized in Fig. 1, where the thickness of the layer adsorbed following serum treatment is plotted against duration of adsorption. The antigen stock solution from diseased spleens was used for the experiments summarized by curves 1, 2 and 3, and normal spleen extracts for the experiments summarized by curves 4, 5 and 6. Dashed curve 1 was obtained when the stock solution was diluted 1 to 4 in saline. Homologous serum was used for curves 1 and 4, normal serum for curves 2 and 5, and serum from a mouse injected with normal spleen 7 days before bleeding for curves 3 and 6. It is apparent that a slide coated with an extract of normal spleen (curves 4, 5 and 6) is unable to differentiate homologous from normal serum in contrast to a slide coated with an extract of diseased spleen (curves 1, 2 and 3).

The thickness of the layer adsorbed following antiserum treatment is a qualitative measure of the level of antibodies in the serum. The thickness observed, for a given antigenic preparation, tends to a maximum as the concentration in antibodies increases. A better way of estimating the antibodies titre of a serum by this method is to dilute the serum until the thickness of the adsorbed layer is equal to that observed for a normal serum at the same dilution. This has been done in Fig. 2, where the dilution of a given serum, at which a specific adsorption disappears, is plotted against the time elapsed between the infection of the animal and the moment at which the serum is tested.

In no case could the serum be diluted more than 1 to 50. This is in sharp contrast to the results reported for eight arthropod-borne viruses<sup>1</sup> when sera could be diluted 1 to a million before a specific adsorption disappeared. Nevertheless, it is interesting to note that this new immunological electro-adsorption method seems applicable to a variety of antigens.

This work was supported by grant GM-08815 from the U.S. Public Health Service.

## IMMUNOLOGICAL AND BIOCHEMICAL INVESTIGATIONS OF HUMAN SERUM HAPTOGLOBIN: COMPOSITION OF HAPTOGLOBIN-HAEMOGLOBIN INTERMEDIATE, HAEMOGLOBIN-BINDING SITES AND PRESENCE OF ADDITIONAL ALLELES FOR $\beta$ -CHAIN

By PROF. BONG-SOP SHIM, TONG-HO LEE and YOON-SE KANG

Department of Biochemistry, Catholic Medical College, Myong-Dong, Seoul, Korea

**H**APTOGLOBIN is an  $\alpha_2$ -protein present in the serum of many species which has the specific capacity to bind with haemoglobin stoichiometrically *in vivo* and *in vitro*<sup>1-3</sup>. In 1955, Smithies<sup>4</sup> reported the existence of genetically determined variations in haptoglobin using starch-gel electrophoresis. The three common haptoglobin phenotypes, Hp 1-1, Hp 2-1 and Hp 2-2, can be

now sub-classified into six sub-phenotypes, Hp 1F-1F, Hp 1F-1S, Hp 1S-1S, Hp 2-1F, Hp 2-1S and Hp 2-2, by urea-mercaptoethanol-formate buffer starch-gel electrophoresis after reductive cleavage of the disulphide bonds of the partially purified haptoglobin samples<sup>5,7</sup>. The allele designations are referred to the fast-migrating so-called  $\alpha$ -chains. Additional haptoglobin phenotypes were

recognized in a Brazilian population<sup>8</sup>, and the distribution of the genetic haptoglobin sub-types in various populations have been reported<sup>9,10</sup>. So far, five normal haptoglobin alleles have been found ( $Hp^{1S}$ ,  $Hp^{1F}$ ,  $Hp^{2F}$ ,  $Hp^{2S}$  and  $Hp^{3S}$ ) (refs. 8 and 10). In addition to the usual genetic types, the presence of some electrophoretically abnormal types, for example, Johnson type<sup>11</sup>, and immunologically atypical haptoglobins were also recognized<sup>12-14</sup>.

The molecular structure underlying the polymorphism of each genetic type of haptoglobins has been examined by several investigators using a variety of physicochemical and immunological techniques. Most recently, Shim and Bearn<sup>14</sup> had demonstrated that the antigenic determinants of the haptoglobin molecule reside in both  $\alpha$ - and  $\beta$ -chains, using rabbit antiserum to purified type 1F-1S human serum haptoglobin, and proposed a tentative model for the secondary structure of human type 1-1 haptoglobin.

The work recorded here was performed to elucidate further the antigenic structure of type 2-2 haptoglobin, the composition of the so-called haptoglobin-haemoglobin intermediates, the haemoglobin-binding sites of haptoglobin, and the possible polypeptide compositions of type 2-2 haptoglobin molecules.

The isolation of each genetic type of haptoglobin was performed according to the method as previously described<sup>14</sup>. The purity of the prepared samples was confirmed by starch-gel electrophoresis and immunoelectrophoresis against horse anti-human serum antiserum (Pasteur Institute, lot AH-223-4). Isolation of  $\alpha$ - and  $\beta$ -polypeptide chains of type 2-2 haptoglobin was per-

Fig. 1. Urea-mercaptoethanol-formate buffer (pH 3.1) starch-gel electrophoresis of the isolated  $\alpha$ - and  $\beta$ -polypeptide chains of type 2-2 haptoglobin by gel filtration with 'Sephadex G-75' column. Gel-filtration was carried out at room temperature with 6 M urea-1 M acetic acid, and the other conditions were the same as previously described (ref. 14). Urea-gel electrophoresis was carried out at 15 V/cm for 6 h in the cold (+4°C). Migration upwards. From left, isolated  $\beta$ -chain, reduced 2-2 type haptoglobin, and isolated  $\alpha$ -chain.

Fig. 2. Starch-gel electrophoresis (borate buffer, pH 8.9) of the gel-filtrated fraction of purified type 2-2 haptoglobin on 'Sephadex G-200' column (3 cm x 70 cm). Gel-filtration was carried out with 0.1 M HCl buffer pH 8.0, containing 1.0 M sodium chloride, at room temperature with a flow rate of 3 ml/h. The protein peak was divided into five fractions. Migration upwards. From left, control whole serum sample, and from part, second, middle, fourth and later part of the protein peak. The pattern clearly demonstrates that slower migrating bands in starch-gel electrophoresis of type 2-2 haptoglobin have larger molecular size than those relatively fast migrating bands.

formed according to the method which was previously applied to type 1-1 haptoglobin using 'Sephadex G-75' column<sup>14</sup>. However, in the case of type 2-2 haptoglobin more prolonged treatment with the reducing agent and incorporation of urea to 6 M into the eluting solution were necessary to obtain clear separation. The isolated polypeptide chain was confirmed by urea-mercaptoethanol-formate buffer starch-gel electrophoresis (Fig. 1).

The relative percentage of the  $\alpha$ -chain in type 2-2 haptoglobin molecules was 33.4 per cent, which indicates the presence of equal numbers of  $\alpha$ - and  $\beta$ -chain in type 2-2 haptoglobin as well as in type 1-1 haptoglobin molecule<sup>14</sup>, if we assume that the molecular weight of  $\alpha$ -chain is about 18,000 (refs. 15 and 16) and that of  $\beta$ -chain is 36,000 (ref. 14) (by indirect calculation). The difference of the molecular size in multiple bands in starch-gel electrophoresis of type 2-2 haptoglobin can easily be shown by gel-filtration with 'Sephadex G-200' column (Fig. 2). Then, if we assume that the multiple bands of type 2-2 haptoglobin indicate the various degree of polymerization of both chains, each band might represent the following composition:  $(\alpha\beta)_1$ ,  $(\alpha\beta)_2$ ,  $(\alpha\beta)_3$ ,  $(\alpha\beta)_4$ , ... in contrast to  $(\alpha\beta)_1$  of type 1-1 haptoglobin. From these considerations, the composition of the multiple bands of 2-1 type might be  $(\alpha\beta)_1$ ,  $(\alpha\beta)_2(\alpha\beta)_1$ ,  $(\alpha\beta)_3(\alpha\beta)_1$ ,  $(\alpha\beta)_4(\alpha\beta)_1$ , ... because artificial mixture of type 1-1 and 2-2 does not represent normal 2-1 type.

Fig. 3. Starch-gel electrophoretic patterns (borate buffer, pH 8.9, 15 V/cm for 4 h in the cold) of the gel-filtrated fractions of purified type 1-1 haptoglobin sample which was saturated with haemoglobin to 40 per cent of its haemoglobin-binding capacity. Gel-filtration was carried out on 'Sephadex G-200' column (2.3 cm x 55 cm) with 0.1 M pH 7.5 phosphate buffer with a flow rate of 2 ml/h. The protein peak was divided into 6 fractions. Migration upwards. From left, first, second, third, fourth, fifth and sixth fraction. Extreme right, control serum sample. Amido black 10B stained. With benzidine, slow-migrating middle and third bands only were stained, which indicates that the first band is free haptoglobin, and the middle and the third bands are haptoglobin-haemoglobin intermediate and haptoglobin-haemoglobin complex, respectively. The separation was not satisfactory; however, one can easily recognize the differences in the relative amounts of the free, the intermediate and the complex in each fraction. This indicates that the faster mobility of the intermediate than the complex in starch-gel electrophoresis at both pH 8.9 and 6.9 is mainly due to its molecular size.

So far, no direct evidence has been presented on the composition of the so-called haptoglobin-haemoglobin intermediates which appear when haptoglobin is under-saturated with haemoglobin, except a few hypotheses<sup>17,18</sup>. From the determination of molecular weight of the haptoglobin-haemoglobin intermediate Jayle and Moretti<sup>18</sup> believed that the intermediate might consist of two molecules of haptoglobin and one molecule of haemoglobin. However, this finding is inconsistent with the facts that the intermediate migrates faster than haptoglobin-haemoglobin complex in both pH 8.9 borate and pH 6.9 phosphate buffer starch-gel electrophoresis, because in pH 6.9 free haemoglobin migrates slower than 1-1 haptoglobin-haemoglobin complex as shown by Laurell<sup>17</sup>. We added haemoglobin to the purified type 1-1 haptoglobin to 40 per cent saturation of its haemoglobin binding capacity and run gel filtration using 'Sephadex G-200' column with 0.1 M, pH 7.5 phosphate buffer. The separation of type 1-1 haptoglobin-haemoglobin complex, 1-1 haptoglobin-haemoglobin intermediate and free 1-1 haptoglobin was not complete, but partial separation could be achieved

as shown in Fig. 3, which demonstrates that the molecular size of the 1-1 intermediate is smaller than the 1-1 haptoglobin-haemoglobin complex, but larger than free 1-1 haptoglobin. The analysis of the amount of haemoglobin in each fraction showed that the intermediate-rich fraction contained less amount of haemoglobin than the haptoglobin-haemoglobin complex-rich fraction. These data suggest that the 1-1 intermediate consists of one molecule of haptoglobin and half-molecule of haemoglobin. Similar intermediates could easily be recognized in 2-1 and 2-2 type haptoglobins when the sample is under-saturated with haemoglobin. Recently, Nagel and Ranney<sup>19</sup> have shown that haptoglobin binds with haemoglobin *F* ( $\alpha_1^A\gamma_1^A$ ), *A*<sub>1</sub> ( $\alpha_1^A\beta_1^A$ ), *I* ( $\alpha_1^A\beta_1^A$ ) and Lepore ( $\alpha_1^A\beta_1^A$ ), but not with haemoglobin *H* ( $\beta_1^A$ ) and Barts. ( $\gamma_1^A$ ). Therefore, the half-molecule of haemoglobin in the intermediate should be symmetrical dimer ( $\alpha_1^A\beta_1^A$ ,  $\alpha_1^A\beta_1^A$ ,  $\alpha_1^A\beta_1^A$  or  $\alpha_1^A\beta_1^A$  Lepore). The experiment to obtain direct evidence of this hypothesis is now being carried out.

To investigate the antigenic structure and haemoglobin binding sites of haptoglobin molecule, we immunized the rabbits with purified type 2-2 haptoglobin and with the isolated  $\alpha$ - and  $\beta$ -chain of 2-2 type haptoglobin with complete Freund's adjuvant according to the method as previously described<sup>14</sup>. Among four rabbits which were immunized with type 2-2 haptoglobin, one rabbit antiserum showed spur between each normal genetic type as demonstrated by Korngold<sup>15</sup>, which indicates that type 2-2 and 2-1 haptoglobin have more antigenic determinants than type 1-1 haptoglobin. The anti-2-2 serum also showed spur between free haptoglobin and haptoglobin-haemoglobin complex of same genetic type as demonstrated by Beuing *et al.*<sup>21</sup>. The most interesting results were obtained with anti- $\beta$ -chain antiserum which reacted only with free haptoglobin, but not with haptoglobin-haemoglobin complex (Fig. 4). In contrast to anti- $\beta$ -chain antiserum, the anti- $\alpha$ -chain antiserum reacted with both free haptoglobin and haptoglobin-haemoglobin complex. These results indicate that haptoglobin binds with haemoglobin at  $\beta$ -chain, and that most antigenic determinants of  $\beta$ -chain are covered by haemoglobin. Each genetic type of haptoglobin showed identical reaction against anti- $\beta$ -chain antiserum. Therefore, the fact that anti-2-2 serum absorbed with type 1-1 still reacted with both free and haemoglobin-bound 2-1 and 2-2 type, but not with free 1-1 type, which was also demonstrated by Korngold<sup>15</sup>, suggests that the antigenic differences among normal genetic types of haptoglobin reside mainly in the  $\alpha$ -chains.

Recently, Robson and others<sup>22</sup> described some rare haptoglobin types, of which Hp 1-P, Hp 2-P and Hp 2-L

Fig. 4. The reactions of  $\beta$ -chain specific antiserum with free haptoglobin and haptoglobin-haemoglobin complex. Centre well: anti- $\beta$ -serum, lower left well: free 2-2 type serum, lower middle well: 1-1 type; lower right well: 2-1 type serum. Upper left well: haemoglobin-saturated 2-2 type serum; upper middle well: haemoglobin-saturated 1-1 type; upper right well: haemoglobin-saturated 2-1 type serum. The anti- $\beta$ -chain serum reacted only with free haptoglobin and haptoglobin-haemoglobin intermediate (not shown in the illustration), but not with haptoglobin-haemoglobin complex, and showed reaction of identity among each genetic type of free haptoglobins.

seemed to have lost partially their haemoglobin-binding capacity, which suggest the variation in haemoglobin-binding sites of the  $\beta$ -chain. We<sup>22</sup> also observed a haptoglobin variant which completely lost its haemoglobin-binding capacity. These observations suggest that there exist two haemoglobin-binding sites per ( $\alpha\beta$ )<sub>2</sub> sub-unit of the haptoglobin molecules each for half-molecule of haemoglobin, and when only one of them is bound with half-molecule of haemoglobin it appears as the haptoglobin-haemoglobin intermediate. Indirect evidence of the existence of two haemoglobin-binding sites in the haptoglobin molecule has already been presented from this laboratory<sup>24</sup>. So, it is plausible to think that Hp 1-P, 2-P and 2-L (ref. 22) are variants in one of the two haemoglobin-binding sites of  $\beta$ -chain (strictly speaking, per  $\beta$ <sub>2</sub> sub-unit), and the latter type<sup>22</sup> might be a variant in both sites. Therefore, electrophoretically normal but immunologically atypical type haptoglobin<sup>13,14</sup> might be a variant at the parts other than the haemoglobin-binding sites. However, this does not necessarily indicate that the haemoglobin-binding sites are themselves involved in the antigenic determinants, because some abnormal type<sup>22</sup> showed normal immunological properties which suggest that haemoglobin just covers the area of the antigenic determinants of  $\beta$ -chain.

The atypical haptoglobin described by Aly *et al.*<sup>13</sup>, and also by Beuing *et al.*<sup>21</sup>, which was reported to have more antigenic determinants than normal haptoglobin could be explained on this basis, provided the atypical haptoglobin (Marburg) partially lost its haemoglobin-binding capacity, because they demonstrated the spur formation among haemoglobin-saturated samples. It seems that haptoglobin Marburg has no really additional antigenic determinants, or rather, possibly, less than normal haptoglobin, but just a variant in the area of haemoglobin-binding site of the  $\beta$ -chain so that the normal antigenic determinants could still react with the antibodies, while those determinants in the normal haptoglobin are covered by haemoglobin. In fact, haptoglobin Marburg was found to be more antigenically deficient than normal haptoglobin when reacted against our rabbit anti-1-1 type haptoglobin antiserum<sup>25</sup>. This is the reason why the spur disappeared when haemoglobin-saturated haptoglobin Marburg was compared with unsaturated normal 2-1 type haptoglobin<sup>21</sup>.

Family examination of this atypical haptoglobin<sup>13</sup>, 1-P and 2-L types of Robson *et al.*<sup>23</sup>, clearly showed that these types are genetically determined. These observations suggest that the molecular structure of haptoglobin is controlled by two independent genes, one for  $\alpha$ -chain and the other for  $\beta$ -chain. Then, the alleles Hp<sup>P</sup> and Hp<sup>L</sup>, which were designated by Robson and others<sup>23</sup>, should be the variant alleles of  $\beta$ -chain. Therefore, we propose to designate the allele for normal  $\beta$ -chain as Hp<sup>SN</sup>, Hp<sup>P</sup> as Hp<sup>SP</sup> and Hp<sup>L</sup> as Hp<sup>SL</sup>, respectively, to distinguish from those alleles for  $\alpha$ -chains. It is very interesting to note that the biosynthesis of haptoglobin is controlled by a mechanism very similar to that of haemoglobin synthesis and that both  $\alpha$ -chain and  $\beta$ -chain variants exist.

## THE HYPOTHALAMO-NEUROHYPOPHYSIAL SYSTEM AND THE MILK-EJECTION REFLEX

THE practice of *Dairy Science Abstracts* of publishing review articles covering a wide range of topics seems to have found favour, since it has become well established. The latest example<sup>1</sup>, under the same title as this article, is published in two parts in successive issues. It is likely to prove tough going for most regular readers since much of it is concerned with various aspects of an area which, following a fairly recent initiative by Unesco, may properly be designated as 'brain research'. However, it is likely to interest many workers in the biological and medical sciences.

It is no novel idea that the discharge of milk from the mammary gland during suckling or milking is an active process involving the unconscious participation of the mother. That the essence of this concept has been intuitively known from ancient times is attested by numerous works of art, some of which illustrate the classical myth which tells of the trick played by Zeus on Hera to immortalize Herakles, incidentally giving rise to the galaxy and also, in some versions, the lilies of the field. The best known representations of this are Tintoretto's canvas 'The Origin of the Milky Way' in the

National Gallery (London), the lower portion of which, depicting the origin of the lilies, is believed to have been excised, and Rubens's later version in the Prado (see ref. 2). The same idea has been empirically exploited to aid in obtaining milk from domestic animals in ancient civilizations and by primitive peoples in to-day's developing countries, as has been recorded in several recent accounts<sup>3,4</sup>, the latest and most detailed of which is that of Amoroso and Jewell<sup>4</sup>.

The concept that milk withdrawal from the mammary gland involves a nervous reflex, in the absence of which only sub-optimal amounts of milk are available, was first propounded more than half a century ago, and its most prominent exponents were Gaines in the United States and Hammond in Britain. However, it is only following the original suggestion of Ely and Peterson nearly twenty-five years ago that increasing knowledge had led to the general acceptance of the view that the reflex is really a neuro-endocrine reflex in which the final stage is the release into the blood from the posterior pituitary of the hypothalamic hormone oxytocin. This octapeptide hormone, now available in synthetic form

because of the classical pioneer work of du Vigneaud, is the agent which causes the contraction of a specific target tissue in the mammary gland, the myoepithelium, so that a large proportion of the milk otherwise held unavailable is squeezed down into the storage cisterns or sinuses from which the suckling or milker can readily remove it. There is now a considerable amount of evidence about various features of the role of the hypothalamo-neurohypophyseal system in the neuroendocrine milk-ejection reflex, and it is this field which is reviewed by Dr. Robert Denamur, who has himself with his colleagues made notable contributions to the subject. His treatment is comprehensive rather than critical, even where, as in consideration of work on blood oxytocin-levels, critical discussion would have been particularly valuable. Despite the fact that in the introduction he disclaims any attempt to compile an exhaustive bibliography, there are no fewer than 885 references.

The article bears signs of a translation from a foreign language, and the reader will sometimes be disconcerted to meet the names of distinguished American workers under an unfamiliar guise, as when van Dyke is shortened to Dyke. This no doubt arises from the over-zealous application of the house rules of an organization the primary purpose of which is, in current idiom, the retrieval of information. There is also, perhaps inevitably, a certain amount of repetition. Nevertheless, Dr. Denamur provides a valuable synthesis of basic scientific knowledge of a subject which is fundamental to a matter of considerable technological importance, namely, how to carry out the milking of domestic animals, especially cows, on a commercial scale with optimum efficiency. As might be expected, this subject has for long been of great interest to Russian animal physiologists and it is interesting to note that their preoccupation has been mainly with segmental nervous reflexes which they believe are elicited by the milking stimulus and, having a shorter latency, precede the neuro-endocrine milk-ejection reflex. The segmental reflex is believed to control the tone of smooth muscle elements in the walls of the cisterns and larger ducts of the bovine udder and, by assisting the flow of milk

and its accommodation in the udder cisterns, to facilitate the action of the neuro-endocrine milk-ejection reflex. Recent reviews of Russian work in this field available in English translation are those of Baryshnikov<sup>4</sup> and Zaks<sup>5</sup>. It should be added that an intriguing element of complexity has been added to the situation by the fact that a few years ago Dr. Denamur himself, as well as some of the Russian workers, obtained results which question the need for the intervention of the central nervous system in the process of milk withdrawal in small ruminants such as sheep and goats; for, in animals with completely deafferented udders, it was possible to obtain normal yields of milk by careful hand-milking. In accordance with this, Folley and Knaggs<sup>6</sup>, in experiments on hand-milked goats, found that more often than not oxytocin could not be detected in the pituitary effluent blood following the milking stimulus even though the milk yields were normal.

It is to be hoped that Dr. Denamur's review will come to the attention of interested research workers whose reading does not normally cover the field of agricultural research. It should be added that reprints of the two parts of the article are available under one cover from the Central Sales Branch, Commonwealth Agricultural Bureaux, Farnham Royal, Bucks, at the modest price of ten shillings for what is in effect a short monograph which will be a useful reference source for some time to come. Credit is due equally to the author for his methodical and logical treatment of what has now become a rather complicated body of information and to the staff of *Dairy Science Abstracts* for the successful completion of an exacting task of editorship. ## NECROSIS OF THE PANCREAS, PAROTID AND LACHRYMAL GLANDS ASSOCIATED WITH ENCEPHALOMYOCARDITIS VIRUS INFECTION

By DR. J. E. CRAIGHEAD

Department of Pathology, Peter Bent Brigham Hospital and Harvard Medical School, Boston, Massachusetts

RECENT studies in this laboratory have been concerned with the pathogenicity for animals of selected, antigenically similar strains of encephalomyocarditis (EMC) virus. During the course of this work, necrosis of the adipose tissue of the retroperitoneum and epididymal fat tags was noted in adult mice infected with many of the EMC virus strains under investigation. Since it seemed likely that these changes were the result of retroperitoneal seepage of digestive enzymes released from the pancreas, this organ was examined histologically.

A lesion of the pancreas is found in EMC-infected mice the carcasses of which exhibit necrosis of retroperitoneal adipose tissue. It consists of coagulation necrosis of acinar cells associated with interstitial oedema and a scant infiltrate of inflammatory cells (Fig. 1). The lesion occurs independently of virus dosage in animals inoculated by the subcutaneous, intraperitoneal or intracerebral route. Usually the whole organ is affected, although small clusters of acinar cells are occasionally spared. Necrosis of the islets of Langerhans has been noted, but in most animals the islets and lining cells of the ducts are well preserved.

Histological changes in the pancreas are apparent well before the neurological signs characteristic of EMC infec-

tion develop. The earliest alteration recognizable by light microscopy is swelling of the acinar cells; later there is loss of basophilia and vacuolation of the cytoplasm. Some clumping of chromatin of the nucleus occurs; however, the nucleus often appears intact after the cytoplasm has disintegrated. Ultrastructural changes in the pancreatic acinar cells are evident 48 h after the subcutaneous inoculation of 10<sup>6</sup> lethal doses (LD<sub>50</sub>) of virus. The electron micrographs show prominent alterations in the architecture of the ergastoplasm, dilatation of the cisterns of the endoplasmic reticulum and dissociation of ribosomes from their membranes, swelling of mitochondria and vacuolation of the cytoplasmic matrix. So far, virus particles have not been identified within affected tissue.

The acinar cells of the exorbital and endorbital lachrymal glands and the parotid elaborate polypeptide enzymes and thus are functionally similar to the exocrine cells of the pancreas. They also possess comparable morphological features. Coagulation necrosis of these organs is found in infected animals exhibiting pancreatic lesions. The histopathological changes in the three glands are similar and appear to develop concomitantly. However, as will be discussed here, necrosis of the lachrymal gland is observed

Fig. 1. Representative histological section of pancreas of adult mouse inoculated subcutaneously with  $10^4$  LD<sub>50</sub> of 1138-E strain of EMC virus and killed 72 h later. Note the necrosis of acinar cells, the interstitial oedema and the absence of an inflammatory cell infiltrate. Scattered clusters of intact acinar cells and an islet of Langerhans can be seen.

in mice infected with an EMC strain (1138-M) which causes no changes in the pancreas or parotid.

Titration of the pancreas and exorbital lachrymal glands of subcutaneously inoculated animals have been carried out to determine their virus content. These studies have been complicated by early viraemia and the occurrence of auto-interference at low tissue dilutions. Within 48 h the two organs contain virus in amounts ( $10^4$ – $10^6$  tissue culture LD<sub>50</sub>) which usually exceed the quantities found in other parenchymal organs and blood. The parotid gland has not been tested because a clean dissection of this organ in the mouse is difficult.

Table 1 summarizes data on the occurrence of necrosis of retroperitoneal adipose tissue in adult mice receiving EMC virus having different origins and passage histories. Each of the viruses was tested in groups of mice at decimal dilutions throughout its infectivity range and the animals were killed when moribund. Typical alterations were found in adipose tissue of mice receiving most, but not all, of the virus strains tested. Although histological studies were not carried out routinely in this survey, the association of gross evidence of necrosis of retroperitoneal adipose tissue with the lesion of pancreas is well established.

Studies with two sub-strains recovered from the same 'wild' source<sup>1</sup> suggest that the ability of a virus to cause the glandular lesions is altered by the manner in which it is passaged. A sub-strain (1138-E) transmitted 11 times as a homogenate of brain, intracerebrally, consistently produces coagulation necrosis of the three glands, whereas a second sub-strain (1138-M) passaged 20 times as homogenized heart, intraperitoneally, occasionally causes lesions of the lachrymal gland but not of the pancreas and parotid. The first sub-strain is highly neurotropic in mice; the second causes severe myocarditis but few, if any, neurological signs.

Table 1. OCCURRENCE OF NECROSIS OF RETROPERITONEAL ADIPOSE TISSUE IN MICE INFECTED WITH SELECTED STRAINS OF EMC VIRUS

Virus strain	Passage		Necrosis of adipose tissue
	Mice Route—times	L cell Times	
EMC-M*	10—c. 80	None	V
EMC-M	10—c. 80	5	O
Mengo	Many†	None	N
1138	10—2	None	V
1138-E	10—11	None	O
1138-M	10—20	None	N

\* Decimal dilutions of virus preparations inoculated subcutaneously throughout infectivity range into 13- to 14-week-old male mice.

† Details of passage history not known. 10, brain passaged intracerebrally; IP, heart passaged intraperitoneally; O, consistent finding; V, variable finding; N, never observed.

Several lines of evidence support the conclusion that the lesions are a consequence of EMC virus infection and not the effect of some extraneous substance or unrecognized infectious agent: (1) they are produced by virus strains which have been passaged in several different laboratories using cell cultures or animals or both; (2) they are caused by isolates purified in cell cultures by the plaque technique; (3) they occur with equal severity over a wide range of virus dosage; (4) they do not develop when a virus strain which consistently induces necrosis of the pancreas (1138-E) is used in a mouse neutralization test with antiserum prepared against a strain which does not cause the lesion (Mengo); and (5) they are not found in control mice inoculated with tissues from animals and cell cultures.

All observations so far indicate that the alterations in adipose tissue are due to release of pancreatic digestive enzymes into the retroperitoneal space. The pancreatic lesion and resulting exocrine insufficiency may account for the diarrhoea which I have noted repeatedly in EMC-infected mice during the terminal stages of illness. A non-purulent conjunctivitis also has been observed in some infected animals; histological examination of the eyes and their accessory structures has failed to reveal any cause other than necrosis of the endorbital and exorbital lachrymal glands.

Lesions of the pancreas and parotid glands occur in adult mice infected with Group B Coxsackie viruses<sup>2-4</sup>. Pancreatic lesions have been described in mice receiving certain strains of the virus of foot-and-mouth disease<sup>5,6</sup>. The histopathological alterations in the pancreatic acinar cells produced by members of these two groups of small RNA viruses (picorna viruses) are similar if not identical to those observed in EMC-infected mice.

## CHANGES IN THE SULPHYDRYL AND DISULPHIDE GROUPS IN BEEF MUSCLE PROTEINS DURING HEATING

By PROF. R. HAMM and DR. K. HOFMANN

Institut für Chemie und Physik, Bundesanstalt für Fleischforschung, Kulmbach, Germany, and Institut für Ernährungswissenschaft, Justus Liebig-Universität, Giessen, Germany

CHANGES of sulphhydryl and disulphide groups in muscle proteins and the formation of H<sub>2</sub>S may be important for the taste and texture of canned meat products.

Methods for the determination of sulphhydryl and disulphide groups in beef muscle tissue (*M. longissimus*

dorsi, 5 days *post mortem*), in myofibrils and in actomyosin gels were developed and the changes of these groups during heating were investigated.

The total content of SH-groups present in muscle proteins can be determined by the reaction with AgNO<sub>3</sub>. Ground tissue, myofibrils or actomyosin, containing

approximately 5 mg protein, are suspended in 35 ml. 0.03 M Tris buffer (pH 7.4), and 1 ml.  $10^{-3}$  M  $\text{AgNO}_3$  (excess) are added. After stirring for 60 min at room temperature,  $1.2 \times 10^{-3}$  moles of glutathione (excess) are added to the filtered solution. The excess of glutathione is titrated by means of an amperometric technique using  $10^{-3}$  M  $\text{AgNO}_3$ . By this method we found for muscle tissue from different animals  $8.8 \pm 0.3$  (S.D.), for myofibrils  $9.6 \pm 1.2$  and for actomyosin gel  $8.8$  moles  $\text{SH}/10^4$  g protein. After denaturation by heating, urea or ethanol, the amount of SH-groups reacting with  $\text{AgNO}_3$  is not significantly increased. Therefore, all SH-groups present in the native muscle proteins are able to react with  $\text{AgNO}_3$ .

When the SH-reagent, *N*-ethyl-maleimide (NEM), is used, only a few of the SH-groups reacting with  $\text{AgNO}_3$  (total SH) can be detected. Ground tissue, myofibrils or actomyosin gel, containing approximately 100 mg protein, is suspended in a mixture of 5 ml. 0.1 M phosphate buffer (pH 6.0) and 5 ml.  $2 \times 10^{-3}$  M NEM (excess). The suspension is shaken for 120 min at 25° C (thermostat) and then centrifuged (14,000g, 5 min) after deproteinization with TCA. The amount of NEM which has not reacted is determined by photometric measurement of the absorption at 300 nm. By means of this technique, we found in myofibrils only  $3.5 \pm 0.1$  moles  $\text{SH}/10^4$  g protein. After denaturation (heating, urea, ethanol, TCA), the amount of SH-groups reacting with NEM increases considerably.

The presence of  $\text{O}_2$  (air) has no influence on the amount of SH-groups reacting with  $\text{AgNO}_3$  or NEM under the conditions used. The amount of disulphide present in tissue, myofibrils or actomyosin can be determined after reduction by  $\text{NaBH}_4$ , which has been introduced into the protein chemistry by Moore *et al.*<sup>1</sup>

0.5 ml. 0.6 M  $\text{NaBH}_4$  (dissolved in 8 M urea) is added to 25 mg of the material. After 60 min reaction at room temperature, the excess of  $\text{NaBH}_4$  is destroyed by adjusting the pH of the mixture to 6.4–6.7 with 0.15 M  $\text{HNO}_3$ . The SH-content of the reduced material is determined by reaction with  $\text{AgNO}_3$  as mentioned here. The SS-content is given by the difference of the SH-groups present after and before reduction. In myofibrils, we found  $6.1 \pm 0.3$  moles  $\text{SS}/2$  per  $10^4$  g protein. The total amount of SH-groups in myofibrils after reduction ranged between 13.3 and 14.8 moles/ $10^4$  g protein.

The cysteine and half-cystine group content obtained chromatographically (ion exchange) after hydrolysis of myofibrils in HCl amounted to only 10 moles per  $10^4$  g protein. Other authors have found similar values (8–9 moles)<sup>2,3</sup>. Apparently, a part of cysteine or cystine cannot be recovered after hydrolysis, even after oxidation to cysteic acid. Probably for this reason, Bárány *et al.*<sup>3</sup> could not find SS-groups in myosins. In our opinion, only the titration of SH-groups in the intact protein after reduction with  $\text{NaBH}_4$  will provide the true value of the cysteine and half-cystine group content.

Heating of myofibrils up to 70° C (30 min) results in a strong increase of SH-groups reacting with NEM (Fig. 1). Apparently, heat denaturation causes an unfolding of the peptide chains and, therefore, a release of reactive SH-groups which before were hidden within the folded structure of the native protein.

The amount of SH-groups of myofibrils reacting with  $\text{AgNO}_3$  is not affected by heating (30 min) up to 70° C (Fig. 2). This is intelligible because all SH-groups in the native protein are able to react with  $\text{AgNO}_3$  under the experimental conditions used. From this result we can conclude that the process of heat coagulation of beef taking place between 50° and 60° C (ref. 4) is not accompanied by formation of new disulphide bonds between the protein molecules. But by heating myofibrils up to the temperatures which are commonly used for canning meat (110°–120°), the amount of SH-groups reacting with  $\text{AgNO}_3$  is considerably decreased (Fig. 2). This effect is greater in the presence of air than under nitrogen. The

decrease of SH-groups at high temperatures is apparently due to an oxidation process which cannot be completely eliminated by treatment under  $\text{N}_2$ , because it is not possible to remove all the air from the tissue or the myofibrils. In actomyosin gels, however, heating under  $\text{N}_2$  does not result in any significant decrease of SH-groups; in this case the air can be almost completely removed.

If myofibrils heated at 120° C for 30 min are treated with  $\text{NaBH}_4$ , almost the same amount of SH-groups reacting with  $\text{AgNO}_3$  is found after reduction as in the reduced unheated myofibrils (Table 1). From this result it is clear that the decrease of SH-groups by heating under these conditions is caused for the most part by oxidation to SS-groups. The increase in the toughness of meat known to be caused by prolonged cooking may be due to such a formation of intermolecular disulphide linkages between the peptide chains of the actomyosin.

Table 1. CHANGES OF SH- AND SS-GROUPS DURING HEATING OF MYOFIBRILS AT 120° C FOR 30 MIN

Unheated samples	SH Moles per $10^4$ g protein	SS Moles/2 per $10^4$ g protein	Heated under	SH Moles per $10^4$ g protein	De-crease %	SS Moles/2 per $10^4$ g protein	In-crease %	S+SS de-crease %
7.2 ( $\pm 0.2$ )	6.1 ( $\pm 0.2$ )		Air	4.8 ( $\pm 0.2$ )	40	8.3 ( $\pm 0.3$ )	35	7
			$\text{N}_2$	5.4 ( $\pm 0.3$ )	25	7.8 ( $\pm 0.3$ )	20	6

However, if the myofibrils are heated at 120° C for a longer time, for example, for 5 h, the amount of SH-groups determined after reduction by  $\text{NaBH}_4$  is considerably less than in the reduced unheated samples (Table 2). Therefore, some SH- and SS-groups are destroyed under these conditions of heating.

Of all the reactions which may be responsible for the destruction of SH-groups, the formation of  $\text{H}_2\text{S}$  comes first into question. For the determination of  $\text{H}_2\text{S}$  released during heating, we modified the method of Marbach and Doty<sup>4</sup>. The sample (2 g) is heated under  $\text{N}_2$  in a closed apparatus; the  $\text{H}_2\text{S}$  formed passes into a trap containing

Fig. 1. Effect of heating (30 min) myofibrils on the amount of SH-groups reacting with NEM.

Fig. 2. Effect of heating (30 min) myofibrils on the amount of SH-groups reacting with  $\text{AgNO}_3$ .

Table 2. CHANGES OF SH- AND SS-GROUPS DURING HEATING OF MYOFIBRILS AT 120° C FOR 5 H

Heated under	SH Moles per 10 <sup>6</sup> g protein	SH Decrease %	SS Moles/2 per 10 <sup>6</sup> g. protein	SS Increase %	S-S decrease %
Air	2.8 (±0.3)	61	7.1 (±0.5)	16	25
N <sub>2</sub>	4.8 (±0.3)	33	6.8 (±0.5)	11	13

Note: the percentage values are related to the values for the unheated samples (compare with Table 1).

NaOH and is determined by photometric measurement (870, 740 nm) of the colour developed after reaction with *p*-amino-dimethyl-aniline and FeCl<sub>3</sub> in HCl. Mercaptans did not interfere with this reaction. As Fig. 3 shows, the formation of H<sub>2</sub>S from myofibrils starts at about 80° C and increases exponentially with rising temperature. The formation of H<sub>2</sub>S increases with increasing time of heating. Heating of the total muscle tissue up to 120° C for 30 min caused the formation of 18.4 and 19.3 µg H<sub>2</sub>S/g protein. This is almost the same as the amount of H<sub>2</sub>S formed by heating the myofibrils (18.7 and 16.8 µg). Therefore, almost the total amount of H<sub>2</sub>S released by heating originates from the structural proteins and not from any water-soluble substances, such as cysteine, present in the tissue. After blocking the SH-groups of the native myofibrils by reaction with AgNO<sub>3</sub>, and also by NEM, heating at 120° C no longer causes the formation of H<sub>2</sub>S. These results show that H<sub>2</sub>S originates from the easily reacting SH-groups of the structural proteins and not from SS-groups or methionine. Fraczak and Pajdowski<sup>6</sup> and recently Mecci *et al.*<sup>7</sup> have suggested that the H<sub>2</sub>S developed during the heating of meat may originate from the SH-groups of the muscle proteins; our experiments demonstrate for the first time that this is indeed the case. All the results reported here could also be obtained with actomyosin.

As our results show, heating up to 70° C causes an unfolding of the actomyosin molecules. At higher tempera-

Fig. 3. Effect of heating (30 min) on the formation of H<sub>2</sub>S from myofibrils

tures, an oxidation of SH- to SS-groups occurs. During longer heating at high temperatures, H<sub>2</sub>S is also formed and this originates from the free or easily reacting SH-groups of actomyosin.

## AGREEMENT BETWEEN CARCINOMA EXPERIMENTS IN VIVO AND LOW-ENERGY X-RAY IRRADIATION OF THE METALLOPROTEIN CARBONIC ANHYDRASE

By DR. N. W. H. ADDINK

Philips Research Laboratories, N. V. Philips' Gloeilampenfabrieken, Eindhoven, The Netherlands

A PHENOMENON characteristic of carcinoma is the sub-normal zinc-level of whole blood of the patients<sup>1</sup>. In earlier papers this sub-normal level has been related either to a decreased content of carbonic anhydrase present in the erythrocytes or to this metallo-protein containing sub-normal zinc<sup>2</sup>. Because of the fact that there have been found significant changes in the zinc-level of blood and urine during and after radiotherapeutic treatment (see hereafter: experiments *in vivo*) it was of interest to examine the influence of X-rays on carbonic anhydrase.

Destruction by X-rays of a metallo-protein in general can be effected, for example, by irradiating into the *K*-absorption band of the metal. Two processes will then occur: that of fluorescence and that of the Auger effect. In both cases important changes regarding the (outermost) valency electrons occur, because the latter have to fill electron holes in the *K*-, *L*-shells, etc. This means that the metal atom can be freed from the organic protein molecule by irradiation of one of the absorption bands of the metal. The metal is then brought into solution in the ionic form.

When a solution of the zinc protein in water is irradiated with a continuum of X-rays, the shortest wave-length being larger than that of the *K*-absorption band of the metal (1.3 Å), there will be scarcely any absorption of the

irradiated energy by zinc. However, by increasing the supply voltage of the tungsten tube, that is, using wave-lengths just below the edge of the *K*-absorption band of zinc, such wave-lengths are absorbed by the metal, and this is freed from the residual organic molecule in the way described here. The higher the operating voltage of the tube, the shorter the minimum wave-length of the continuum, and the greater the chance of freeing zinc.

This effect is illustrated in Fig. 1, which shows how irradiation with the highest energy (case c) releases the zinc in a short time. Using wave-lengths just below the edge of the *K*-absorption band of zinc (curve b), one can also bring about a relatively rapid dissociation. But a very slight and slow-going dissociation occurs if one chooses the tungsten-tube operating voltage 1–2 kV lower (curve a).

It is worth noting that the dissociation processes are of a monomolecular nature. A reaction of the same kind occurs when vitamin B<sub>12</sub>, which contains cobalt, is irradiated.

It should also be noted that only the firmly bound zinc is affected by the releasing process<sup>3</sup>. One should realize that of the zinc which carbonic anhydrase contains, two-thirds is loosely bound, that is, separable by shaking with dithizone<sup>4</sup>, while the remaining one-third is firmly bound, that is, not separable by means of shaking with dithizone.

Fig. 1. Abscissa: time of irradiation (h); X-ray tube: a, 9 kV, 20 m.a.m.p., corresponding to 4,700 r./min.; b, 10.5 kV, 20 m.a.m.p., corresponding to 8,000 r./min.; c, 50 kV, 18 m.a.m.p., corresponding to 200,000 r./min. Height of the irradiated specimen: 15 mm; stirring of the solution each 15 min; irradiated surface 4.4 cm<sup>2</sup>; distance X-ray tube to specimen in all cases 8 mm (Philips X-ray spectrograph PW 1520). Ordinate:  $\mu$ g of firmly bound zinc present in a solution of 10 ml. water containing 10 mg of CO<sub>2</sub>-anhydrase after irradiation

It is the latter part which can be released by irradiation with X-rays.

It is of interest to point out here that as a result of the irradiation the activity of the enzyme (that is, the release of carbon dioxide gas from an HCO<sub>3</sub><sup>-</sup> solution) diminishes as the content of firmly bound zinc decreases, as is shown in Table 1.

From these experiments two conclusions can be drawn: (1) X-ray irradiation initiates the effect of bringing firmly bound zinc into the soluble ionogenic form. (2) The activity of the enzyme carbonic anhydrase is correlated with its content of firmly bound zinc (compare also ref. 8).

Wolff<sup>8</sup> has shown that within 24 h after radiotherapy of carcinoma patients the serum zinc of blood increases from 1.1 p.p.m. to 1.6 p.p.m., whereas after 48 h the zinc content falls back to its original value. This result can also be ascribed to releasing the firmly bound zinc.

In experiments carried out in co-operation with Dr. L. J. P. Frank, I have shown that during prolonged radio-

	Table 1 Content of firmly bound zinc present in 10 ml.	Activity (= $\mu$ equiv. H <sup>+</sup> / sec/mg CO <sub>2</sub> -anhydrase) pH range = 6.6-6.4 (ref. 4)
<b>Solution A</b>		
Not irradiated	1.25 $\mu$ g	41.5
After 1 h irradiation (10.5 kV, 20 m.a.m.p.)	0.84 $\mu$ g	8.25
After 4 h (the same)	0.20 $\mu$ g	2.5
<b>Solution B</b>		
After 1 h irradiation (50 kV, 10 m.a.m.p.)	0.00 $\mu$ g	0.2

**Solution A:** a white preparation obtained from Koch Light laboratories; content of firmly bound zinc 0.125 per cent; 1 mg dissolved in 10 ml. water.

**Solution B:** a yellow-greyish preparation from the same firm; content of firmly bound zinc 0.145 per cent; 0.4 mg dissolved in 10 ml. water; this solution showed an activity of 20.

therapeutic treatment (mammary cancer) the zinc content of urine (X-ray fluorescence analysis; bromine as internal standard) can increase from 0.5 p.p.m. to 1.5 p.p.m., which means that again zinc has been brought into the ionogenic form.

In cases where the zinc content of whole blood of carcinoma patients is extremely low, radio-therapeutic treatment does not increase the zinc content of the patients' urine. This is in accordance with experiments carried out together with Dr. H. J. v. d. Berg (unpublished results), showing that carbonic anhydrase prepared from the blood of these patients<sup>9</sup> does not contain any firmly bound zinc.

It is known that one-third of the total zinc amount in whole blood is in the firmly bound state<sup>3</sup>. In earlier work by Addink and Frank<sup>1</sup> it was stated that in severe cases of carcinoma the lowest value of whole blood zinc amounts to 4.4 p.p.m.: a decrease of one-third compared with the 6.5 p.p.m. found for healthy patients. Once again this indicates that firmly bound zinc is absent in such severe cases of carcinoma.

As such patients remain living over a certain period of time, there must be some firmly bound zinc present; but these small quantities are not detectable chemically. One should keep in mind that according to Roughton<sup>7</sup> blood contains at least forty times the required quantity of carbonic anhydrase.

## A THEORY ON THE MECHANISM OF CARCINOGENESIS BY SMALL DEOXYRIBONUCLEIC ACID TUMOUR VIRUSES

By PROF. LEO SACHS

Section of Genetics, Weizmann Institute of Science, Rehovoth, Israel

THE small DNA tumour viruses polyoma, SV40, papilloma and adenoviruses, contain an amount of DNA that can code for only a small number of proteins. Thus the DNA of polyoma, with a molecular weight of about  $3 \times 10^6$  (ref. 1), has about 4,500 nucleotide pairs, and these can code for about 1,500 amino-acids. Since part of this DNA codes for the viral coat protein, and there may be late functions associated with virus development which inhibit cellular DNA synthesis<sup>2</sup> prior to cell lysis, the amount of DNA which remains to initiate carcinogenesis could only be enough to code for a few functions. The purpose of this article is to show that two virus coded functions can be sufficient for carcinogenesis, that the postulated mechanism of carcinogenesis by these two functions is in agreement with all the

present experimental findings, and to indicate the possible application of these findings to carcinogenesis by hydrocarbons.

Experimental results on cell-virus interactions with these viruses can be divided into six main categories.

(A) Early RNA and early protein are synthesized during virus development, before the synthesis of viral DNA<sup>3</sup>.

(B) A nuclear tumour antigen is synthesized early during virus development<sup>4</sup>.

(C) All tumours synthesize a transplantation, presumably cell surface, tumour antigen. For both the nuclear and the transplantation tumour antigen, different tumours induced by the same virus have the same antigen, and different viruses induce the synthesis of different antigens<sup>5</sup>.

(D) Virus infection can lead to an induction of cellular DNA synthesis<sup>6</sup>.

(E) The cell-virus interaction can result either in the development of virions and cell lysis, or it can directly and rapidly induce the transformation of normal cells to tumour cells<sup>7</sup>.

(F) Tumour cells generally do not produce detectable virus<sup>8</sup>.

(A) has been established for adenovirus and polyoma, (B) for SV40 and adenovirus, nuclear localization most clearly with SV40, (C) for polyoma and SV40, (D) for polyoma, and (E) and (F) have been most extensively established for polyoma.)

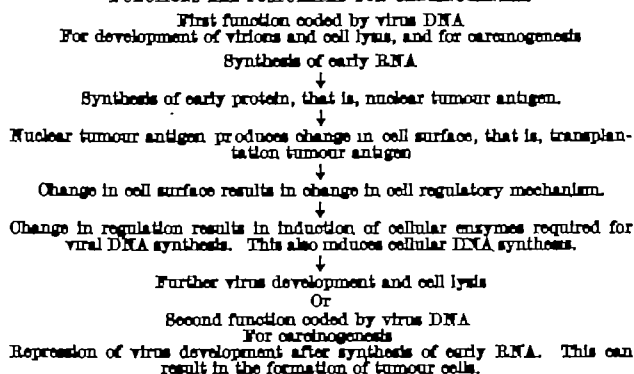

The proposed theory suggests that the two virus coded functions which can explain all these findings are the synthesis of RNA which serves as messenger for the early protein, and a function which represses further virus development after synthesis of this early RNA.

Both the early protein and the nuclear tumour antigen seem to be synthesized at about the same time, and it is suggested in the present hypothesis that the nuclear tumour antigen is the early protein. All virus-induced tumours possess a transplantation tumour antigen, and it is suggested that the nuclear antigen is responsible for the synthesis of the transplantation antigen. This suggestion predicts that the nuclear antigen has enzymatic activity. The synthesis of transplantation antigen can be taken as an indication that there has been a change of the cell surface in comparison to non-infected normal cells. It is assumed that this change in surface changes the cellular regulatory mechanism so as to transform normal cells into tumour cells. The maintenance of the virus-induced cell surface change in the transformed cells, as shown by the continued presence of the transplantation antigen in the tumour cells, would then permit the maintenance of the changed regulatory mechanism. It would follow from the finding that nuclear tumour antigen can be synthesized after virus infection in the presence of inhibitors of DNA synthesis<sup>9</sup>; that the suggested change in cell surface regulation can occur without viral DNA replication. The synthesis of a tumour antigen in the nucleus is presumably due to the fact that virus synthesis takes place in the nucleus.

The suggestion that viral DNA directly codes for the nuclear tumour antigen explains the differences in antigen induced by different viruses. If this assumption of direct coding proves to be correct, the maintenance of nuclear antigen in the tumour cells<sup>10</sup> would be a convincing argument in favour of the assumption<sup>11</sup> that there can be an integration of viral DNA in the tumour cells. The integrated DNA would then be the nucleotide sequence that codes for the nuclear tumour antigen. It would thus be of considerable importance to isolate early RNA, and to characterize it regarding messenger activity for nuclear tumour antigen and for complementarity to virus DNA. It would also be of considerable value for further investigations to have mutants of the same virus that induce the synthesis of different nuclear antigens. The possibility of finding such mutants is suggested by the observation of differences in transplantation tumour antigen induced by different strains of polyoma<sup>12</sup>, and the production of further mutants of this type, together with a marker such as temperature sensitivity<sup>13</sup>, would be highly desirable. Tumour antigens would therefore seem to be the most suitable virus-induced markers<sup>14</sup> for experiments on the possibility of marker rescue in virus-induced tumour cells.

Another finding which has to be explained is the induction of cellular DNA synthesis as a consequence of virus infection, which occurs before the repression of cellular DNA synthesis that precedes cell lysis. It can reasonably be assumed that the amount of viral DNA is not enough to code for all the enzymes required for virus synthesis, so that an induction of cellular enzymes would be required for virus development. The inhibition of polyoma virus synthesis after pre-treatment of cells with mitomycin<sup>15</sup>

Table 1. SEQUENCE OF EVENTS THAT RESULT EITHER IN THE DEVELOPMENT OF VIRIONS AND CELL LYSIS, OR IN CARCINOGENESIS. TWO VIRUS CODED FUNCTIONS ARE POSTULATED FOR CARCINOGENESIS

can also be explained in that the pre-treatment prevents the synthesis of cellular enzymes required for virus development. It is assumed that the change in cell regulatory mechanism induced by the change in cell surface results in the synthesis of cellular enzymes required for virus DNA synthesis. This change in regulation could then also result in the induction of cellular DNA synthesis. This predicts that there can be an induction of cellular DNA synthesis without the replication of viral DNA. This suggested mechanism for the induction of cellular enzymes could also explain the long latent period of these viruses.

It has been shown that the cell-virus interaction can result either in virus development and cell lysis, or in carcinogenesis. Once the messenger RNA for the nuclear tumour antigen has been synthesized, the only other function required to explain this duality in cell-virus interaction is one that represses further virus development. This would then be the second virus coded function for carcinogenesis (Table 1). Expression of this function could result in the growth of tumour cells, whereas a lack of expression would result in further virus development and cell lysis. A low frequency of expression of the virus coded functions required for carcinogenesis and/or the initial transmission of the transformed state to daughter cells, could account for the finding that, even after virus infection of single cell clones, only a minority of the cells undergo the transformation of normal cells to tumour cells<sup>16</sup>.

During growth of the tumour cells after the initial transformation there may be a destruction of the viral genome, or if there is an integration of viral DNA and the nuclear antigen is continuously coded by viral DNA, according to the present hypothesis, the only part necessary to maintain the transformed state would be the nucleotide sequence that codes for the nuclear antigen. Either of these alternatives would explain the finding that the tumour cells generally do not produce detectable virus.

It is of interest to see how far the present theory of carcinogenesis by these viruses can be applied to carcinogenesis by hydrocarbons. It has been shown that carcinogenic hydrocarbons can also induce either cell lysis<sup>17</sup>, or directly and rapidly induce the transformation of normal cells to tumour cells<sup>18</sup>. Tumours induced by these compounds have new transplantation antigens, although in contrast to the situation with virus-induced tumours, a variety of tumour transplantation antigens have been found in tumours induced by any one carcinogen<sup>19</sup>. The maximum number of possible cell surface changes as expressed by differences in tumour transplantation antigens is not known. There are, however, presumably a finite number of possible cell surface changes associated with the change in cell regulation resulting in carcinogenesis. There may thus occasionally be the same change produced by a chemical carcinogen and a tumour virus, and such cross-reacting transplantation antigens have been reported<sup>20</sup>.

With the carcinogenic hydrocarbons it can be postulated that they can directly interact with the cell surface to produce the changes recognized as tumour transplantation antigens, and this may account for the variety of antigens that have been found with the same carcinogen. It would be of considerable interest to know if tumour cells induced by carcinogenic hydrocarbons have a nuclear tumour antigen, as in the case of the virus-induced tumours, and whether a tumour antigen is produced during the process that leads to cell lysis. If the change in the cell surface induced by carcinogenic hydrocarbons can produce changes in regulatory mechanism of the same type as that produced by infection with the tumour viruses, the initial change may also be expressed by an induction of cellular enzyme synthesis. The finding of an induction of some cellular enzymes soon after treatment with carcinogenic hydrocarbons<sup>11</sup> would support the suggestion of a common type of change.

The conclusions drawn here suggest that the further analysis of what have been proposed as the two virus coded functions required for carcinogenesis, and of the changes in synthesis in cells treated with carcinogenic hydrocarbons, could provide crucial evidence on the similarity in the mechanism of carcinogenesis by the small DNA tumour viruses and by carcinogenic hydrocarbons.

## MEASUREMENT OF THE EXCLUDED VOLUME OF PROTEIN MOLECULES BY DIFFERENTIAL SPECTROSCOPY IN THE NEAR INFRA-RED

By WILLIAM C. McCABE and PROF. HARVEY F. FISHER

Veterans Administration Hospital, Kansas City, Missouri, and University of Kansas School of Medicine

WE have observed that a solution of protein in water measured differentially against water produces a negative near-infra-red difference spectrum. This phenomenon is shown in Fig. 1. Curves A and A' represent the phenomenon as observed. Curves B and B' are the spectra of water, presented here for reference. The relationship between the water spectrum and the phenomenon can be seen by comparing each peak of the spectra. The detailed peak-for-peak correspondence is apparent. Curves A and A' are negative water spectra to a very close approximation.

The apparent anomaly in the difference spectrum of bovine serum albumin (BSA) at  $1.7\mu$  is in the region of the first overtone absorption of the C—H stretching frequency in proteins as shown by Hecht and Wood<sup>1</sup>.

A model system (Fig. 2) is proposed to account for the phenomenon observed. The excluded volume, represented in this scheme as a difference, will, in effect, cause a dilution of the solvent (water) in the sample cell. In regions of the spectrum where the extinction of the solvent far exceeds that of the solute, the absorption will be greater in the reference cell than in the sample cell, and a negative difference spectrum will result. This excluded volume can be represented by the volume occupied by the solute in solution.

If this phenomenon is a consequence of volume excluded to the solvent by the solute, then the following criteria should be met. (a) The total absorption of each peak in

the water spectrum of the sample cell should be decreased and the resultant difference spectrum should represent a negative water spectrum. (b) All solutes, regardless of composition, should give a negative difference spectrum, since all of them occupy volume. (c) Where the volume of a solute is known, the amount of exclusion should be predictable.

Satisfaction of criterion (a) was demonstrated in Fig. 1. Satisfaction of criterion (b) is shown in Fig. 3, where the difference spectra of a number of different solutes in aqueous solution versus water are represented. (The near-infra-red spectra of water and aqueous salt solutions have been studied previously by Aschkinase<sup>2</sup> and Collins<sup>3</sup>, among others.) In each case a negative difference spectrum is obtained. This fact itself is significant, since the differences between large polymers (ionic and non-ionic), a non-ionic small organic molecule, and an inorganic salt are quite extreme for any basis of comparison.

Certain anomalies are observed in comparing the difference spectra of each of these solutions to a normal water spectrum. These anomalies are more pronounced for the more ionic and more freely solvated molecules. Most of the deviations from a true negative water spectrum for protein and sucrose solutions can be accounted for by the positive absorption of the solute. This positive absorption acts to decrease the magnitude of the negative difference spectrum in these regions. Since polyvinylpyrrolidone and sodium chloride have no significant absorption, the

anomalies in their exclusion difference spectra must result from either a different kind or a different amount of interaction between the solute and the solvent. This interaction affects the absorption of the solvent in certain regions and thus produces a difference spectrum related more to the solute-solvent interaction than to the volume of the solute. This is quite obvious in the case of the difference spectrum of a solution of sodium chloride.

We may compare protein, sucrose, and sodium chloride in terms of their mode of solvation in aqueous solution. Both sucrose and sodium chloride have relatively small molecular volumes in comparison to proteins but show

Fig. 1. Difference spectrum of BSA versus water. Curve A, 60 mg/ml. BSA versus water; curve B, water versus empty cell; 1-mm path-length cells thermostatted at 16° C. Curves A' and B', same solutions and conditions as for A and B; 1-cm path-length cells. Crystallized and lyophilized BSA was obtained from Sigma Chemical Co. and used without further treatment.

Fig. 2. A schematic explanation of the exclusion phenomenon. The upper line of figures represent the experimental system; the lower line of figures represent the resulting spectral contributions. The hatched areas represent solvent. The irregular open figures represent non-absorbing solute. The algebraic difference between the sample and reference cells is seen to be an amount of solvent equivalent to the volume occupied by solute.

Fig. 3. The difference spectra of several aqueous solutions versus water. Solutions used: ---, 50 mg/ml. BSA; ●, 50 mg/ml. polyvinylpyrrolidone (PVP); ○, 78 mg/ml. sucrose; △, 78 mg/ml. NaCl. The solid line water spectrum is presented for reference. All solutions, except PVP, had the same refractive index at 25° C. The other conditions were the same as those listed for curves A and B in Fig. 1. The PVP used was grade K 80 obtained from Oxford Laboratories, Redwood City, California. It was dialysed to remove salts and lyophilized.

Fig. 4. Excluded specific volume,  $V^{\text{excl}}$ , versus protein concentration. ●, BSA; ○, lysozyme. Experimental conditions are the same as those used for curves A and B in Fig. 1. Crystallized and lyophilized egg white lysozyme was obtained from Sigma Chemical Co. and used without further treatment.

significantly different anomalies in their difference spectra. The fact that a non-ionic sucrose solution gives a difference spectrum closely related to that of a protein solution, while the difference spectrum for an ionic sodium chloride solution is quite anomalous, suggests that solvation of protein molecules differs from that of ionic solutes such as sodium chloride. (We assume here that there is a relationship between the shape of the difference spectrum and the type of solute-solvent interaction.)

To examine the relationship between the volume of a solute and the phenomenon observed (the satisfaction of criterion (c)), solutions of albumin and lysozyme were studied. The results are plotted in Fig. 4 as excluded

specific volume,  $V_{sp}^{rel}$ , versus protein concentration. (We are inferring that this method, though different from Schachman's<sup>4</sup>, measures a similar excluded volume.)  $V_{sp}^{rel}$  was calculated from the following expression:

$$V_{sp}^{rel} = \frac{(A')_{1.44\mu} - (A')_{1.34\mu}}{(A^0)_{1.44\mu} - (A^0)_{1.34\mu}} (1/O)$$

where  $A'$  equals the absorption of the solution at  $\lambda$ ,  $A^0$  equals the absorption of water at  $\lambda$ , and  $O$  equals the protein concentration in g/ml. The protein concentrations were determined spectrophotometrically;  $E_{280}^{1\%}$  (BSA) = 6.60 (ref. 5),  $E_{280}^{1\%}$  (lysozyme) = 26.4 (ref. 6).

The values obtained for  $V_{sp}^{rel}$  appear to be independent of concentration. The average values of  $V_{sp}^{rel}$  for BSA and lysozyme are 0.74 ml./g and 0.68 ml./g respectively. These values are close to the values for the apparent specific volume reported in the literature: BSA = 0.734 ml./g (ref. 7), lysozyme = 0.703 ml./g (ref. 8). This is somewhat more direct evidence of the relationship of this phenomenon to some volume parameter in agreement with criterion (c) and, in fact, suggests that this parameter is

closely associated with the partial specific volume of the protein molecule.

Differential measurement of aqueous solutions in the near infra-red produce negative spectra which are sensitive to both the volume and interaction parameters of the solute. While no definite correlation between the phenomenon observed and these properties can be made at this time, such measurements suggest a useful means of studying these parameters.

## INDUCED CHANGES IN ORIENTATION OF THE CROSS-BRIDGES OF GLYCERINATED INSECT FLIGHT MUSCLE

By DR. M. K. REEDY and DR. K. C. HOLMES

Medical Research Council Laboratory of Molecular Biology, University Postgraduate Medical School, Hills Road, Cambridge AND

DR. R. T. TREGGAR

Department of Zoology, University of Oxford

MYOGENIC fibrillar insect flight muscle is known to perform considerable work by means of small-amplitude oscillations both in life<sup>1</sup> and when glycerinated<sup>2</sup>. The structure of the muscle is exceptionally well ordered<sup>3,4</sup>. Electron microscope studies indicate that the ends of the myosin filaments are connected to the Z line via short connecting filaments<sup>5</sup>. The muscle, even when relaxed, has a much higher elastic modulus than relaxed frog or rabbit muscle<sup>1</sup>. Glycerinated insect flight muscle can be relaxed by bathing it in a solution of adenosine-5-triphosphate (ATP), or thrown into a rigor-like state of increased rigidity and decreased rest length by removal of ATP; the transition between these two mechanical states is reversible. We have studied these two states, and the transition between them, by both X-ray diffraction and electron microscopy. Our results show that the transition is accompanied by a re-orientation of cross-bridges between actin and myosin filaments.

**X-ray diffraction of glycerinated muscle in absence and presence of ATP.** Dorsal longitudinal muscles of the giant tropical water bug *Lethocerus maximus* were used. They were immersed *in situ* in 50 per cent glycerol at pH 7 for several weeks at  $-20^\circ\text{C}$  before use. X-ray diffraction measurements were carried out on sets of fibres mounted in a small 'Perspex' cell modified from a design by Dr. W. Brown, in which the X-ray beam passes through 0.3–0.5 mm thickness of muscle, immersed in the appropriate solution and stretched as required. The whole cell could be cooled; most experiments were performed at  $3^\circ$ – $7^\circ\text{C}$ . Copper  $K\alpha$  radiation was used. A specialized X-ray tube has been built in collaboration with Dr. W. Longley, consisting of a fine-focus rotating anode tube which produces an X-ray source of 1.5 mm  $\times$  0.15 mm loaded with 800 W at 40 kV. The X-ray camera was also novel<sup>6</sup>; it consists of a bent gold-plated glass mirror followed by a bent quartz crystal monochromator, the devices being set so as to produce a common point focus on the film. With this apparatus, 20 min exposures at a specimen-film distance of 12 cm showed the main diffraction features described below. Spacings indicated

on X-ray photographs were measured to  $\pm 0.5$  per cent on a Nikon shadowgraph.

In a simple ionic solution which did not contain ATP (50 mM KCl, 5 mM  $\text{MgCl}_2$ , 4 mM EGTA, 10 mM *tris* at pH 7.15) the muscle is known to be in rigor<sup>3</sup>; we have examined this state at  $5^\circ\text{C}$ . In this solution X-ray diffraction showed a highly characteristic crystalline pattern (Figs. 1a and b). There were a set of equatorial reflexions, arising from a hexagonal lattice of side 530–560 Å (refs. 4 and 8), a strongly sampled first-layer line at  $388 \pm 2$  Å spacing, and further layer lines which can all be indexed as orders of  $2 \times 388$  Å (Fig. 2a). Additional pictures obtained with the apparatus adjusted for high resolving power showed that the 388-Å and 194-Å layer lines had no intensity on the meridian. Moreover, all other low-angle meridional reflexions were weak or absent. On stretching the muscle in rigor by up to 5 per cent over its rest length, there was no significant change in the layer line spacing.

When the solution was changed to one containing 5 mM ATP plus the same ingredients as before, the muscle relaxed, both at room temperature<sup>3</sup> and when cooled, the X-ray diffraction pattern changed dramatically (Fig. 1c). The 388 Å layer line was greatly attenuated and strong meridional spots appeared at 146 and 73 Å (orders of  $146.1 \pm 0.3$  Å; Fig. 2b). The spacings of these spots were likewise unaffected by applying 5 per cent stretch to the muscle. On removal of the ATP by rinsing in ATP-free solution the muscle reverted to the rigor pattern. This cycle could be repeated several times, and could be performed either at room temperature or when the cell was cooled.

**Electron microscopy: experimental.** For electron microscopy, specimens were prepared by adding 1/10 volume of collidine-buffered<sup>7</sup> 25 per cent glutaraldehyde to the solution (at  $0^\circ\text{C}$ ), bathing either relaxed or rigor muscle in the same cell as that used for the X-ray diffraction. Thus fixed specimens could be observed directly in the X-ray beam. The action of the glutaraldehyde in the cold did not affect the X-ray diffraction pattern; the charac-

teristic patterns of relaxed or rigor muscle were still visible after fixation. The specimens were post-fixed in osmium tetroxide, dehydrated in acetone and embedded in 'Araldite' or 'Epon' (Luft's 'Mixture A'<sup>10</sup>); some were stained with phosphotungstic acid in methanol before embedding. Phosphotungstic acid-stained, 'Araldite'-embedded specimens were also observed in the X-ray beam—a method of checking the state of the fixed specimen which was suggested to us by the work of Elliott<sup>11</sup>. They showed the characteristic relaxed or rigor diffraction patterns, at 2 per cent lower meridional spacing, and with much higher intensity in the high-angle meridional reflexions. The spacings, 143.2 and 380 Å, agree with those found by X-ray diffraction in embedded specimens prepared from fresh blowfly (*Calliphora*) flight muscle<sup>11</sup>.

Longitudinal sections of embedded specimens were cut on a Porter-Blum microtome, using a diamond knife, and were stained for 5–20 min with either uranyl acetate<sup>12</sup> or potassium permanganate<sup>13</sup>, followed by 1–5 min additional staining with lead citrate<sup>14</sup>. They were examined in a

Fig. 1. *a*, X-ray diffraction pattern from glycerinated flight muscle of *L. maceratus* in rigor. X-ray beam at right angles to fibre axis. Exposure time 1 h. Note the 388 Å layer line and the effects of the lattice on the zero and first layer lines. *b*, Same as *a*. Exposure time 20 min. Note the weakness of any meridional reflexions. *c*, Same as *a*, but in presence of 5 mM ATP. Exposure time 20 min. Note the strong 146 Å meridional reflexion.

Fig. 2. *a*, Same as Fig. 1*a*. Exposure time 15 h. *b*, Same as Fig. 1*a*. Exposure time 15 h. ATP solution replenished periodically. Orders of 146 Å can be seen together with actin reflexions.

Siemens Elmiskop; magnification was calibrated to  $\pm 1$  per cent, using a method derived from refs. 15 and 16. In insect flight muscle, each actin filament lies midway between two myosin filaments<sup>4,5,6</sup> (Fig. 3). Sufficiently thin sections should therefore sample single layers of filaments, composed of thin filaments only in some regions and alternately thick and thin filaments in other regions. Our 200–400-Å-thick sections contained regions of each type (Fig. 3). Cross-bridges between actin and myosin filaments were clearly visible in single filament layers containing both filament types. The ends of the cross-bridges attached to actin were visible in single filament layers containing actin filaments only. The cross-bridges were in good transverse register across each myofibril, which facilitated measurements of the axial periodicities associated with the bridges. Strong diagonal periodicities resulted from the combined transverse and axial regularity, especially in thick sections (600–1500 Å), and also proved useful in measuring axial periods. The axial periods were obtained as average values over intervals of 10–60 successive repeats, from sections cut with the fibre axis parallel to the knife edge.

**Specimens fixed in rigor.** In specimens fixed in rigor a 380-Å period was easily seen in myofibrils in thick sections; no other period was evident. Thin sections demonstrated a regular polarized arrangement of cross-bridges in single-filament layers containing alternately thick and thin filaments. The bridges were slanted at a mean angle of about  $45^\circ$  to the filament axis; there was appreciable variation about this mean position. The bridges joined the actin in symmetrical pairs, forming actin-centred chevrons which pointed away from the Z band and towards the M line (Figs. 4*a* and *b* and 6*a*). This resembles the polarized 'arrowhead' pattern observed by H. E. Huxley in either *F*-actin or native *I* filaments which had been complexed with heavy meromyosin. The polarization is the same as

Fig. 3. Electron micrograph of one sarcomere of glycerol-extracted *L. marinus* indirect flight muscle, fixed in rigor with glutaraldehyde, post-fixed with  $\text{OsO}_4$ , sectioned with fibre axis parallel to knife edge, double stained with uranyl and lead salts. Inset shows filament lattice. Longitudinal section about 300 Å thick shows single filament layers. 380 Å period associated with cross-bridges in rigor, seen as a series of faint transverse bands, is visible in both varieties (actin-myosin and actin only) of single filament layer. Magnification  $\times 60,000$  (inset  $\times 100,000$ ).

that seen in heavy meromyosin-treated *I* filaments which remained attached to the *Z* band<sup>17</sup>.

In our sections, the chevrons repeated axially at 380 Å (range 370–390 Å), each repeat marked either by a single chevron or by a closely spaced pair of chevrons (Fig. 4a). The axial separation between the chevrons of a pair was 120–180 Å. In regions where the single filament layer included only actin filaments such as those illustrated in Fig. 3, a 380-Å repeat of projections along these filaments was also visible. Although the chevron appearance was less clear, it was sufficiently well indicated to justify the interpretation that these projections represented cross-bridge terminations attached to actin, originating from myosin filaments which had been excluded from the section. Since the 380-Å period associated with cross-bridges was present in sections containing only actin filaments, we supposed it to be the period of the actin attachments. Comparable information about the period of the myosin attachments has not been obtained since single layers of myosin filaments also contain actin. Moreover, variation in the number, angle and apparent

length of bridges has obscured interpretation of the myosin period in rigor.

*Specimens fixed in relaxation.* Sections of specimens fixed in relaxation demonstrated significant structural differences between this state and the rigor state. Thick sections showed two periods within the *A* band. The longer period, again 380 Å, could be identified with a regular dense beaded appearance along the actin filament images in suitably oriented fibrils. A finer period, a regular but faint transverse banding, seemed to be a thirding of the long period on casual inspection; careful measurements of forty to sixty repeats indicated 143 Å as the best value.

Thin sections showed that the polarized configuration of cross-bridges was absent in relaxed muscle. Instead, the

Fig. 4. Electron micrographs of 'Bpon' sections of same material shown in Fig. 3, fixed in rigor, double stained with uranyl-lead (a) and permanganate-lead (b). Field includes centre of *A* band. *Z* bands lie beyond top and bottom of field and provide attachment for two sets of actin filaments which, in this example, just meet at *M* line. The slanted cross-filaments which form actin-centred chevrons pointing toward *M* line (location of thickenings on myosin filaments), which traverses the filament array just above centre of figure. Contrast of Fig. 4a has been enhanced by a copy negative stage. Magnification  $\times 108,000$ .

cross-bridges were essentially perpendicular to the filaments. A regular myosin period of about 140 Å was marked by a varying sequence of fine serrations and bands which characterized the images of the myosin filaments. Many of these features clearly represented cross-bridges parallel to the section plane and extending to meet adjacent actins in the same filament layer; the knobs and bands comprising the remaining features were interpreted as cross-bridges directed out of the plane of the section (Figs. 5 and 6).

In thin sections of relaxed muscle, the 380-Å period was less prominent than in comparable sections of rigor muscle. It was best seen in single-filament layers of actin only, where it was marked by recurrent thickenings or

Fig. 5. Electron micrograph of glycerinated *L. marinus* flight muscle relaxed with ATP-EGTA treatment and fixed in this state by adding glutaraldehyde to bath. Further treatment was as for Fig. 3, except embedding medium, 'Araldite' here, and stain, permanganate-lead here. Field shown is comparable to Fig. 4. In this example, actin filaments from two half-sarcomeres are not touching. Cross-bridges are perpendicular to filaments, and have a 143 Å axial period. Magnification  $\times 120,000$ .

Fig. 6. Diagrams of single layers of actin and myosin filaments showing cross-bridge positions found to be characteristic of (a) rigor and (b) relaxed states of glycerinated insect flight muscle. Thick filaments represent myosin, from which cross-bridges extend towards actin (thin) filaments. In (b), the variation in length of projections represents varying azimuthal positions of bridge pairs around myosin filaments. The exact azimuthal interval is not known but is apparently near  $60^\circ$ .

projections along the filaments. In single-filament layers including both actin and myosin, it was evident only in large samples of a single layer, often only when viewing the micrograph obliquely across the filaments. This period evidently arose because a significant proportion of the cross-bridges directed parallel to the section plane were localized within narrow transverse zones which recurred along an average 380 Å axial repeat. This meshing between the 380 and 143 Å periods could not be readily recognized or explored in the image details of individual actin or myosin filaments.

**Pattern of cross-bridges in relaxation and rigor.** In order to correlate these findings with the X-ray diffraction observations we suppose that the low-angle diffraction pattern with 146 Å period arises from the cross-bridges<sup>4</sup>, whereupon it appears that the cross-bridges of glycerinated insect flight muscle have the following properties:

(a) In relaxation they are attached to the myosin at regular 146 Å intervals, thereby giving rise to the X-ray meridional reflexions.

(b) In relaxation, most of the bridges are at right angles to the filament axis, as seen in the electron microscope and shown by the strength of the 146- and 73-Å meridional reflexions of the X-ray diffraction pattern.

(c) In ATP-free rigor, most of the bridges take up an angled orientation to the filaments, as is demonstrated in the electron microscope and deduced from the weakness of meridional reflexions in the X-ray pattern; meridional intensity is proportional to the strength of electron density variation of the whole structure projected on to the fibre axis, and, if the slope of the cross-bridges is sufficient to cause them to overlap in this projection, the density variation will be greatly reduced or abolished.

(d) In ATP-free rigor, the bridges attach to the actin in symmetrical pairs. These pairs repeat every 388 Å along the filament axis, producing the off-meridional X-ray layer lines and the chevrons seen in the electron micrographs. This repeat distance is very close to the length of one half-turn of the actin helix in glycerinated insect flight muscle, as deduced from the high-angle actin reflexions seen in these diffraction patterns (Fig. 2a, the detailed argument will be presented elsewhere<sup>11</sup>), so that the attachment appears to be determined by the conformation of the actin itself. This is incommensurate with the 146 Å period of myosin in relaxed muscle.

The rigor state is not geometrically perfect, since some cross-bridges are able to link to the same actin at much less than 388-Å spacing, causing the double chevrons, and the angle between bridge and filament is somewhat variable. Nevertheless, the state seems, on the average, fairly crystalline, for the effects of a lattice (which breaks up the X-ray diffraction intensity into a series of spots) are well marked on the zero, first and second layer lines. We have no evidence that the rigor attachment of the cross-bridges changes the length of the myosin filaments themselves; the invariance of the 148 Å meridional spot and 388 Å layer line on stretch indicates that neither the myosin nor the actin filaments are readily extended. X-ray diffraction photographs which include weak 148 Å meridional reflexions have been obtained from rigor specimens after prolonged exposure. This suggests that a regular periodic structure, probably associated with cross-bridge origins along the myosin filaments, is retained in rigor, although other interpretations of this result are possible.

It is attractive to suppose that changes in the position of cross-bridges similar to those shown in Fig. 6 cause the active oscillation of the flight muscle. Although such a mechanism for insect flight muscle activity is hypothetical it gains plausibility from recent X-ray studies of vertebrate muscle which indicate that the cross-bridges move in frog sartorius muscle during isometric tetanus<sup>13</sup>.

This work forms part of a collaborative effort between the Department of Zoology, Oxford, and the Laboratory of Molecular Biology, Cambridge. We thank Prof. J. W. S. Pringle for suggesting the suitability of this muscle for structural studies, and Dr. H. E. Huxley for many valuable discussions. One of us (M. K. R.) is supported by a U.S. Public Health Service post-doctoral fellowship (2-F2-NB-21075-02), and another (R. T. T.) thanks the Agricultural Research Council for support.

## ACRIFLAVIN-INDUCED LOSS OF KINETOPLAST DEOXYRIBONUCLEIC ACID IN *Crithidia fasciculata* (Culex pipiens STRAIN)

By PROF HELENE N. GUTTMAN and ROBERT N. EISENMAN

Department of Biology, University College and the Graduate School of Arts and Science, New York University, Bronx

THE kinetoplast is a DNA-containing, membrane-limited organelle peculiar to protozoa belonging to the Trypanosomatidae<sup>1</sup>. Bodonids contain a similar organelle<sup>2</sup>. This organelle was first demonstrated by Rabinowitch and Kempner<sup>3</sup>, who found, to their surprise, that it was stained by dyes which until then had been thought to stain only nuclei. Almost a generation later Janicki<sup>4</sup> found that kinetoplasts stain as do mitochondria, and, more particularly, as shown in this article, are Feulgen positive<sup>5</sup>. In 1910, Werbitaki<sup>6</sup> and, later, numerous others noted that trypanosomes appeared to lose their kinetoplasts after treatment with certain acridine dyes such as acriflavin. This loss of ability of kinetoplasts to stain with nuclear dyes was thought to indicate loss of the organelle induced by acriflavin and hence the resultant organisms were termed 'akinetoplastic' (AK).

The advent of electron microscopy caused a reassessment of the definition of akinetoplasty when it was shown that acriflavin-treated Trypanosomatidae still retained the kinetoplast envelope<sup>7</sup>; only the electron-dense highly polymerized DNA was no longer evident. In this article, we retain the term akinetoplasty but think of it as a corruption of altered or atypical kinetoplasty, that is, 'AK', where AK corresponds to loss of DNA as monitored by loss of Giemsa or Feulgen stainability or loss of the fine fibrillar electron-dense material in the kinetoplast<sup>8</sup>.

Our experiments were carried out exclusively with Trypanosomatidae, most of which belonged to the genus *Crithidia* (seven species). Although there are quantitative generic differences, the trends are the same. Comprehensive comparison of species and genera and of the kinetics of acquisition of the akinetoplastic state will be reserved for a later report. In this article, we restrict our discussion to the effects of short exposure to acriflavin on the kinetoplasts of *Crithidia fasciculata* (Culex pipiens strain) ATCC 12857.

The organisms were maintained in an undefined medium<sup>9</sup>, grown at 24°–26° C and transferred at intervals

of two weeks. Cells to be used for inoculum were also grown in the undefined medium until they reached near-peak log growth (as assessed by following the growth curve densitometrically). Then 1.0-ml. aliquots of cells plus medium were added to 4.0-ml. aliquots of the same medium which contained neutral acriflavin (0–40 µg/ml.). Samples of cells were collected immediately after inoculation (day zero) and at daily intervals thereafter for a week. The samples were smeared on slides, stained with Giemsa stain and the number of AK organisms counted: 300–600 organisms were counted for each determination, which was then expressed as a percentage of AK.

Fig. 1 illustrates the percentage of AK produced at different acriflavin concentrations. Loss of highly polymerized DNA in kinetoplasts occurs rapidly: by 24 h there is already significant AK, for example, 20.3 ± 1.9 per cent at 8 µg/ml. to a peak of 59.5 ± 2.1 per cent at 24 µg/ml. acriflavin (see also Fig. 1 in ref. 10). It can be seen that after peak AK production in the presence of 24 µg/ml. acriflavin, exposure to yet higher amounts of acriflavin resulted in a smaller percentage of AK. This reduction rather than maintenance of the total percentage of AK when concentrations of acriflavin were used which were greater than that which gives peak AK production is not restricted to one organism: the effect is also shown with *C. fasciculata* (Anopheles strain); *C. fasciculata* (Nöller strain); *C. oncopeltii*; *C. luciliae*; and *C. species from Buryophthalmus*. For all these organisms, peak AK production at 24 h occurred in the presence of 24 µg/ml. acriflavin but absolute percentage AK produced in each case varied with the organism used.

Interpretation of our results depends on considering a direct action of acriflavin with kinetoplast DNA in much the same way as has been described for various effects of acriflavin on isolated, purified, microbial DNA. In such experiments, Lerman measured the effects on DNA X-ray diffraction patterns and viscosity, by the addition of acriflavin<sup>11</sup>. In order to explain his results, he suggested

Table 1. DIFFERENCE IN PERCENTAGE AT (MOLES PER CENT) BETWEEN NUCLEAR AND KINETOPLAST DNA AS A GAUGE OF SENSITIVITY TOWARDS ACRIFLAVIN-INDUCED AKINETOPLASTY

Organism	% AT in nuclear DNA	Kinetoplast DNA	Peak % AK after 24 h†
<i>Crithidia fasciculata</i> ( <i>Oxalis pipiens</i> strain), ATCC 12857	42?*	66?*	59±2.1
<i>O. fasciculata</i> ( <i>Oxalis pipiens</i> strain, Nöller isolate), ATCC 12858	42?*	66?*	49±2.0
<i>O. fasciculata</i> ( <i>Anopheles quadrimaculatus</i> strain), ATCC 12745	46	61	33±5
<i>O. oncopelti</i> , ATCC 12962	47†	66†	41±1

\* Results from ref. 13. The authors did not specify which of the two organisms were used. From our results on the percentage of AK we would expect differences in base ratios of the two organisms.  
† Results from ref. 10, Fig. 1. Other authors (for example, ref. 13) have obtained somewhat different results.  
‡ Our results, which are given here, are compared with differences between nuclear and kinetoplast base ratios in Fig. 2.

that the planar acriflavin molecule is bound to DNA by becoming intercalated into the spaces between the base pairs of the DNA helix so that the plane of the acriflavin molecule lies perpendicular to the helix axis like the filling of a sandwich composed of upper and lower nucleotide pairs with acriflavin in the middle<sup>11</sup>. The results of Tubbs *et al.*<sup>12</sup> suggest some reasons for the differences in acriflavin sensitivity of different organisms and in our case for the preferential attack of acriflavin on kinetoplast rather than nuclear DNA (even though these investigators also worked exclusively with isolated, purified DNA). They showed that binding of acriflavin to DNA was dependent on certain characteristics of DNA including: (a) the base composition. They further speculated that affinity to sites is in this order—AT:AT > AT:GC > GC:GC; (b) the order of the bases; (c) the macromolecular configuration of the DNA.

Of particular pertinence to our results is the finding that acriflavin had greater affinity for high AT-containing DNA<sup>13</sup>. In all cases where it has been charted, kinetoplast DNA (or—as it was termed in some investigations—satellite band DNA) has been shown to have a higher percentage of AT than does nuclear DNA (Table 1). It is then reasonable to consider that kinetoplast DNA is preferentially attacked because of its comparatively higher content of AT. That such a relationship exists is shown by plotting the difference between nuclear and kinetoplast DNA (given in Table 1) against the peak percentage of AK (after 24 h exposure to acriflavin) for three crithidias (Fig. 2).

The questions still remaining unanswered are: (a) What difference between kinetoplast (satellite) and nuclear DNA must exist before there is a preferential attack on the higher AT-containing species? For the genus *Crithidia*, a difference of 10–15 would seem to provide a safe margin for predicting 10–20 per cent AK in 24 h. (b) How can we explain the reduction in percentage AK at very high

Fig. 1. Effect of exposure of *C. fasciculata* (*Oxalis pipiens* strain) to acriflavin on the production of akinetoplasty (AK)

Fig. 2. Relationship between peak percentage AK and magnitude of difference between nuclear and kinetoplast DNA percentage AT (data derived from Table 1). The organisms used were (1) *C. fasciculata* (*Anopheles* strain); (2) *O. oncopelti*; (3) *C. fasciculata* (*Oxalis pipiens* strain); (4) *C. fasciculata* (*Oxalis pipiens* strain, Nöller isolate). Although there is no proof, based on our own experience in distributing trypanosomids to other workers and the close correlation with the results of our experiments with akinetoplasty, we believe that Schildkraut *et al.* (ref. 13) used organism 3.

acriflavin concentrations? Two possibilities seem attractive: (1) At low concentrations of acriflavin, most of the dye enters the cell and eventually becomes intercalated between AT:AT and perhaps AT:GC sites of the kinetoplast DNA. When the concentration of acriflavin is raised, the probability of dye attachment to the surface of DNA<sup>14</sup> is also raised. Since we are dealing with whole cells rather than isolated DNA, it is also possible that some of the dye never reaches its primary sites inside kinetoplast DNA but instead becomes coated on either the cell or kinetoplast membrane, blocking further passage of acriflavin. Blockage would become more profound as acriflavin concentration increases. (2) As concentration of acriflavin is increased, the preference towards attack of DNA containing a higher percentage AT is lost, since enough dye is available to saturate sites requiring binding by intercalation in both nuclear and kinetoplast DNA. When both nucleus and kinetoplast are thus attacked, the cell is moribund and soon lyses, frustrating attempts to count it. The fact that there is a reduction in both optical density (a measure of cytoplasmic mass) and total cell count of cultures containing high levels of acriflavin makes this possibility the more attractive at this time.

## Rotation of the Galaxy NGC 1316 associated with the Radio Source Fornax A

THE peculiar *So* galaxy NGC 1316 lies between the two intense regions of radio emission that constitute the double radio source Fornax A (refs. 1 and 2). The radio centroid lies within the optical boundary of the galaxy. The physical association of the galaxy and the radio source has been put beyond doubt by Arp's discovery<sup>3</sup> of extremely faint optical radiation emanating from curved pathways connecting each radio emitting region with the galaxy. In the immediate vicinity of NGC 1316 these pathways appear to form extensions to the major axis of the main elliptical body of the galaxy. This major axis makes an angle of about  $45^\circ$  with the line joining the radio maxima. Further out the pathways curve sharply and enter the radio emitting region.

A striking feature of NGC 1316 is the presence of a patchy lane of dark absorbing material<sup>4,5</sup> which, as projected on the plane of the sky, appears, at first sight, to lie along its minor axis. Closer inspection shows that this dust lane delineates a spiral pattern. The relationship of these features is indicated schematically in Fig. 1. In this figure the points A and B represent the maxima of radio emission. They are enclosed by the  $4^\circ\text{K}$  brightness temperature contours at 2,650 Mc/s determined with the Parkes 210-ft. radiotelescope by R. M. Price and F. F. Gardner<sup>6</sup>. Between A and B the elliptical outer isophotes of the main body of NGC 1316 are indicated, and within this—in a very schematic way—the spiral pattern delineated by the patchy dust distribution is shown. The dashed lines represent the run of the optical extensions found by Arp.

The Fornax A-NGC 1316 system shows some superficial similarities to that of Centaurus A and the associated galaxy NGC 5128 (ref. 7). Here, too, faint optical extensions to the major axis connect the galaxy with the outer radio regions and a lane of dark material lies along the minor axis of the elliptical<sup>8</sup>. In this case it has been found that the rotation axis of the galaxy, when projected on the sky, lies along the major axis<sup>9,10</sup>. It has been suggested<sup>8,11</sup> that the origin of double radio sources of the kind considered here is connected with violent events of the kind known to occur in the nuclei of some galaxies. The faint optical extensions show that there is some physical connexion between the radio-emitting regions and the

associated galaxy. If this physically connecting pathway—whatever its nature may be—runs between the galactic nucleus and the radio-emitting regions, then, in the case of the Centaurus A system, it emerges from the nucleus of NGC 5128 along its rotational axis. A similar situation exists in the double radio source 3C83 (ref. 12). Here again faint optical extensions coincide with the projected rotational axis.

It is the purpose of this note to point out that the structure of the Fornax A-NGC 1316 system is essentially different.

Spectra of NGC 1316 have been obtained with the nebular spectrograph attached to the 74-in. reflector at Mount Stromlo Observatory. These spectra, on Kodak IIa-O emulsion, have a reciprocal dispersion of 86 Å/mm. They were obtained with the galactic nucleus held fixed on the slit in conditions of good seeing and the slit orientation was different for different exposures. The tilt of the H and K absorption-lines of Ca II (with respect to lines in the spectrum of the comparison arc) has been measured on these spectra. The tilt is maximum when the slit is orientated north-east-south-west, that is, when the slit lies along the major axis of the galaxy. The tilt is zero when the slit lies along the minor axis. The projected rotational axis of NGC 1316 therefore lies along the minor axis, in contrast to the situation found in NGC 5128.

From the broad absorption lines it is not possible to measure a detailed rotation curve, but from the value of  $6^\circ$  which was obtained for the mean tilt when the slit lay along the major axis we find a mean projected rotational velocity gradient of 80 km/sec/kpc for a region extending 1.5 kpc on either side of the nucleus. In deriving these figures a distance of 15 Mpc to NGC 1316 was adopted. Relative to the galactic nucleus the north-east side of the galaxy is approaching and the south-west side is receding.

These observations show that in the immediate vicinity of the galaxy the optical extensions lie in the symmetry plane normal to the rotational axis. It is consistent with observations to suppose that the dark material also lies in this plane which, on this picture, is observed under appreciable inclination. The outermost parts of these 'dark spiral arms' are much more clearly seen on the north than on the south side of the galaxy, and this suggests that the north-west side is nearest to us. It is probable therefore that the spiral pattern of the dark material is rotating with trailing arms.

If there is a pathway connecting the nucleus of NGC 1316 with the radio-emitting regions it is tempting to believe that it lies in the galactic plane, that it is of trailing spiral form and that it is delineated within the main body of the galaxy by dark material and outside it by the optical extensions discovered by Arp.

### Maxima of the Eleven-year Cycle of Solar Phenomena

It is generally accepted that during the last four cycles of solar activity the intensity of the maxima has been steadily increasing.

The term 'solar activity' is generally intended to include all the solar phenomena which vary systematically with the solar cycle of about 11 years<sup>1</sup>. But, as it has been already pointed out<sup>2</sup>, in some cases it would be more correct to use the terms spots activity, faculae activity, plages activity, filaments activity, prominences activity and so on instead of the ambiguous term solar activity.

In this report we point out that it is not accurate to refer to an increase of intensity in the maxima of solar activity in the last four cycles, but only of an increase in the maxima of the sunspot cycle.

In Figs. 1 and 2 we have plotted the yearly means of indices of some phenomena of solar activity for the cycles 16-19.

For a better interpretation of the data shown in Figs. 1 and 2, the mean value  $\bar{I}$  according to the formula:

$$\bar{I} = \frac{1}{3} (I_{M-1} + I_M + I_{M+1})$$

where  $I_{M-1}$ ,  $I_M$ ,  $I_{M+1}$  are the values of the index  $I$ , one year before the sunspot maximum, the year of the sunspot maximum and the year after the sunspot maximum, respectively, has been computed for the cycles 16, 17, 18, 19 separately for the indices considered. In Figs. 3 and 4 the deviations of the  $\bar{I}$  values from their mean are plotted. They are expressed as a percentage of the mean.

A careful examination of the figures shows that, although the intensity of the maxima of the sunspot cycle has been increasing during the past four cycles, the intensity of the maxima of the other phenomena has been almost constant during this period. Furthermore, it seems that the intensity of the maxima of the faculae

Fig. 1. Yearly values of indices of sunspots: 1a, yearly number of sunspots groups lasting for two or more days (Greenwich); 1b, yearly number of sunspots groups seen on one day only (Greenwich); 2, yearly number of sunspots groups (Greenwich); 3, yearly means of the corrected daily area for whole spot expressed in millionths of the Sun's visible hemisphere (Greenwich)

Fig. 2. Yearly means of indices of solar phenomena: 4, yearly means of the daily corrected area of the faculae expressed in millionths of the Sun's visible hemisphere (Greenwich); 5, yearly means of the daily character figure of the H $\alpha$  plages (Zurich, Aroseti); 6, yearly means of the daily character figure of the H $\alpha$  filaments (Zurich, Aroseti); 7, yearly means of the daily character figure of the H $\alpha$  prominences (Zurich, Aroseti); 8, yearly means of the daily projected area of the H $\alpha$  prominences expressed in unit of prominence (Aroseti); 9, yearly means of the daily number of H $\alpha$  prominences (Aroseti)

Fig. 3. Deviations of  $\bar{I}$  values from their mean. The deviations are expressed as percentage of the mean. The indices are numbered according to Fig. 1

cycle, H $\alpha$  plages cycle, and H $\alpha$  prominences cycle has been decreasing during the past three cycles. Even if we confine ourselves to the sunspot cycle, we see that the indices 1 vary much less than the indices 2 and 3.

According to these considerations, the results of some recent investigations concerning the existence of long-

Fig. 4. Deviations of  $I$  values from their mean. The deviations are expressed as percentage of their mean. The indices are numbered according to Fig. 2

term variations in the relationships between ionospheric and solar activity indices<sup>3</sup> may perhaps be reconsidered.

## PHYSICS

### A Suggested Method for Increasing the Resolving Power of a Spectrograph

EARLIER I reported some experiments in which interference phenomena produced by different parts of the diffraction image of a telescope were examined<sup>1-3</sup>. It has been shown<sup>3</sup> that by observing the Airy disk in this way, by means of interference it is possible to resolve finer details in an image than can be recorded from the intensity distribution only. I believe that the same principle may prove of value for increasing the resolving power of a spectrograph.

The principle of such measurements is given in Fig. 1, showing a grating spectrograph with the entrance slit in  $S_1$  and an exit slit in  $S_2$ , after which the light is recorded by a phototube. In front of the slit  $S_2$ , a double image unit is placed composed of a Wollaston prism  $W$  of small deviation, a quartz retardation plate  $Q$  and two polarizers  $P_1$  and  $P_2$  in  $45^\circ$  position. If the two rays produced by the double image prism pass the slit  $S_2$  simultaneously, interference phenomena can be observed, say, by means of a phototube  $Ph$ . The Wollaston prism acts as a Babinet wedge as well, and when it is displaced sideways intensity variations are recorded by the phototube  $Ph$ .

Fig. 1

Each wave-length in the spectrum will appear as two adjacent images, and because of the diffraction image of the spectrograph (and limited resolving power of the grating and finite size of the slits) these will be broad enough to make it possible in both cases for some adjacent wave-lengths to contribute to the light passing the slit  $S_2$ . Let the intensity in the slit of one of these images be  $i_1$  and the intensity of the other image be  $i_2$ , then their contribution to, say, a dark fringe phenomenon is given by:

$$I_{\min} = i_1 + i_2 - 2\sqrt{i_1 i_2} \quad (1)$$

Other neighbouring wave-lengths will give similar contributions and the observed intensity  $I_{\min}(\lambda_0)$  will be obtained as:

$$I_{\min}(\lambda_0) = \int_{-\infty}^{+\infty} J(\lambda) I_{\min}(\lambda - \lambda_0) d\lambda \quad (2)$$

Here  $\lambda_0$  is the wave-length corresponding to the position of the slit  $S_2$  and  $J(\lambda)$  the true intensity distribution in the spectrum.

Expression (2) is of the same type as the well-known integral equation describing the effect of limited resolving power of a spectrograph<sup>4</sup>. The known function  $I_{\min}(\lambda - \lambda_0)$  has, however, a very different shape from that in the conventional theory of resolving power; it can in fact be given different properties by changing the separation between the double images.

In order to exemplify this, a calculated function  $I_{\min}(\lambda_0)$  is given in Fig. 2, where the function  $J(\lambda)$  is given by two adjacent narrow emission lines with a separation  $\Delta$ , which in this case is 7/8 times the separation  $d$  between the double images and 7/16 the size of the diffraction image of the spectrograph assuming a rectangular aperture of the lenses. Fig. 2 gives  $I_{\min}(\lambda_0)$  as well as  $I_{\max}(\lambda_0)$  assuming narrow slits  $S_1$  and  $S_2$ . Without the double image device, scanning the intensity (by turning the

Fig. 2

grating) would give instead the dotted curve of Fig. 2. Moreover, for a singlet the central maximum of the  $I_{\text{min}}$  curve is replaced by a deep minimum. It is evident, therefore, that the method of using interference between different parts of the diffraction image increases the resolution. When making this calculation the intensity distribution within the diffraction image has been assumed to follow a  $(\sin x/x)^2$  curve, where  $x$  is the distance from the centre of the image.

Experiments have been made by using artificial spectral lines made up by two slits polarized in perpendicular directions. The phenomena with the two minima in Fig. 2 for the  $I_{\text{min}}$  curve are clearly revealed in these experiments. So far the instrumental arrangement has made necessary the use of optical systems of the focal ratio  $f/800$  or similar. In our instrument the separation of the beams is one minute of arc only.

Instead of examining the function  $I_{\text{min}}(\lambda_0)$  it may be preferable to measure the degree of visibility\* or only  $I_{\text{max}}(\lambda_0) - I_{\text{min}}(\lambda_0)$ . In the latter case when assuming diffraction according to a  $(\sin x/x)^2$  function only, we find:

$$I_{\text{max}}(\lambda_0) - I_{\text{min}}(\lambda_0) = \frac{4}{\pi} \int_{-\infty}^{+\infty} J(\lambda) \frac{\sin\left(\lambda - \lambda_0 + \frac{d}{2}\right)}{\lambda - \lambda_0 + \frac{d}{2}} \cdot \frac{\sin\left(\lambda - \lambda_0 - \frac{d}{2}\right)}{\lambda - \lambda_0 - \frac{d}{2}} d\lambda \quad (3)$$

In this formula the size of the diffraction image produced by the (rectangular) aperture of the spectrograph equals  $\pi$ .

In Anacapri, we have recently performed some successful experiments where the slit  $S_1$  and photo tube  $Ph$  of Fig. 1 have been replaced by a photographic film. By photographing the solar spectrum in this way, about 6000 Å (with our Babcock grating in fourth order) interference phenomena have been clearly traced in the Fraunhofer lines. In our first experiment the displacement of the two superimposed spectra has been 0.10 mm. The diffraction image of the spectrograph (rectangular aperture) has been 0.12 mm and the image of  $S_1$  on the photographic film 0.03 mm. As can be inferred from Fig. 3, fairly strong interference fringes are present in the continuous spectrum with this arrangement. Probably the limited resolving power of the grating has contributed to the interference phenomenon.

The two spectra in Fig. 3 showing no fringes have been obtained without the Wollaston prism unit, whereas the other two spectra have been taken with different settings of the prism, so that the maxima of the spectrum above have been replaced by minima in the spectrum below. An inspection of the Fraunhofer lines in these two spectra is of great interest. In fact, in the (broad) intensity maxima a single spectrum line appears as a doublet, whereas in the (broad) minima the same line appears as a broad and remarkably dark singlet. Already from this first experiment it seems evident that the effects predicted by me are present, and that the new method of studying

Fig. 3

interference may find interesting spectrographic applications.

However, only extensive experiments will prove if a real gain is obtained with the suggested method. We have to consider that there will be a certain reduction of light, even if the resolving power is increased. The use of 'helium lenses' or similar may prove better in this respect.

I thank Mr. U. Ericson and Mr. Y. Sundblad for valuable help with the preliminary work made in 1964\* and Dr. A. Wyller and Mr. U. Kusoffsky for assistance with the final spectrographic tests.

## The Temperature Scale

Most of the points raised by Prof. J. C. Georgian<sup>1</sup> on the subject of the temperature scale<sup>1</sup> are discussed in Chapter 23 of *A Textbook of Heat* by Allen and Maxwell (1948). The authors refer to a paper by Lewis and Adams<sup>2</sup> making the very point about the dimensions of temperature, specific heat and enthalpy made by Prof. Georgian and proposing a temperature scale that would make  $PV = n\theta$ , where  $n = \text{Avogadro's number}$ . They also discuss a proposal by Planck which seems to have been essentially that now made by Prof. Georgian.

There are, however, certain objections to these proposals. Unlike, for example, the Reynolds number, specific heat and enthalpy are dimensionless only so long as we bear in mind their relationship to water, for they rely for the invariance of their nominal numerical values on the retention of liquid water as the nominal datum. A change of a temperature scale from Kelvin to Georgian would therefore result merely in a change of the value of  $J$  that had to be used in equations relating temperature and heat, unless we were prepared to re-calculate all our specific heat in terms of the relationship of the material to a perfect gas rather than to water. Furthermore, the unit of energy is nominally based on the properties of water (via the definition of the unit of mass), and to proceed to define temperature by invoking another substance altogether (perfect gas) is, I submit, unnecessary and undesirable.

I have already proposed<sup>3</sup> that the calorie and the factor  $J$  could be eliminated simply from temperature equations by the replacement of the Kelvin scale by one having  $100 \times J$  degrees between the ice point and the steam point. I suggested<sup>3</sup> that such a degree should be called the degree Joule. I think that the adoption of such a scale would be easier and more satisfactory than would the adoption of Prof. Georgian's scale, as it would not require any properties to be re-calculated, and I think it would commend itself more readily to practical users.

R. A. LAWS

39 Park Road,  
Watford, Hertfordshire.

I WISH to thank Mr. Laws for refs. 2 and 3.

I was aware of ref. 2 and, in addition, Tolman<sup>4</sup> has an interesting discussion of the dimensions of temperature. Only Tolman wishes to give temperature the units of  $ML^2/T^2$ , that is, allow the molecular mass number (molecular weight) to take on the dimension of mass. However, Porter<sup>5</sup> in his book *Method of Dimensions* explains clearly that the dimension of temperature is indeed  $L^2/T^2$ .

I cannot accept the objection by Mr. Laws to my temperature scale, as in using the MKS system any relationship to water is now irrelevant, because the kilogram mass is defined as a platinum-iridium cylinder deposited at the International Bureau of Weights and Measurements at Sèvres, France. The unit of energy is not based on the properties of water but is defined as one Newton-meter equals one Joule. Hence, all forms of energy will have the same unit, be it heat, mechanical, electrical, chemical, or atomic energy.

The purpose of my temperature scale is to base the scale on the MKS system and, thereby, eliminate the conversion factor  $R$ , in the same manner as the conversion factors  $J$  and  $g$ , have been eliminated in the MKS system.

The proposal of Mr. Laws of adopting a temperature scale in order to preserve the tabulated numbers of  $c_p$  is unnecessary as these values can be readily converted to the MKS system from presently tabulated values in absolute molal units. For example, the National Bureau of Standards has tabulated thermal properties of gases in its *Circular 564* (ref. 6) in dimensionless molal values. Using the MKS temperature scale, it can easily be seen that the ideal gas relation between specific heat at constant pressure and volume becomes:

$$c_p - c_v = \frac{1}{M} \quad (1)$$

where the usual gas constant  $R$  is replaced by  $1/M$ . The specific heat at constant pressure then becomes:

$$c_p = \left( \frac{\gamma}{\gamma - 1} \right) \frac{1}{M} \quad (2)$$

and at constant volume:

$$c_v = \left( \frac{1}{\gamma - 1} \right) \frac{1}{M} \quad (3)$$

The specific heats of gases can be readily determined by dividing the molal values by the molecular mass number  $M$  (molecular weight). I submit the following short table of specific heats at constant pressure for use with the MKS system of units and temperature scale.

Gas	Specific heat $c_p$ at 1 atmosphere and $241.11 \times 10^4$ J/kmole temperature (290° K)
Air	0.1310
Argon	0.0627
Hydrogen	1.717
Nitrogen	0.1252
Oxygen	0.1105
Steam	0.2406 ( $\gamma = 1.3$ )
Carbon dioxide	0.1014
Carbon monoxide	0.1253

If other properties of fluids are required it is possible to re-calculate the properties of fluids very rapidly with the digital computer by substituting the proper coefficients in the appropriate equations.

I have, since writing the original proposal<sup>1</sup>, had a series of thermometers manufactured using Joules per kilomole as a scale; and I am now using them in the laboratory and requiring students to become familiar with them. There was only a nominal surcharge for making these thermometers, and with wide adoption of the scale the price of the thermometers would be the same as present centigrade or Fahrenheit thermometers.

## Gauge Co-ordinate Group of Physical Theory

RECENTLY, a characterization of the larger exceptional Lie groups has been obtained which throws considerable light on what their role may be in physical theory<sup>1</sup>. They are, namely, automorphisms of Clifford algebras of the special form  $\Gamma^{(n,n)} = Q_n \times Q_n$ ; that is, tensor products of normed division algebras  $Q_n$  of  $2^n < 8$  elements. If  $n = 3$ , the groups are  $F_4, E_6, E_7, E_8$  for  $n = 0, 1, 2, 3$ .

The Dirac algebra is  $\Gamma^{(3,3)}$  restricted by reality conditions so that its group is  $D_5$ , the rotation group of six dimensions, isomorphic to the conformal group of spacetime which leaves invariant Maxwell's equations. The way this algebra appears in Dirac's equation (that is,  $\Gamma^* = \{\rho_1 \sigma_i, 1, \rho_3\}$ , with  $\sigma_i, \rho_i$  imaginary quaternions) causes the splitting:

$$D_5 \sim D_4 + A_1 \quad (1)$$

into the Lorentz group and the gauge group of isotopic spin.

The theory of strong interactions<sup>2</sup> has required the enlargement of the gauge group to  $A_5$ , and more recently<sup>3</sup> to  $A_6$ . In the latter case, then, we might expect a role for  $E_6$  with the approximate splitting:

$$E_6 \sim E_5 + A_1 \quad (2)$$

$E_5$  is the group of the sphere  $S_5$ , which is unique in possessing a triality principle. Elsewhere<sup>4</sup> I have given some reasons for believing that it is the group of a classical phase space. It is essential for this interpretation that it involves a cosmological model, that is, at least one of the invariants of the group has a cosmological significance. Without this feature a splitting such as (2) could not have much depth, since it is necessary for the consistency of a theory of measurement. The latter requires three kinds of macroscopic field: (i) metrical (gravitation); (ii) interaction (electromagnetic); (iii) creation ( $C$ -field). It has been shown<sup>5</sup> that the  $C$ -field is necessary for unambiguous interpretation of the 'arrow of time'.

The splitting (2) depends on algebraic specialization of the field of definition of the group, and a crucial question is: What is this specialization? This must provide a source of purely numerical invariants, such as fine structure, mass ratios, etc.

## GEOLOGY

### Significance of Burrowing Structures in the Origin of Convolute Laminæ

THE origin of convolute laminæ in sedimentary sequences has long been disputed<sup>1-4</sup>. The two major hypotheses for the origin of convolute laminæ are: (1) deformation by current drag<sup>1,2</sup>, and (2) deformation by subsequent loading<sup>3</sup>. Exceptionally well-exposed strata of Miocene age, containing convolute laminæ and burrowing structures formed by mud-feeding organisms, occur at Kaiti Beach, near Gisborne, North Island, New

Zealand. The relationship between the burrows and the convolutions presents a new line of evidence regarding the origin of convoluted laminae.

The section of Kaiti consists of rhythmically bedded graded sandstone and mudstone, interpreted to have been deposited largely by turbidity currents. Convoluted laminae are present in most of the sandstone beds. Individual beds containing convolutions are of uniform thickness throughout their exposed length and the convolutions have no apparent directional qualities nor current directional significance.

Burrowing structures formed by marine worms and holothurians (?) are present in most of the mudstone beds. Holothurian (?) burrows are sinuous, cylindrical structures, up to one and one-half inches in diameter, and are approximately parallel to bedding planes. They are concentrated at the base of the mudstone and occur at uniform depths, usually not more than 3-4 in., below the basal sand of the overlying rhythm.

The uniformity of distribution in depth and area of the burrowing structures in almost every rhythm suggests that between the passage of each turbidity current a stable bottom population was developed.

Burrowing structures cut across the convoluted laminae in a dozen or more beds and clearly post-date the convolutions (Fig. 1).

Fig. 1. Tracing made from photograph showing convoluted laminae cut by holothurian (?) burrowing structures

Burrows made by worms are generally straight and show no signs of deformation. In addition, none of the laminae appears to be folded against the massive burrows.

The age relations of burrows and convolutions, the lack of deformation of the worm burrows and the relatively shallow burrowing depth of the holothurians (?) all strongly suggest that current drag rather than subsequent loading formed the convolutions. Local erosion and truncation of antilinal crests of convolutions within a single bed by the overlying turbidite also supports this interpretation.

## Potassium-Argon Ages of some Aberdeenshire Granites and Gabbros

POTASSIUM-ARGON age determinations have been made on specimens of granites and gabbros representative of the 'younger' Caledonian plutonic intrusions of north-east Scotland. Unlike the 'older' igneous rocks these 'younger' intrusions post-date the earlier fold movements and acme of regional metamorphism in the Dalradian schists<sup>1</sup>. The exact relation of the gabbro intrusions to the established sequence of movements and metamorphisms in the Dalradian rocks has received considerable attention<sup>2-4</sup>. It is evident that their emplacement post-dates the large recumbent ( $F_1$ ) fold structures of north-east Scotland (Benff Nappe), the second phase ( $F_2$ ) structures and the static (post- $F_2$ ) climax of regional metamorphism; also the evidence strongly favours deformation of the gabbros by the Boyndie-Buchan group of folds ( $F_3$ ) and is suggestive of their intrusion as a single large sheet<sup>5</sup>.

The potassium-argon ages for three of the basic masses show a spread from 460 to 498 million years. If the gabbros were originally intruded as a single sheet, then the spread of ages can be regarded as due to varying degrees of overprinting caused by metamorphic effects associated with the post-gabbro fold movements ( $F_3$ ). Thus the minimum age of intrusion is that represented

by the results of 486 and 498 million years obtained for the Haddo House mass and the true age could well be somewhat greater. This result is important with respect to the age of the earlier fold phases affecting the Dalradian rocks. Johnson and Harris<sup>6</sup> found that the supposed Arenig rocks of the Highland Border Series are affected by the earliest folds found in the Dalradian schists; this, on the time-scale at present accepted<sup>7</sup>, would mean that the Dalradian recumbent nappe structures were formed more recently than 500 million years ago. On the other hand, the new radiometric evidence strongly suggests that the first and second fold phases in the Scottish Dalradian rocks took place in pre-Arenig times, and emphasizes the doubt as to the precise age of the 'Arenig' rocks of the Highland Border Series. Also geological evidence from Co.

Mayo<sup>8</sup> and Tyrone<sup>9</sup> indicates that the Irish Dalradian underwent pre-Arenig movement and metamorphism.

Bisset<sup>11</sup> was able to divide the 'younger' granites in the area of Aberdeen into an earlier group, which he referred to as the Skene complex, and a later group including the red granites of Bennachie and Hill of Fare. The red granites are clearly members of the late or post-Silurian Newer Granite suite and the dated specimen of Bennachie granite yielded an age of 404 million years. On geological grounds the earlier Skene complex was also stated by Bisset to be a member of the Newer Granite suite and like the red granites is therefore younger than the gabbros. The Skene complex includes dioritic rocks and a variety of granitic types, all of which show complex injection relations with the country rocks, while the later red granites are relatively homogeneous masses with clearly defined sharp contacts. Felsite and lamprophyre dykes cut the Skene complex but not the red granites of Bennachie or Hill of Fare. The dated specimen from the Craigenlow quarry is a type assigned by Bisset to the porphyritic granites of the Skene complex. As a result of recent extensive quarrying, the rock can be seen to represent an advanced stage migmatite which remains as ghosts of an earlier metamorphic foliation. Superposed on the latter, however, is a complex fluxion foliation—the rock having sheared and re-healed repeatedly during movement. These shearing movements have sometimes been sufficiently strong to break up earlier lamprophyre intrusions, so that the latter occasionally occur as xenoliths in the

Table 1

			6.91	1.029 × 10 <sup>-1</sup>	20.5	404 ± 5
			6.91	1.029 × 10 <sup>-1</sup>	19.6	404 ± 5

$\lambda_e = 0.584 \times 10^{-18} \text{ yr}^{-1}$ ,  $\lambda\beta = 4.72 \times 10^{-18} \text{ yr}^{-1}$  Volume of argon-40 (radiogenic) in mm<sup>3</sup> H.T.P.

rock they formerly intruded. The ages of 416 and 414 million years obtained for the Craigenlow specimen are consistent with those geological features which suggest that the Skene complex is an earlier and probably deeper seated member of the 'younger' or Newer Granites than the nearby red granite of Bennachie. It is here suggested that the Skene complex may in some respects be analogous to the Rogart granite in Sutherland which is also an early, deep-seated, member of the Newer Granite suite and has yielded ages of 424 and 416 million years<sup>13</sup>.

The contact relations of the red granites suggest that at the time of their intrusion the temperature of the country rocks was distinctly lower than that of the granites. Elsewhere, for example, at Lochnagar, the mode of intrusion suggests that the country rocks were locally brittle when the red granites of north-east Scotland were intruded. The difference in ages of the Bennachie granite (404) and the Skene complex (416 million years) presumably therefore reflects the cooling history of the country rocks into which the granites were intruded.

ENGINEERING

Measurement of Contact Angles in the Presence of Mass Transfer

Low distillation and absorption efficiencies in gas/liquid contacting equipment have been attributed to liquid film breakdown and underwetting. A study of a model simulating these conditions has resulted in observations of contact angles when mass transfer is occurring.

Results are presented here for the contact angles of water on stainless steel, copper, graphite and 'Perspex' surfaces in the presence of a saturated ethanol/air vapour.

The solid surfaces were prepared in pairs of different roughness and before each experiment were carefully pretreated and dried.

The effect of the ethanol vapour in each case was to cause the sessile drop of water to spread over the surface and the contact angle to be reduced until an equilibrium was reached. This is attributed to the absorption of ethanol by the water droplet causing a reduction in surface energy and to adsorption of ethanol on the solid surface.

Wenzel<sup>1</sup> has shown that, for contact angles measured without mass transfer under isothermal conditions on differing roughened surfaces,  $\cos \theta^1 = r \cos \theta$ , where  $\theta^1$  is the contact angle on a roughened surface and  $\theta$  is the true contact angle on a perfectly smooth surface.

Fig. 4

Fig. 5

Table 1

	Roughness m.	Contact angle Initial	Equilib.	Time to reach equilib.	Spreading coeff. Initial	Equilib.
					dynes/cm	
Copper	5-10 × 10 <sup>-4</sup>	87°	45°	45 min	-68.2	-14.8
	50-60 × 10 <sup>-4</sup>	72°	33°	8 "	-49.6	-7.9
Stainless steel	5-10 × 10 <sup>-4</sup>	60°	35°	25 "	-46.5	-8.7
	50-60 × 10 <sup>-4</sup>	45°	20°	15 "	-18.5	-2.0
'Parapex'	5-10 × 10 <sup>-4</sup>	81°	45°	12 "	-60.6	-14.3
	50-60 × 10 <sup>-4</sup>	78°	15°	10 "	-57.0	-1.65
Graphite	5-10 × 10 <sup>-4</sup>	102°	20°	40 "	-87.0	-2.9
	50-60 × 10 <sup>-4</sup>	145°	18°	15 "	-129.0	-2.4

Fig. 5 indicates that for any particular time before equilibrium is reached, since the absorption rate by the liquid and the roughness ratio for each material are equal, the contact angle is most markedly influenced by the adsorption of ethanol on the solid surface.

## CHEMISTRY

### A New Approach to Desorption of Surface-active Substances at Liquid-phase Boundaries

In order to investigate the kinetics of the formation of adsorption layers at liquid/gas and liquid/liquid boundaries we have made use of the methods of surface tension measurement, including the sessile bubble or drop technique<sup>1</sup>. Furthermore, an attempt has been made to investigate the possibility of desorption from the adsorption layer by replacement of the surfactant solution around the bubble (drop) by a pure solvent in static conditions (without disruption of the bubble or drop and the adsorption layer).

The experiment was carried out in the following way. A special thermostatic optical cell with a device for maintaining liquid flow at a constant hydrostatic pressure is filled with a surfactant solution, in which the sessile bubble is formed. The change in surface tension is then recorded in the usual way (photography with subsequent measurement of the bubble image and calculation of surface tension from corresponding tables). Then, after a given time of surface-layer formation, sufficient pure solvent is slowly pumped through the cell (approximately 3 l. per 20 min.) to remove completely the dissolved substance. The time of such 'washing out' of the cell depends on the rate of solvent flow, solution concentration and cell construction.

Surface tension is constantly recorded during this process of 'washing out' and afterwards. Once this stage of the experiment is over, a new bubble is formed in the washing substrate and the surface tension of the substrate is again recorded.

Using this method we were able to show the desorption of surface-active molecules from adsorption layers. Typical results for sodium oleate are given as an example: in addition to the surface tension curve characterizing the process of desorption (the increase of surface tension from 33.3 ergs/cm<sup>2</sup> for 0.01 per cent solution at 20° C and pH 11.0 to 72.5 ergs/cm<sup>2</sup>), the surface tension value (72.5 ergs/cm<sup>2</sup>) after replacement of the solution by water (at the same pH value) and the surface tension of the washing substrate (72.5 ergs/cm<sup>2</sup>) are very close to the value for pure water under similar conditions.

On the other hand, we were able to show experimentally the irreversibility of adsorption of the macromolecular surface-active substances at the liquid/gas surface using, for example, polyvinyl alcohol. The adsorption layer formed (surface tension of 68.0 ergs/cm<sup>2</sup> for 0.3 per cent solution) does not show any signs of desorption after the replacement of the solution by pure water for a long time (surface tension has not changed after 20 h), while the

surface tension of the washing substrate is greatly increased (72.5 ergs/cm<sup>2</sup>) and corresponds to the value of pure water. It clearly shows that polyvinyl alcohol molecules, in any event for a long time, cannot leave the adsorption layer.

It should be pointed out that the question of reversibility or irreversibility of macromolecular adsorption has been considered theoretically<sup>3</sup>.

Moreover, the suggested method makes it possible to consider the question of adsorption equilibrium at liquid interfaces as a true thermodynamic equilibrium since it enables one to obtain the desired concentration of solution under investigation from two approaches (from lower and higher concentrations).

Besides desorption studies and the problems connected with it, the suggested method opens up great possibilities for research under static conditions of various types of interactions in adsorption layers and makes it possible to carry out successive measurements at the same undisturbed surface (adsorption) layer.

I thank Prof. P. A. Rehbinder for his advice in this work.

### Gas Chromatographic Separation of Stereoisomeric Trichloroheptanes using Organo-clay Complexes

SINCE White<sup>1</sup> has shown that dimethyldioctadecyl ammonium bentonite is particularly suitable as a stationary phase for the chromatographic separation of aromatic and aliphatic compounds, several authors have shown the ability of this material to separate aromatic isomers, for example, xylenes, toluidines, cresols<sup>2</sup>, dichlorobenzenes<sup>3</sup>. The performance of organo-clays was improved by modification with conventional liquid stationary phases<sup>4</sup>.

Here we report the separation of aliphatic stereoisomers of the 2,4,6-trichloroheptane which exists in three forms:

The presence of these isomers in 2,4,6-trichloroheptane has been proved by gas chromatography on 'Apiezon L'-coated capillary column (Fig. 1), the sequence of peaks being: (1) syndiotactic; (2) heterotactic; (3) isotactic form as confirmed by spectroscopic analysis<sup>5</sup>.

In chromatographic columns filled with conventional stationary phases<sup>6</sup> we were not able to obtain any separation of isomers even when a 10 m column with 'Carbowax' as the stationary phase was used, which showed very good

selectivity in separation when two isomeric 2,4-dichloropentanes<sup>7</sup> were used.

On the other hand, an excellent separation was achieved with a 2-m column filled with dimethyldioctadecyl ammonium bentonite modified with 'Apiezon L' (Fig. 2). With this column, in contradistinction to the capillary one, a reversed elution order was observed, the isotactic form appearing first, the syndiotactic form being most retained. The selectivity of organo-clay complexes for this kind of separation may be explained by specific absorption forces of an electronic nature between the sorbate and chlorine atoms of single stereoconfigurations of the solute.

The chromatographic runs were performed on Fractometer 116E (Perkin-Elmer), the separating conditions being as follows: 50 m stainless steel capillary column of internal diameter 0.25 mm coated with 'Apiezon L', column temperature 150° C, nitrogen carrier gas velocity 1.0 ml./min, sample size 0.1 µl., split ratio 1:200, flame ionization detector (Fig. 1).

A typical chromatogram on Fig. 2 was obtained with a column 200 cm long x 0.38 cm bore filled with 15 ww per cent of equal parts by weight of 'Bentone 34' (F. W. Berk and Co., Ltd.) and 'Apiezon L' on 'Celite' (40-60 mesh) prepared according to Mortimer<sup>8</sup> at a column tem-

2,4,6-Trichloroheptane isomer	Relative retention volume at 150°	
	'Apiezon L'	'Bentone 34'
Syndiotactic	0.97	1.23
Heterotactic	1.0	1.0
Isotactic	1.05	0.80

perature of 150° C, a hydrogen carrier gas velocity of 50 ml./min, a sample size of 0.1  $\mu$ l., and a hot-wire conductivity detector.

The relative retention volumes of isomers are given in Table 1. It should be noted that with increasing sample size the elution peaks become asymmetric and the separation factors decrease. In spite of these circumstances it was possible to perform, under proper conditions and column size, preparative separation of 20- $\mu$ l. samples of 2,4,6-trichloroheptane and isolation of pure stereoisomers.

### Relationship between Volume Change on Fusion and the Volume of Defect Formation in Ionic Crystals

THE molar volume change on fusion of an ionic compound,  $\Delta V_{\text{fusion}}$ , is relatively easy to determine. It may be found directly, by observing the change in length of a column of fused salt in a capillary when this is cooled through the freezing temperature, or indirectly by measuring the freezing point of the salt as a function of pressure and applying the Clapeyron–Clausius equation. The literature now contains reliable values of  $\Delta V_{\text{fusion}}$  for the common inorganic salts<sup>1,2</sup>.

It is well known that ionic solids may contain defects of the Schottky (vacant site) or Frenkel (interstitial ion) type, and that migration of these defects gives rise to diffusion and electrical conductance in the solids. Since the individual defects in an ionic crystal bear an excess charge relative to the undistorted lattice, the condition of electrical neutrality requires that a given crystal must contain at least two types of defect bearing opposite excess charge. For each cation vacancy in a stoichiometric crystal containing ions of non-variable valency, there must be either an anion vacancy or an interstitial cation elsewhere in the crystal. In a particular compound, one or other of these possibilities usually predominates; for example, the alkali halides are known to contain cation and anion vacancies<sup>3</sup>, and the silver halides mainly cation vacancies and interstitial cations<sup>4</sup>. In  $\text{CaF}_2$ , the complementary defects are anion vacancies and interstitial anions<sup>5</sup>.

The molar volume of formation of defects,  $\Delta V_{\text{form}}$ , is defined as the volume increase associated with the formation of one mole of each of the complementary defects in an initially perfect crystal.  $\Delta V_{\text{form}}$  is relatively difficult to determine experimentally; values are at present available only for KCl, NaCl, AgBr and  $\text{KNO}_3$  (refs. 6–8). It is found from the isothermal pressure coefficient of the electrical conductivity of the crystal; measurements must be carried out on the pure substance, and also on a sample into which additional defects have been introduced by adding traces of divalent cations<sup>6</sup>. It has been found that, for crystals containing vacant cation and anion sites in equal numbers,  $\Delta V_{\text{form}}$  is about 1.5 times the molar volume of the salt, whereas for silver bromide  $\Delta V_{\text{form}}$  is only about 0.5 times the molar volume. The magnitude of  $\Delta V_{\text{form}}$  relative to the molar volume of the solid,  $V_s$ , therefore gives an indication of the types of defect predominant. (If there were no distortion of the

crystal lattice around each defect,  $\Delta V_{\text{form}}$  would equal  $V_s$  for crystals containing anion and cation vacancies, and would be zero for crystals containing cation vacancies and interstitial cations.)

The purpose of this communication is to point out that there appears to be a proportionality between  $\Delta V_{\text{form}}$  and  $\Delta V_{\text{fusion}}$  for all crystals, irrespective of the types of defect present in the solid (Table 1).

Table 1

Salt	$V_s$ , just below m.p.	$\Delta V_{\text{fusion}}$	$\Delta V_{\text{form}}$	$\Delta V_{\text{fusion}}/\Delta V_{\text{form}}$
KCl	41.00	7.2	67	0.11
NaCl	30.2	7.5	43	0.18
AgBr	31.1	2.5	16	0.16
$\text{KNO}_3$	52.5	1.73	11	0.16

(all volumes in ml.mole<sup>-1</sup>)

The ratio  $\Delta V_{\text{fusion}}/\Delta V_{\text{form}}$  is formally equal to the degree of defect formation (that is, the fraction of lattice sites vacant, or fraction of interstitial sites occupied) which would have to occur in the solid in order to produce a volume change equal to  $\Delta V_{\text{fusion}}$ . It is seen that  $\Delta V_{\text{fusion}}/\Delta V_{\text{form}}$  lies in the range  $0.15 \pm 0.04$  for the four salts for which data exist. The X-ray diffraction work carried out by Levy *et al.*<sup>9</sup> on fused alkali halides showed that the average co-ordination number in salts having the rock-salt structure falls from six to about five on fusion. If this change were brought about by introduction of defects into the crystalline solid, the degree of defect formation required would be about 0.17. This is suggestively close to the figures in the last column of Table 1, and leads me to propose the following rules:

(1) The fusion of an ionic crystal is equivalent to the introduction of disorder into the crystalline lattice to the extent of  $15 \pm 4$  per cent.

(2) The defects introduced on fusion are of the same type as those already present in the crystal below its melting point.

Thus, fused silver halides may be thought of as containing an approximately intact bromide lattice, with 85 per cent of the silver ions occupying normal sites and the remaining 15 per cent on interstitial sites, while fused alkali halides have approximately the rock-salt lattice each with 15 per cent of the cation and anion sites vacant. These pictures are approximate in so far as the vestiges of lattice structure which remain in the melt are insufficient to impart the property of rigidity.

The converse of the above rules may be written:

(3) Those ionic compounds for which  $\Delta V_{\text{fusion}}/0.15$  is less than about one-half of the molar volume have cation vacancies and interstitial cations, or anion vacancies and interstitial anions, as predominant defects in the solid. Those compounds for which  $\Delta V_{\text{fusion}}/0.15$  is about 1.5 times the molar volume contain predominantly cation vacancies and anion vacancies.

This third rule may be the most useful of the three, because it enables us to predict the type of defect present in a solid from a knowledge of its volume change on fusion. This quantity is relatively easy to determine, whereas the determination of  $\Delta V_{\text{form}}$  (on which conclusions as to type of defect have usually been based) requires the difficult and painstaking measurement of the pressure coefficient of the electrical conductivity.

**Relationship between the 3,3',5-Triiodo-L-thyronine Content of Thyroid as determined by a Thin-layer Chromatographic Method and the Biological Potency assayed by a Rat Anti-thiouracil Goitre Method**

In a recent paper<sup>1</sup>, we described a method which could be used for identifying thyroxine in a feeding-stuffs additive; its separation from the other components present in the hydrolysed iodinated protein was effected on paper and on starch-bound cellulose powder thin-layer plates.

If the procedures referred to therein are applied to hydrolysed thyroid, both paper and thin-layer chromatograms are capable of effectively resolving a substance having an  $R_f$  value corresponding to thyroxine as a well-defined spot. The spot with  $R_f$  value corresponding to triiodothyronine is, however, poorly defined on paper chromatograms, but the thin-layer chromatogram shows a distinct spot which can be assessed visually against triiodothyronine standards.

Since it is known that triiodothyronine ( $T_3$ ) makes a far greater contribution than thyroxine ( $T_4$ ) to the activity of thyroid when assayed by the rat anti-thiouracil goitre method, it was thought that the triiodothyronine content of hydrolysed thyroid, as determined by visual assessment of thin-layer chromatograms, should provide some indication of the potency. When two samples of thyroid were examined by this means, the quantity of material in the triiodothyronine position present in one sample was distinctively different from the quantity in the other. The first sample was reported to have one-third of the biological activity of the second when subjected to the rat anti-thiouracil goitre test and we estimated that the spots on the thin-layer chromatograms corresponded to 0.025 and 0.06 per cent of triiodothyronine respectively. A third sample, said to be 'biologically unsatisfactory' (the source and type of bio-assay are unknown), showed only a very faint spot, equivalent to about 0.005 per cent of triiodothyronine.

The conditions necessary to obtain spots well separated from other materials and in good alignment with triiodothyronine standards have been worked out in detail. The hydrolysis and extraction of active materials into *n*-butanol are based on the procedure described by Devlin and Stevenson<sup>2</sup>. Thin-layer plates prepared by the method previously described<sup>1</sup> should be used, and should run at a

temperature greater than 20°C and preferably near to 26°C in the *t*-amyl alcohol and ammonia solvent system described by Barker<sup>3</sup>, special precautions being taken to ensure that the atmosphere is saturated with ammonia. The FFCA reagent of Gmelin and Virtanen<sup>4</sup> is the preferred spray reagent for spot location. The chromatogram is undisturbed by the water-washing necessary to remove excess reagent after spraying. The procedure is improved when a 'blank' enzyme hydrolysate is superimposed on the triiodothyronine standards, so that the hydrolysed sample and standards run in the same environment, as shown in Fig. 1.

This work was undertaken as a result of our membership of Panel 7 of the Joint Committee of the Pharmaceutical Society and the Society for Analytical Chemistry on Methods of Assay of Crude Drugs. The samples of thyroid were selected from those used for work by Panel 7 and bio-assays were supplied by Mr. K. L. Smith of Boots Pure Drug Co., Ltd., Nottingham. Collaborative tests on the method based on these principles is at present being carried out by members of Panel 7 to confirm that the apparent correlation with biological activity can be substantiated on a wider range of samples.

## BIOCHEMISTRY

### Effect of Magnesium Deficiency on Plasma Alkaline Phosphatase Activity

MAGNESIUM activates many enzymes *in vitro*, but very few disturbances in enzymatic activity have been demonstrated during magnesium deficiency *in vivo*<sup>1</sup>. The alkaline phosphatases from various mammalian tissues are among the enzymes known to be activated by magnesium in isolated systems. This communication reports investigations of the effect of magnesium deficiency on plasma alkaline phosphatase activity in the rat.

Two groups of female Wistar albino rats of initial weight 100 g were fed with magnesium-deficient and control diets respectively for 15 days. All animals received an amount of food equal to that consumed by the deficient rats; this gave an initial food intake of 10 g reducing to 8 g/rat/day. Distilled water was provided *ad lib.* throughout the experiment. The magnesium-deficient and control diets were prepared as described previously<sup>2</sup>; their magnesium contents were 0.2 mg/100 g (deficient) and 78 mg/100 g (control). The rats were anaesthetized with ether and killed by bleeding from the heart. Plasma was separated from heparinized blood within 0.5–1 h.

The plasma from each magnesium-deficient rat was divided into two and the magnesium concentration in one portion was raised to normal by adding to it 0.83 per cent of its volume of a magnesium chloride solution containing 165 mg/100 ml. of magnesium. The alkaline phosphatase activity was measured in all samples of plasma, as described by King and Wootton<sup>3</sup>, after standing overnight at 4°C. The measurements were repeated after storage for a further six days to allow ample time for the added magnesium

Fig. 1. Thin-layer chromatogram showing 6 µl. of each of two samples of enzyme-hydrolysed thyroid, A and B, alongside increasing quantities of triiodothyronine ( $T_3$ ). Six µl. of a 'blank' enzyme hydrolysate have been spotted over each spot of triiodothyronine.

to combine with the enzyme. Magnesium concentrations were determined by atomic absorption spectrophotometry<sup>4</sup>.

The alkaline phosphatase activity in the plasma from magnesium-deficient rats was only half that found in the control animals ( $P < 0.001$ ) (Table 1). Addition of sufficient magnesium chloride to restore the magnesium concentration to normal in the plasma from deficient rats raised the alkaline phosphatase activity significantly ( $P < 0.001$  and  $P < 0.01$  after storage for 1 and 7 days respectively), but did not restore it to the level found in the control animals ( $P < 0.001$ ). No consistent difference in alkaline phosphatase activity was observed between the measurements made after storage for 1 and 7 days, indicating that reactivation by the added magnesium was complete after storage overnight.

Table 1. RELATION BETWEEN ALKALINE PHOSPHATASE ACTIVITY AND MAGNESIUM CONCENTRATION IN THE PLASMA FROM CONTROL AND MAGNESIUM-DEFICIENT RATS

Group	Magnesium concentration (mg/100 ml.)	Alkaline phosphatase activity (King-Armstrong units) after storage for	
		1 day	7 days
Control	1.77	40.3	43.9
	$\pm 0.04$	$\pm 3.9$	$\pm 4.4$
Mg-deficient	0.43	20.5	19.5
	$\pm 0.02$	$\pm 3.0$	$\pm 1.9$
Mg-deficient + MgCl <sub>2</sub>	1.87	25.0	23.3
	$\pm 0.04$	$\pm 2.6$	$\pm 2.4$

The values indicate mean  $\pm$  S.E.M.  $n=12$  for control group;  $n=15$  for the other groups.

A reduction in enzymatic activity may be due to either a decrease in the amount of enzyme present or a fall in the rate of operation by a normal amount of enzyme. The increase in alkaline phosphatase activity observed after adding magnesium to plasma from magnesium-deficient rats indicates that the efficiency of the circulating enzyme is reduced by a lowered concentration of magnesium in the plasma. As the enzymatic activity in the plasma of deficient rats was still lower after the addition of magnesium than in the plasma from control rats, it appears that the concentration of the alkaline phosphatase enzymes in the plasma may also be reduced by magnesium deficiency.

### High-sulphur Proteins as a Major Cause of Variation in Sulphur Content between $\alpha$ -Keratins

A common feature of the wide variety of mammalian tissues classified as  $\alpha$ -keratins is that they may be split into two separate protein fractions<sup>1-3</sup> bearing a general resemblance to the 'high-sulphur' and 'low-sulphur' protein-fractions first recognized in wool<sup>4,5</sup>. However, in these  $\alpha$ -keratins which include hair, fur, wool, horn, nail, hoof, quill and baleen, the percentage of sulphur present varies greatly and covers the approximate range 2-6 per cent<sup>6-8</sup> (Table 1). In general the horny keratins contain smaller amounts of sulphur than do the hairs and so the sulphur content of sheep horn, for example, is often lower than the sulphur content of wool from the same animal. It has been suggested<sup>7</sup> that these differences in sulphur content can be used as a means of distinguishing keratins from one another, but in the case of wool it is now well established that there is a characteristic range

of values of sulphur content (about 2.0-4.2 per cent) rather than a particular value for this keratin. A review of the relevant literature is given by Reis and Schinckel<sup>10,11</sup>. A sheep will produce wool with a high sulphur content during high levels of nutrition or during the abomasal infusion of sulphur-containing amino-acids; on the other hand, wool with a much lower sulphur content will be produced when the animal is on a copper-deficient or low-nutritional diet<sup>12-13</sup>. Moreover, these variations in the sulphur content of wool have been shown to originate primarily in the 'high-sulphur' proteins which change both in amount and in sulphur content<sup>1,14-16</sup>.

In recent work, Gillespie and Inglis<sup>8</sup> have shown that, when  $\alpha$ -keratins are compared, they differ greatly both in the amount and in the type of 'high-sulphur' proteins which they contain. These results, when combined with analytical data<sup>9</sup> on the 'low-sulphur' proteins (Table 1), strongly suggest that the main difference between  $\alpha$ -keratin types lies in variations in the 'high-sulphur' group of proteins. The values presented for the proportion of high-sulphur protein in each keratin are underestimates because of the difficulty of measuring the amount of this protein bound to the 'low-sulphur' fraction and removed from it during purification. It is not possible to make a sulphur balance because of the uncertainty about the amount of 'high-sulphur protein' present and because of the uncertainty of the composition of the unextracted residue (10-15 per cent of each keratin).

Table 1. SULPHUR ANALYSES OF S-CARBOXYMETHYL PROTEINS FROM VARIOUS  $\alpha$ -KERATINS

Keratin Type *	Low-sulphur protein			High-sulphur protein		
	% S †	% S ‡	Sulphur contributed to keratin g/100 g	% S †	% S ‡	Sulphur contributed to keratin g/100 g
Raccoon hair	5.6	2.3	1.0	45	7.1	3.2
Monkey hair	5.2	2.3	1.2	39	7.1	2.8
Guinea-pig hair	4.8	2.1	1.2	34	7.2	2.4
Rabbit hair	4.2	2.3	1.4	29	7.2	2.1
Bovine hair	4.0	1.7	1.0	29	5.9	1.7
Wool (sulphur-enriched)	3.8	1.9	1.1	81	5.8	1.8
Wool (control)	3.1	2.1	1.4	23	5.0	1.1
Whale baleen	3.0	2.3	1.8	13	5.8	0.70
Porcupine quill	2.6	1.7	1.2	17	5.9	1.0
Sheep horn	2.2	1.6	1.2	13	5.2	0.62
Rhinoceros horn	1.9	1.4	1.2	7	4.3	0.80

\* Origin and preparation of keratins<sup>8</sup>.

† Sulphur estimation by oxygen flask combustion<sup>14</sup>.

‡ From amino-acid composition, using Spence amino-acid analyser.

§ Preparation of proteins<sup>14,17</sup>.

\* In this computation the relation was used: percentage low-sulphur protein = 100 - (percentage high-sulphur protein + 10); it being assumed that each keratin contained 10 per cent of membranes, scales and nuclear remnants.

Nevertheless it is clear that 'low-sulphur' proteins, although not identical in sulphur content, contribute a fairly constant amount of sulphur to each keratin, whereas there is at least a ten-fold variation in the amount of sulphur contributed by the 'high-sulphur' protein. It is therefore proposed as a general hypothesis that variations in sulphur content between  $\alpha$ -keratins are primarily due to the combined effects of variations in quantity and sulphur content of constituent 'high-sulphur' proteins. This would appear to be applicable to both inter- and intra-species differences.

The implications of this are important, for if all  $\alpha$ -keratins have a common mode of synthesis in which there is a primary synthesis of 'low-sulphur' proteins (as  $\alpha$ -filaments), and at a later stage in development the 'high-sulphur' proteins are produced in a secondary synthesis and are inserted between the filaments as an amorphous matrix<sup>18,20</sup>, then there must be a common regulatory mechanism which decides both the amount and type of 'high-sulphur' protein which is produced by a follicle. Although the nature of this mechanism is unknown, certain factors which influence it are known. Species is important, for it is probable that the hair of some animals (for example, the raccoon) is consistently higher in 'high-sulphur' protein than that of others (for example, the sheep). The end-use of the keratin is

possibly important and the horny keratins may owe their particular physical properties to their richness in filaments and comparative paucity in matrix proteins<sup>8</sup>. Diet is involved, at least in so far as the supply of *S*-amino-acids is concerned, although judging from experiments with sheep its effects are restricted to within certain limits<sup>18</sup>. A study of this control mechanism may provide a valuable insight into the processes by which keratins are formed.

### Interaction of 4-Dimethylaminoazobenzene and Dietary Fat in the Regulation of Hepatic Microsomal Ascorbic Acid Synthesis

An increase in urinary ascorbic acid excretion in rats has been demonstrated to occur after an injection of 4-dimethylaminoazobenzene (DAB) and also after the injection of several methylated derivatives of this carcinogen<sup>1</sup>. Other types of compounds, such as chloretone, aminopyrine, meprobamate and phenylbutazone, also increase the urinary excretion of ascorbic acid in rats<sup>2,3</sup>. It has been suggested that these compounds stimulate the biosynthesis of glucuronic acid as an adaptive response for detoxication processes, and that some of the glucuronic acid is then utilized for the synthesis of ascorbic acid.

Some hepatic microsomal enzymes which metabolize foreign substances have been noted to increase in activity after the administration of several carcinogenic hydrocarbons<sup>4</sup>. In addition, alterations in the swelling properties of hepatic microsomes have been noted after the administration of carcinogenic azo dyes<sup>5</sup>. The induction of hepatomas by azo dyes appears to be influenced by the quantity and type of fat in the diet. Corn oil accentuates the formation of DAB-induced hepatomas, whereas a fat-free diet, or hydrogenated coconut oil, appears to inhibit tumorigenesis<sup>6</sup>. The effects of dietary fatty acids may be mediated via their incorporation into phospholipids. Since phospholipids probably form the structural matrix for RNA and enzyme systems in the microsomes<sup>7</sup>, changes in the fatty acids of these phospholipids might affect the activity of the enzymes, or influence the effects of carcinogenic compounds on the enzymes.

To investigate the combined influence of dietary fat and DAB on hepatic microsomal ascorbic acid synthesis, six groups of three-month-old Sprague-Dawley rats (8 rats/group) were fed synthetic diets consisting of sucrose, casein, cellulose, choline, a salt mixture and a vitamin mixture (containing 2 mg/kg riboflavin but

adequate in all other vitamins), with additions as follows: Group I, no additions (fat free); Group II, fat-free + 0.08 per cent 4-dimethylaminoazobenzene (DAB); Group III, 20 per cent hydrogenated coconut oil (HCNO); Group IV, 20 per cent HCNO + 0.08 per cent DAB; Group V, 20 per cent safflower oil (SFO); Group VI, 20 per cent SFO + 0.08 per cent DAB. After 4 months on the diets the rats were killed by intraperitoneal injection of sodium pentobarbital ('Nembutal'). Livers were excised and homogenized, and the microsomes isolated by ultracentrifugation by the method of Hogeboom<sup>8</sup>. Microsomal L-ascorbic acid synthesis from D-glucuronolactone was investigated *in vitro* using the method of Chatterjee *et al.*<sup>9</sup>. The test system contained 0.25 ml. of the microsomal suspension (equivalent to 250 mg of wet liver tissue), and an additional 2.25 ml. of the following composition and concentration: 0.02 M sodium phosphate buffer (pH 7.4), 0.01 M D-glucuronolactone, and 0.05 M KCN. The mixture was incubated at 37° C for 2 h in air. Ascorbic acid was determined by adding 0.5 ml. 30 per cent metaphosphoric acid to the incubation mixture and titrating against a standard 2,6-dichloroindophenol solution. The microsomal protein content was determined by the method of Gornall *et al.*<sup>11</sup>. The probability (*P*) that apparent differences in the data were due to chance was calculated by the *t* test.

Table 1. MICROGRAMS OF L-ASCORBIC ACID FORMED/MICROGRAM OF PROTEIN

Diet	Without DAB	With DAB
Basic (fat-free)	25 ± 1.3	30 ± 2.1
Basic + HCNO	24 ± 1.3	28 ± 1.9
Basic + SFO	25 ± 0.9	26 ± 2.1

The degree of synthesis of ascorbic acid by hepatic microsome suspensions from rats on the various diets with and without DAB is indicated in Table 1.

Previous investigations have demonstrated that dietary components can affect enzymatic activity<sup>12</sup>. In particular, essential fatty acid deficiency in the rat has been shown to result in alterations in several hepatic enzymes<sup>13,14</sup>. Succinic, glutamic and butyric dehydrogenases were found to be reduced in activity, and cytochrome oxidase and choline oxidase were increased, but there was no change in succinic oxidase activity. In the present work, the amount or type of dietary fat alone appeared to have no effect on the microsomal enzyme system for the synthesis of ascorbic acid, indicating that the maintenance of these enzymes is probably independent of exogenous essential fatty acids.

Some investigations have shown that, in general, in hepatomas there is a deficiency of drug-metabolizing enzymes, such as the azo dye reductase and *N*-demethylase systems<sup>15</sup>. The O3H mouse hepatoma, however, retains the microsomal enzyme that converts L-gulonolactone to L-ascorbic acid<sup>16</sup>. Similarly, in the present investigation, representing a pre-neoplastic stage in DAB carcinogenesis (none of the rats had developed overt tumours), the enzyme system converting D-glucuronolactone → L-gulonolactone → L-ascorbic acid was shown to be intact in microsomes of rats fed DAB with safflower oil. Furthermore, ascorbic acid synthesis was increased above normal in the liver microsomes of rats fed DAB with a fat-free diet, and also increased, although to a lesser extent, in those fed DAB with hydrogenated coconut oil. In a previous investigation by Morin<sup>17</sup>, it was shown that DAB administration resulted in an increased percentage of oleic acid and decreased stearic acid in the choline containing phospholipids (particularly the lecithins) in the hepatic microsomes of rats on a fat-free diet. Similar alterations, although less marked, were produced by feeding DAB with hydrogenated coconut oil, but not with safflower oil. Evidence from several investigations suggests that the mechanism of action of most drugs in increasing enzymatic activity is to increase the amounts of the enzymes via an increased microsomal protein synthesis<sup>18</sup>. Since the increases in ascorbic acid-synthesizing activity

produced by DAB in each dietary group parallel the microsomal phospholipid changes, it may be postulated that a specific substitution of oleic for stearic acid in the lecithins of the microsomal membrane alters the arrangement of the RNA it supports such as to produce increases in the synthesis of specific proteins.

This investigation was supported by a grant from the California Institute for Cancer Research of the U.C.L.A. School of Medicine, and also supported in part by the U.S.P.H.S. general research support grant award to the University of California at Los Angeles.

## Acetylcholine in the Electric Organ of *Torpedo*

Feldberg and Fessard<sup>1</sup> have shown that the electric organ of *Torpedo marmorata* is activated by acetylcholine (ACh) and that it contains a substance like ACh, as determined by bioassay, equivalent to between 40 and 100 µg ACh/g tissue. It has been suggested recently<sup>2,3</sup> that not all the material extracted from nervous tissue and bioassayed as ACh is in fact ACh. Since, so far as we are aware, the ACh-like activity extracted from *Torpedo* is the highest reported for any vertebrate tissue, confirmation of the nature of the active substance and a study of its metabolism in the electric organ are of interest. As a necessary preliminary we have reinvestigated the content of ACh by three different extraction procedures.

In our first experiments the tissue was extracted with acid-ethanol according to Crossland<sup>4</sup>. In subsequent experiments this method was compared with the usual trichloroacetic acid (10 per cent, w/v) procedure and with a perchloric acid extraction technique developed in this laboratory<sup>5</sup>. Samples of tissue (1 g or less) were minced with scissors in two volumes of 0.2 N perchloric acid and then rapidly and thoroughly homogenized in "Teflon"-glass hand-operated homogenizers. The suspensions were centrifuged, the supernatants stored at 4° C and the precipitates re-homogenized three times with two volumes of water and recentrifuged. The supernatants were combined and brought up to pH 4 with 0.2 N sodium hydroxide. The extracts, in a final dilution of 1 in 100, were assayed against acetylcholine chloride on the frog rectus abdominis muscle, guinea-pig ileum and the dorsal muscle of the leech; the activity was the same on all three test objects. Alkali-boiled controls were used in all assays. The average values from two series of experiments in which perchloric acid and acid-ethanol were used, and where perchloric acid and trichloroacetic acid were compared, are shown in Table 1. These results were from extractions performed at 0°-

10° C. The yields were lower when the tissue was initially frozen with liquid nitrogen, an observation in agreement with Hobbiger and Werner<sup>6</sup>. The very low activities obtained with acid-ethanol can be attributed to the failure of the extractant to inactivate the tissue cholinesterase completely. If the minced tissue was left in contact with eserine (10<sup>-4</sup> M) or diisopropylphosphorofluoridate (10<sup>-4</sup> M) at 0° C for 30 min or longer before extraction with acid-ethanol the ACh-levels were comparable with those obtained using perchloric acid. The range of activities obtained with perchloric acid was between 65 and 130 µg ACh/g tissue, suggesting that the values reported by Feldberg and Fessard<sup>1</sup> may be on average too low rather than too high. Since one of the objects of the investigation was to characterize chemically the active substance which by bioassay appears to be ACh, perchloric acid extraction seems to be the method of choice. Trichloroacetic acid has the disadvantage that the procedure is more time consuming. Moreover, it does not precipitate phospholipids so effectively<sup>7</sup> and may interfere with the chromatography of ACh<sup>8</sup>. Results of the chemical investigation will be published separately.

Table 1. COMPARISON OF METHODS OF EXTRACTION OF ACETYLCHOLINE FROM THE ELECTRIC ORGAN OF *Torpedo*

	ACh content (µg/g tissue)		
	perchloric acid	acid-ethanol	trichloroacetic acid
Series 1	86	25	—
Series 2	70	—	68

We have some evidence that endogenous synthesis of ACh may occur both in the excised whole organ and in minced tissue. Samples of tissue allowed to remain at room temperature for periods of up to 2 h contained more ACh activity than those extracted immediately the fish was killed. The largest increase was equivalent to 60 µg ACh/g tissue in a sample left for 1 h at room temperature. No increase in ACh activity was found in samples stored at 0° C. *In vitro* estimation of choline acetyltransferase activity in cysteine-sucrose tissue homogenates showed that the enzyme was capable of a rate of ACh synthesis of 5-8 mg ACh/g tissue/h.

These experiments largely confirm the original observations of Feldberg and Fessard<sup>1</sup>. In addition a new and convenient method of extraction has been developed which forms a basis for further study of the metabolism of ACh in the electric organ of *Torpedo*.

## Red Pigments of *Dactynotus rudbeckiae* and *D. ambrosiae* [Homoptera, Aphididae]

THE extensive investigations of Lord Todd and his colleagues<sup>1</sup> have shown that several related perylene-quinone pigments, the erythroaphins (Fig. 1), can be obtained from many aphid species; the two most completely investigated representatives, the erythroaphins *fb* and *af*, are stereoisomers of the formula C<sub>22</sub>H<sub>12</sub>O<sub>6</sub>. These pigments, however, are not present in the live insect, but are formed through post-mortem enzymatic transformations of yellow precursors, the protoaphins, which do not contain the perylene nucleus<sup>2a</sup>. In the course of research on naturally

occurring perylenequinones<sup>8</sup>, we have investigated the pigments of two bright red species of the aphid genus *Dactynotus*, since it seemed possible that their colour might be due to preformed perylenequinones. Earlier, Todd *et al.*<sup>9</sup> had observed the occurrence of very small amounts of aphid pigments in *D. jaceas*; *D. cirsii*, however, was found to contain instead a red pigment which has not been described in detail but which, from its uncharacteristic absorption spectrum, is not a perylenequinone.

We have now found that the striking red colour of *D. rudbeckiae* (Fitch) and *D. ambrosiae* (Thomas) is likewise due to pigments which do not contain the chromophore of the erythroaphins. We have isolated the main pigment of *D. rudbeckiae* in pure, crystalline form; two very minor constituents of the pigment mixture were likewise obtained crystalline, although not yet quite pure. We propose the name rhododactynaphins *A*, *B*, and *C* for these substances (see 'Addendum'). They do not seem to be identical with the pigments of *D. cirsii*; nor are they anthocyanins, as has been claimed<sup>4</sup> on the basis of a very cursory examination of *D. rudbeckiae* (syn. *Tritogenaphis rudbeckiae*).

For the isolation of the rhododactynaphins, *D. rudbeckiae* was collected locally from *Rudbeckia laciniata*; the aphids were killed by brief exposure to dry-ice temperature, removed from the stalks of the plant, and triturated with acetone. The red, benzene-soluble portion of the deep-brown acetone extracts was chromatographed on a column of silica-gel *H* deactivated with 5 per cent water. Washing with benzene removed the  $\beta$ -carotene present<sup>4</sup>, together with a large amount of fat (or wax). Rhododactynaphin *A* was next eluted with 2 per cent methanol in chloroform; yield, ~0.2–0.4 per cent of the fresh weight of the aphids. It was followed closely by pigment *B*, while pigment *C* was eluted by methanol/chloroform 1:3. Recrystallization of rhododactynaphin *A* from benzene removed small amounts of a colourless contaminant with strong blue ultra-violet fluorescence, yielding the pure pigment. Comparison, by thin-layer chromatography, of the benzene-soluble part of acetone extracts of *D. rudbeckiae* and *D. ambrosiae* showed that the latter species likewise contains  $\beta$ -carotene and the three rhododactynaphins.

Since neither species of aphid is common, only very limited amounts of these pigments have been available thus far. They have enabled us to make the following observations, which may serve to characterize the compounds: pure rhododactynaphin *A* forms glistening deep-red platelets or scarlet needles. On heating, it gradually decomposes above about 240°. It is homogeneous on thin-layer chromatograms (silica-gel *H*, 2 per cent methanol in chloroform). Rhododactynaphin *A* is insoluble in water and hexane, more or less soluble in the common organic solvents, especially readily in acetone. The solutions are bluish-red. It is not extracted into concentrated aqueous hydrochloric acid from its solution in benzene, thus differing from the pigment of *D. cirsii*, which is extracted<sup>9</sup> from its hexane solutions. Concentrated sulphuric acid gives a crimson solution; the pigment dissolves with stable, yellowish-green colour in acetic anhydride containing one drop of concentrated sulphuric acid. The alcoholic solution of rhododactynaphin *A* turns greenish-brown with ferric chloride, purple with magnesium acetate. Aqueous or alcoholic alkali produces an emerald-green colour which changes to yellow within 1–2 seconds; afterwards, a purplish-red colour develops. These colour changes are reminiscent of those given by the mould pigment purpogenone<sup>8</sup>. Aqueous ammonia or sodium carbonate produces similar effects. The red colour of solutions in aqueous alkali or carbonate fades on further standing; that in ammonia is stable, and acidification and extraction with benzene yield a crystalline purple pigment with a characteristic four-banded absorption spectrum. The red solution of rhododactynaphin *A* in sodium carbonate is reversibly changed to yellow by sodium hydrosulphite; the resulting product is not fluorescent. Reductive acetylation of rhododactynaphin *A* gave a colourless, crystalline product.

The visible spectrum of rhododactynaphin *A* shows one band, without fine-structure;  $\lambda_{\max}$  500 m $\mu$ . IR (KBr disk):  $\nu(\text{CO})$  1,633, 1,610  $\text{cm}^{-1}$ ; other bands: 3,400, 2,910, 2,840, 1,440, 1,400, 1,280  $\text{cm}^{-1}$ , etc.

Mass-spectrometry, carried out by Mr. D. W. Thomas in Prof. Biemann's laboratory at the Massachusetts Institute of Technology, indicated a molecular weight of 274, and loss of  $\text{CH}_3$ ,  $\text{C}_2\text{H}_5$ ,  $\text{CH}_3\text{CO}$ , and  $\text{CO}$ . High-resolution mass-spectrometry, due to Dr. R. J. Highest (National Heart Institute), showed that 274 corresponds to  $\text{C}_{18}\text{H}_{14}\text{O}_8$ . However, osmometric determination gave a value of 548, making it appear very probable that rhododactynaphin *A* is a  $\text{C}_{56}$  compound, a finding which suggests that it may be related to the pigments of the aphid series. This hypothesis is further supported by the presence, in the NMR spectrum of the pigment, of a quartet centred at  $\delta \approx 1.65$  p.p.m. [ $\delta(\text{TMS}) = 0$ ] which is quite similar, in shape and location, to quartets occurring in the spectra of erythroaphin *al*<sup>4</sup> and of such related compounds<sup>10</sup> as isoeleutherin and the naphthoquinones formed on reductive cleavage of the protoaphins *fb* and *sl*. This quartet is produced by the two methyl groups of the dihydropyran ring present in these compounds. The NMR spectrum, and the mass-spectrometric cleavage into a  $\text{C}_{18}\text{H}_{14}\text{O}_8$  fragment representing (not necessarily precisely) one half of the molecule, could be interpreted on the assumption that rhododactynaphin *A* is a quinone containing at least one component with a carbon skeleton related to those present in the protoaphins. The dihydropyran ring of this component may resemble that of isoeleutherin (Fig. 1) ( $\text{CH}_3$  at position 12) rather than that of the protoaphins ( $\text{CHOH}$  at 12), since the NMR spectrum of rhododactynaphin *A* contains a group of weak bands at  $\delta \approx 2.3$  p.p.m. which is similar to the multiplet caused by the methylene protons in the spectrum of isoeleutherin<sup>11</sup>.

Those properties (spectra, etc.) of rhododactynaphins *B* and *C* which could be examined with the available trace amounts are very similar to those of *A*.

Evaporation of the benzene extracts from column chromatography gave a crystalline fat; the free fatty acids obtained from it, and their methyl esters, were likewise crystallized. Gas-chromatographic investigation of the latter, essentially as described by Barlow<sup>12</sup>, showed that the preponderant fatty acid of this species is myristic acid, in agreement with the findings<sup>7,8</sup> on other aphids. In addition, small amounts of lauric and palmitic acids and of unsaturated  $\text{C}_{18}$ ,  $\text{C}_{14}$ , and  $\text{C}_{12}$  acids were present.

It is hoped to continue the investigation of the rhododactynaphins when additional material becomes available.

We thank Dr. Harvey Souder for suggesting this investigation, Dr. Louise M. Russell for the taxonomic identification of the aphids, and Dr. Norman E. Sharpless for the gas-chromatographic study of the fatty acids. Part of the work was carried out in the Chemistry Department of Gettysburg College, Pennsylvania.

Fig. 1

**Addendum.** After completion of this manuscript, we learned from Lord Todd that Dr. D. W. Cameron and associates in his laboratory have for some time been engaged in a detailed study of the pigments from such aphid species as *D. citri* and *D. jaceae*. Our preliminary findings on the pigments of the two American species appear to agree well with the more advanced ones on *D. jaceae* made at Cambridge. Lord Todd has also informed us that the generic name 'daetynaphin' will be proposed for the pigments of *Dactynotus* spp., and has suggested the name 'rhododaetynaphin' for the pigments isolated by us. This suggestion has been adopted in the foregoing account.

### Actomyosin and Myosin of Vascular Smooth Muscle

VARIOUS procedures have been used for extracting contractile protein from vascular smooth muscle<sup>1-3</sup>. In the course of preparing extracts from the cow carotid artery using a medium of 0.6 M KCl, the actomyosin content was estimated by measuring the ATP-sensitivity and viscosity number ( $Z_\eta$ ). In this report it will be shown that the extract from cow carotid artery consists of actomyosin and an actin-combining component, probably myosin, firmly associated with one another. It is believed that this firm association is a manifestation of unusual solubility properties of vascular smooth muscle myosin.

Extracts containing contractile protein from cow carotid artery were prepared as follows: 50 g artery were stripped of adventitia and minced, and three volumes of Weber-Eddsall solution and 0.5 ml.  $5 \times 10^{-3}$  M ATP at pH 7.0 were added. The mixture was homogenized in a Waring blender in the cold for 30 sec, shaken for 18 h at 4° C, and centrifuged. The supernatant was collected and diluted 14-fold with ice-cold water. After standing for several hours at 4° C, a precipitate formed which was collected and redissolved in 0.6 M KCl, and then reprecipitated by dilution as before. This precipitation was repeated for 6 cycles. The final yield was generally 15–20 mg of contractile protein which showed ATP-ase activity, ATP-induced syneresis, and a viscosity in 0.6 M KCl which was reversibly lowered by the addition of ATP. ATP-ase assays and syneresis tests were carried out using the protein in a solution containing 0.05 M KCl, 0.02 M imidazole buffer pH 7.2, 0.005 M of either  $\text{CaCl}_2$  or  $\text{MgCl}_2$ , and 0.0025 M ATP (Disodium, Pabst). The method of Fiske and Subba Row was used for measuring inorganic phosphate<sup>4</sup>. Protein was measured using the Lowry method<sup>5</sup>. Viscosity determinations were made at 25° C using an Ostwald viscometer containing the contractile protein dissolved in 3.0 ml. of a solution of 0.6 M KCl, 0.1 M *tris*, pH 7.2. The final concentration of ATP, when added, was  $1.67 \times 10^{-3}$  M. The rabbit skeletal muscle proteins, myosin A, F-actin, and actomyosin, were prepared according to the procedures outlined by Mommaerts<sup>6</sup>.

According to Szent-Györgyi<sup>7</sup>, the addition of one part actin to a solution containing 4–5 parts of myosin gives a viscosity drop, when ATP is added, which corresponds

to a change in the logarithm of the relative viscosity of 0.28 per 2.2 mg protein/ml. Needham and Williams<sup>8</sup> showed that 1 mg uterus actomyosin/ml. gives a change in the logarithm of the relative viscosity of 0.10–0.11. In our experiments, in order to estimate the amount of actomyosin in the extracts, we have assumed that a drop of 0.1 of the logarithm of the relative viscosity corresponds to 1 mg actomyosin/ml. The average actomyosin content in 12 extracts was found to be 27 per cent, the range being 19.4–37.5 per cent. In addition, it was found that a significant amount of the protein in the extract reacted with skeletal muscle F-actin to give an increase in viscosity which could then be lowered by the addition of ATP (Tables 1 and 2). The addition of actin caused the  $\Delta \log \eta_{rel}$  per mg protein per ml. to rise from 0.04 to 0.14 (Table 1). This value of 0.14 shows good agreement with values obtained using actomyosin from skeletal and uterine muscles<sup>7,8</sup>.

The data in Tables 1 and 2 indicate the presence of a myosin-like component. From these data it has been estimated that the composition of protein in the artery extract is roughly 1/4 actomyosin and 3/4 myosin or an actin-combining component. When the artery extract was dissolved in 0.6 M KCl and precipitated at 0.28 M KCl, pH 6.7, the resulting precipitate still reacted with added F-actin. When the artery extract was brought to 32 per cent ammonium sulphate saturation at pH 7.0, the resulting precipitate still reacted with F-actin. Both these methods are accepted procedures for separating skeletal myosin from actomyosin<sup>9</sup>.

Thus, because the actin-combining component is not readily separated from the actomyosin, it is possible that the solubility characteristics of myosin from cow artery smooth muscle differ from those of skeletal muscle myosin. Indeed, Hamoir and Laszt<sup>10</sup> observed that skeletal muscle myosin and the 47–60 per cent ammonium sulphate fraction of cow carotid artery, which they believed to be myosin-like, had different properties such as extractability at low ionic strengths, salting out ranges, amino-acid composition, net charge at neutral pH, and thermostability. Also, it is pertinent to note that smooth muscle

Table 1. EFFECT OF F-ACTIN ON THE ATP-INDUCED LOWERING OF VISCOSITY OF CONTRACTILE PROTEIN FROM BOVINE CAROTID ARTERY

Experiment 1*				Experiment 2*			
$\Delta \log \eta_{rel}^\dagger$		$\Delta \log \eta_{rel}/\text{mg total protein/ml.}$		$\Delta \log \eta_{rel}^\dagger$		$\Delta \log \eta_{rel}/\text{mg total protein/ml.}$	
Before actin	After actin	Before actin	After actin	Before actin	After actin	Before actin	After actin
0.5103	0.7960	0.06	0.14	0.2706	0.8009	0.04	0.14

\* The total protein, after the addition of F-actin which was 1/4 that of the contractile protein, was 5.8 and 6.1 mg/ml. for Experiments 1 and 2, respectively.

$^\dagger \Delta \log \eta_{rel}$  = the lowering of the logarithm of the relative viscosity induced by the addition of ATP.

Table 2. EFFECT OF F-ACTIN ON THE VISCOSITY NUMBER AND ATP-SENSITIVITY OF CONTRACTILE PROTEIN FROM BOVINE CAROTID ARTERY

Date	Preparation	$Z_\eta^*$		ATP-sensitivity $^\dagger$		Protein conc. mg/ml.
		Before actin	After actin	Before actin	After actin	
6/8	Artery protein	0.15	0.23	23	103	7.3
6/4	"	0.16	0.21	25	98	8.6
6/9	"	0.23	0.30	33	117	4.3
6/17	"	0.23	0.35	51	171	8.6
6/19	"	0.20	0.32	40	109	9.4
6/20	"	0.23	0.30	46	111	7.6
7/9†	"	0.19	0.40	57.5	121	5.8
7/10†	"	0.27	0.44	77.5	143	—
—	Actomyosin from rabbit skeletal muscle	0.46	—	124	—	4.0
—	Myosin from rabbit skeletal muscle	0.16	0.56	0	150	5.3

The preparation of the artery contractile protein is described in the text. F-actin when added was 1/4 that of the artery protein.

\*  $Z_\eta = 2.3 \log \eta_{rel}/\text{protein conc. (mg/ml.)}$ .

$\log \eta_{rel}$  = logarithm of the relative viscosity.

$^\dagger$  ATP-sensitivity in per cent =  $\frac{\log \eta_{rel} - \log \eta_{rel}^{\text{ATP}}}{\log \eta_{rel}^{\text{ATP}}} \times 100$

$^\dagger$  In addition to being reprecipitated and redissolved for 6 cycles, the contractile protein was dissolved in 0.6 M KCl, brought to 0.28 M KCl pH 6.8 and centrifuged for 30 min at 10,000 r.p.m.

myosin as prepared by other workers is not extracted directly from the muscle but rather is made by ATP dissociation of previously prepared actomyosin<sup>2,10</sup>.

Consideration was given to the possibility that the high levels of *F*-actin used were giving the same anomalous viscosity effects on artery actomyosin which have been observed for skeletal muscle actomyosin<sup>7</sup>. This, however, does not appear to be the case. The artery protein did not show the anomalous viscosity behaviour even when a large excess of skeletal muscle *F*-actin was added.

A different preparation of artery actomyosin, prepared according to the procedure of Laszt and Hamoir<sup>1</sup>, did not have the actin-combining moiety associated with it. The data (Table 3) show that even large amounts of *F*-actin failed to induce an elevated  $Z_{\eta}$  or ATP sensitivity when added to actomyosin prepared by the method of Laszt and Hamoir<sup>1</sup>.

Table 3. EFFECT OF *F*-ACTIN ON THE RELATIVE VISCOSITY OF ARTERY ACTOMYOSIN\*

<i>F</i> -actin/AM	Preparation 1 $Z_{\eta}$ ATP sensitivity (%)	Preparation 2 $Z_{\eta}$ ATP sensitivity (%)
No actin	0.25 36	0.18 27
1/20	0.33 35	0.11 32
1/10	0.29 45	0.13 40
1/5	0.37 39	0.26 72

\* The two preparations of artery actomyosin were made according to the method of Laszt and Hamoir<sup>1</sup>.

Viscometry conditions were as described in the text. The *F*-actin was from rabbit skeletal muscle. The *F*-actin/actomyosin was on a weight basis (mg protein). The concentrations of actomyosin in the viscometer were 1.5 mg/ml and 1.8 mg/ml for preparations 1 and 2, respectively.

The results of this study indicate that a firm association exists between cow carotid artery actomyosin and a myosin-like component. Since the association exists even after treatment to remove myosin it is suggested that artery myosin is different in solubility properties from skeletal muscle myosin.

This work was supported in part by research grants from the National Heart Institute (HE-07353 and HE-06315), U.S. Public Health Service, and by the Heart Association of South-western Ohio.

### Further Purification of Chick Interferon

CHICK allantoic fluid interferon has been purified to various extents by several groups of workers. Among those who prepared interferon of high specific activity, Lampeon *et al.*<sup>1</sup> achieved a purification factor of 1830 after treatment with perchloric acid, concentration with zinc acetate and two fractionations on 'OM-cellulose'. Such material still contained an inactive protein component that was only removed by electrophoresis on 'Pevikon'. The final material had been purified 4,500 times. Fantes *et al.*<sup>2</sup> purified interferon several thousand times by adsorption on 'Dowcil', elution with KSCN, precipitation of impurities in the presence of KSCN at pH 3.5, precipitation of interferon with methanol at pH 7.5 and chromatography on DEAE cellulose at pH 7.5. Merigan<sup>3</sup> purified crude interferon with perchloric acid and zinc acetate by the method of Lampeon *et al.*<sup>1</sup>, achieving a 15-fold purification. Such material, after one chromatographic fractionation on 'OM-Sephadex', using a pH gradient instead of Lampeon's stepwise process for eluting

the active ingredient, was claimed to be purer than Lampeon's material, though no evidence of electrophoretic homogeneity was presented.

We have slightly modified our original method<sup>2</sup>. Instead of neutralizing the acid KSCN supernatant fluid before precipitating with methanol, we lowered the pH further to 2.0 and added methanol (5 vol.) at this stage, precipitating some more inactive protein. The pH of the methanolic supernatant fluid was then adjusted to an apparent value of 7.5, causing precipitation of the active material. Chromatography on DEAE-cellulose was carried out as described before<sup>2</sup>. The interferon, when chromatographed on DEAE cellulose, became re-diluted and was reconcentrated on 'OM-Sephadex'. Adsorption was performed at pH 5.5 in 0.1 M phosphate buffer, with subsequent washing with 0.1 M phosphate buffer at pH 6 until the eluates contained no more than about 2 µg/ml. protein, as determined by the method of Lowry *et al.*<sup>4</sup>. Elution was carried out with a 0.1 M phosphate buffer gradient of rising pH.

Three such preparations were subjected to disc electrophoresis in acrylamide gel columns by Dr. J. Williams (personal communication) at the Laboratory of Molecular Biology in Cambridge. Two of the samples, after staining with amido schwarz, exhibited only one protein band. Dissection and assay of two control columns showed that the biological activity resided in those bands. The third sample contained some minor protein contaminants, estimated to amount to less than 5 per cent of the total.

The purity of the most potent DEAE-eluate fractions was sometimes of the same order as that of the post 'OM-Sephadex' fractions, but the 'OM-Sephadex' process enabled the less pure off-peak DEAE cellulose fractions to be purified to the same extent, thus increasing the overall yield of highly purified material.

The post-DEAE material—a mixture of highly and moderately purified fractions—applied to 'OM-Sephadex' had usually been purified about 500-fold. When, on the other hand, pre-DEAE material (purified about 80 times on average) was fractionated on 'OM-Sephadex' in a similar way, it was not found possible to free the active material from an inert protein with an elution peak at a pH only just above that of interferon.

The best fractions were purified well over 10,000 times and contained about one million interferon units per mg protein. As the specific activities of crude interferons and also assay methods vary from one laboratory to another, these figures do not necessarily mean that interferon prepared by the process described here was of a higher degree of purity than that obtained by other workers.

The iso-electric point of partly purified interferon was determined electrophoretically in a sucrose gradient by Dr. A. Polson (personal communication) at the University of Cape Town and found to be about pH 6.8-6.9.

Purified interferon was, as mentioned in our previous publication<sup>2</sup>, highly species specific. This has since also been reported by Merigan<sup>3</sup> and Baron *et al.*<sup>5</sup>. Contrary to the claims of a patent for 'non-specific interferon', we were unable to overcome the species specificity of crude or purified chick interferon by treatment with carboxypeptidase.

I thank Mr. C. F. O'Neill for his assistance and Mr. P. J. Mason for carrying out the interferon assays.

## PHYSIOLOGY

Stimulation by Aldosterone of Active Sodium Transport by the Isolated Colon of the Toad, *Bufo marinus*

DESPITE the large volume and sodium concentration of digestive secretions, the losses of sodium incurred with faeces are negligible in normal circumstances<sup>1,2</sup>. Return to the organism of sodium present in the intestinal lumen depends in all likelihood on active transport process(es); in the case of the toad colon, this had been established by Ussing and Andersen<sup>3</sup>, who showed that sodium moves from the mucosal to the serosal surface in the absence of electrochemical potential gradient; furthermore, this movement was expressed quantitatively by the current required to annihilate the electrical potential difference which can be recorded across the membrane.

It has been reported previously that aldosterone is a physiological hormone for the toad, *Bufo marinus*, and that its concentration in plasma increased when the animals were transferred from a habitat rich in sodium to distilled water<sup>4,5</sup>. This transfer resulted in augmented active sodium transport by their ventral skin and urinary bladder. Injection of aldosterone into the toads or incubation in the presence of the hormone also brought about a stimulation of sodium transport activity by bladder<sup>4,6</sup> and skin<sup>7</sup>.

The influence of aldosterone on active sodium transport by the toad colon was examined because, in mammals, the adrenal cortical secretion, especially aldosterone, has been shown to exert an influence on faecal sodium<sup>8,9,10</sup>.

After pithing the toad, the colon was opened longitudinally and gently cleaned. Suitable unstripped fragments were mounted as diaphragms between conical 'Lucite' chambers (inner diameter of 16 or 20 mm according to the size of the tissue pieces), both surfaces being bathed at room temperature in aerated Ringer's fluid the composition of which was (in mM/l.), Na, 117.5; K, 2.0; Ca, 1.0; HCO<sub>3</sub>, 2.5; Cl, 119.0; osmolality, 0.225. The membranes were incubated according to the method devised by Ussing and Zerahn<sup>11</sup>; they were maintained short-circuited with interruptions at 10- to 15-min intervals for transmembrane potential readings. One hour of incubation was allowed before the results were considered meaningful.

In the first series of experiments, colons were used of toads kept for a few days in shallow water or in 50 per cent diluted Ringer's solution. An additional group of toads maintained in water received subcutaneously 10 µg *d*-aldosterone dissolved in 0.25 ml. Ringer's, the evening preceding the incubation. As shown in Table 1, the short-circuit current, averaged for the second hour of incubation, was one and a half times as high for the colon of toads kept in water as for that of toads kept in Ringer's. This increased activity was ascribed to the elevated aldosteronaemia in toads of the former group<sup>4</sup> since treatment of the animals with aldosterone resulted in a further increase in sodium transport (Table 1). The transmembrane potential rose more markedly than the short-circuit current, for an unknown reason.

As a next step, in ten instances, the colon of toads maintained in Ringer was divided in two, both pieces being incubated simultaneously as described. After 1 h, enough *d*-aldosterone was introduced on the serosal side of one piece of each pair to achieve a final concentration of 10<sup>-6</sup> M, and incubation was allowed to proceed further for 3 h. During the 30-min period which followed addition of the steroid hormone, the mean short-circuit current was (in µamp/2 cm<sup>2</sup>) 41.8 ± 4.2 (*S.E.*); it started to increase, after about 90 min, reaching 46.0 ± 5.5 over the last 30-min period. The corresponding values for the matched, untreated fragments decreased instead, from 40.0 ± 5.1 at the beginning to 30.9 ± 2.8 at the end of the 3-h experimental period.

Table 1. EFFECTS OF HABITAT AND OF ALDOSTERONE ON ACTIVE SODIUM TRANSPORT BY TOAD COLON (MEAN ± *S.E.M.*)

		Short-circuit current (µamp/cm <sup>2</sup> )	Potential difference (mV)
Toads maintained in saline	(20)*	21.5 ± 1.4	58 ± 0.3
Toads maintained in water	(20)*	32.8 ± 1.9	107 ± 0.4
Toads injected with aldosterone	(15)*	42.1 ± 3.0	28.6 ± 1.2

\* No. of animals per group.

Table 2. REPRODUCTIONS ON SHORT-CIRCUIT CURRENT AND SODIUM MOVEMENT OF DILUTION OF SODIUM PRESENT ON THE MUCOAL SIDE OF TOAD COLON

Exp. No.	Sodium concentration on mucosal side (in mM/L)	Short-circuit current, after dilution of sodium on mucosal side* (in % of reference value)	Sodium flux (in µequiv./h) computed from short-circuit current	Sodium flux (in µequiv./h) computed from isotopic flux	(2)/(1) × 100 (%)
10	7.1	55	0.906	0.784	87
5	7.3	70	0.397	0.520	133
9	9.5	63	2.611	2.374	91
13	9.9	74	2.945	2.332	79
11	10.4	76	1.511	1.563	106
3	16.0	82	1.056	1.204	114
1	16.3	74	0.708	0.764	108
19	24.7	86	2.229	2.202	99
8	27.0	70	1.677	2.234	133
4	40.2	90	0.659	1.228	186

\* The current averaged 53.0 µamp immediately before dilution, and 51.7 µamp after replacement of the diluted solution with unmodified Ringer's.

The influence of aldosterone was analysed as was done for studies with the toad bladder<sup>12</sup>, that is, the change of membrane activity occurring in the absence of treatment during the period of time considered (−9.1 µamp as a mean, in the present case) was subtracted from the change noted when the matched membrane was exposed to aldosterone (+3.2 µamp as a mean, in the present case). Stimulation of short-circuit current exerted by aldosterone on the toad colon thus averaged 13.3 µamp ± 5.3 (*S.E.* mean difference) (*P* < 0.05).

These results on the responsiveness of the colon of the toad to aldosterone, endogenous and exogenous, *in vivo* and *in vitro*, are similar in quality and amplitude to previous results obtained with toad skin and bladder. The significance of the resemblance is enhanced, it seems to us, by the fact that also in the case of the toad colon the sodium transport capacity is relatively independent of sodium concentration in the outside bathing solution. This was investigated as follows: after 2 h of incubation of the colon in unmodified Ringer's, the solution on the mucosal side was diluted to a variable extent with a solution in which Mg<sup>2+</sup> replaced Na<sup>+</sup>, sufficient sucrose being added to bring osmolality back to 0.225. The concentration of sodium in this modified solution was checked by flame photometry. Furthermore, 2 µc. <sup>22</sup>Na were introduced on the same side; sampling for measurement of radioactivity flux was performed during the ensuing second and third 30-min periods. The short-circuit current during exposure to this modified Ringer's was expressed relative to the baseline value.

The results of 10 such incubations are presented in Table 2. The short-circuit current decreased only slightly unless mucosal sodium concentration was markedly reduced. Current remained a valid reflexion of net sodium transport despite the asymmetry of the system since a parallelism between mucosa-to-serosa sodium flux and short-circuit current was found in these experimental conditions; the isotopic flux exceeded the flux computed from current by 13.5 per cent ± 9.8 (*S.E.*) (*P* > 0.2).

The reaction of the toad colon exposed on its mucosal side to dilute sodium solutions is thus reminiscent of what is observed with the frog skin<sup>13</sup> and toad bladder<sup>14</sup>; for both preparations, a limited, saturable permeability for sodium of the outer cell membrane(s) seems to represent an important regulating factor of their sodium transport activity. In the case of the toad bladder, there are arguments pointing at aldosterone stimulating active sodium transport by increasing the permeability at the outer cell

membrane(s) rather than by direct action on the sodium 'pump'<sup>12</sup>.

It is therefore possible that only those membranes which allow sodium in on account of a process complying with saturation kinetics are capable of response to aldosterone which would somehow weaken this diffusion barrier.

Part of this work was carried out with the financial support of the Fonds de la Recherche Scientifique Médicale, Belgium (grant 555). Animals were supplied by Mr. D. R. Fischer, Warner Laboratories, Rio de Janeiro, Brazil, assisted in the shipment by the Ministry of Foreign Affairs of Belgium. Aldosterone was a gift of OIBA, Brussels.

### Adenosine Triphosphate and Muscular Contraction and Relaxation

THERE are three observations which suggest that diminution of the adenosine triphosphate (ATP) content of muscle leads to contraction: (a) the ATP and creatine phosphate (CP) content of isolated striated muscle is about 5 times that of smooth muscle<sup>1</sup>, and the latter always shows a state of partial contraction or tonus; (b) diminution of the ATP content of smooth muscle leads to contraction, and increase to relaxation<sup>2</sup>; (c) adrenaline, which causes relaxation of smooth muscle, increases the ATP content of muscle by about 70 per cent in the first 15 sec<sup>3</sup>.

It may be argued that the contraction of muscle when its ATP content diminishes is not physiological, but is some sort of rigor; the action of adrenaline, however, and the presence of tone, suggests that increase in the ATP content of the muscle leads to a physiological relaxation, and decrease in the ATP content to a physiological contraction. It is therefore tempting to assume that the normal contraction of muscle is due to sudden diminution of its ATP content.

It may be assumed that the primary event in muscular contraction is the breakdown of ATP. The protein-ATP complex in relaxed muscle breaks down into protein-ADP complex and phosphate, resulting in the contraction of muscle and release of energy. The energy which is released by the breakdown of ATP may be considered as a waste in the first instance for the purpose of contraction. It may be assumed that this energy is stored in some way and is utilized later to regenerate the lost ATP and CP; the energy may be stored by raising the energy level of some organic or inorganic ion such as magnesium. Sodium and potassium are not important for contraction, as shown by the fact that when frog stomach muscle is

frequently washed with half isotonic (0.112 M) solution of sucrose, it loses all its sodium in 1 h (ref. 4), and retains only 50 per cent of its potassium (30–35 mM/kg of wet muscle)<sup>5</sup>, but continues to contract spontaneously for about 24 h. Frog heart, when perfused with half-isotonic solution of sucrose, loses all sodium in 1 h and retains only 22 per cent of its potassium (16 mM/kg)<sup>6</sup>, but continues to contract spontaneously for 2–7 h<sup>7</sup>. The foregoing hypothesis reconciles the findings that the heat production in muscle precedes contraction<sup>8</sup> with the view that relaxation of muscle is active<sup>9,10</sup>.

It has been proposed that adrenaline causes relaxation of smooth muscle by producing lactic acid<sup>11</sup>. As adrenaline causes increase in oxygen consumption<sup>12</sup>, the lactic acid production is probably a manifestation of increased metabolism and not the cause of relaxation. It is very likely that adrenaline causes relaxation by increasing the ATP content of smooth muscle.

### Inhibition of Aortic Calcification by means of Pyrophosphate and Polyphosphates

SOME years ago we showed that inorganic pyrophosphate and other longer-chain condensed phosphates could inhibit calcium phosphate precipitation *in vitro* at concentrations as low as 10<sup>-4</sup> M (ref. 1). Later we found that pyrophosphate is a normal constituent of both urine<sup>2</sup> and plasma<sup>3</sup>, and we suggested that it might therefore be important *in vivo* in preventing collagen and other nucleating substances from calcifying<sup>4,5</sup>; calcification would then proceed only after the inhibitor had been destroyed by pyrophosphatase, an enzyme present in high concentrations at mineralizing sites<sup>6,7</sup>. Indirect support for the inhibitory role of pyrophosphate *in vivo* has emerged from studies on urolithiasis. Patients with renal stones excrete less pyrophosphate than normal<sup>8,9</sup> and the excretion of pyrophosphate can be raised by feeding orthophosphate<sup>10</sup>, a procedure claimed to prevent stone formation<sup>11</sup>.

We have tried to gain more direct evidence that condensed phosphates can inhibit calcification *in vivo*. As our test system we have used the calcification of the aorta in rats treated with large doses of vitamin D. Rats were given daily doses of 75,000 units/kg vitamin D<sub>3</sub> orally for 5 days, an amount known to induce heterotopic calcification<sup>12</sup>. When the animals were killed 13 days after beginning the treatment, the aorta was nearly always heavily calcified.

When we gave subcutaneous injections of pyrophosphate or Graham salt (a long-chain polyphosphate,  $n \approx 20$ ) to groups of similarly treated animals from the day before the first dose of vitamin D<sub>3</sub> until they were killed, the calcification was, with the exception of the 160-g group receiving 1 mg phosphorus/kg of Graham salt, either reduced or completely prevented. Equivalent doses of orthophosphate were ineffective. The results of the calcium analysis expressed in mM calcium/g dry wt. of aorta are shown in Fig. 1. Histological analysis of the calcification using silver nitrate correlated well with the

PHARMACOLOGY

Blood Levels of Drug at the Equilibrium State after Multiple Dosing

THERE is ample evidence<sup>1-3</sup> that when a fixed dose of drug is administered in a fixed multiple-dose regimen, the blood levels of drug eventually reach a steady state in which the blood level time curve during any dosage interval is the same as it is in the preceding and in the following dosage interval. One may define the equilibrium state as that in which input of drug to the 'body' is equal to output of drug from the 'body' in a given dosage interval. The same equilibrium state will be reached when the initial dose is higher than the maintenance dose<sup>4</sup>.

These concepts were studied with an analogue computer applied to analysis of compartment models. The analogue computer studies led to an equation which can be used to predict the average asymptotic blood levels during a multiple-dose regimen from basic parameters estimated from single-dose studies. The equation also has been derived mathematically.

The equation is:

$$\bar{O} = FD/VK\tau \quad (1)$$

where  $\bar{O}$  is the average asymptotic blood (serum or plasma) concentration,  $D$  is the dose (weight) given at the beginning of each dose interval,  $\tau$  is the length of the dosage interval,  $K$  is the first-order rate constant for overall loss of drug from the blood,  $F$  is the fraction of each dose which is absorbed, and  $V$  is the apparent volume of distribution of the drug.

$\bar{O}$  is defined as follows:

$$\bar{O} = \frac{1}{\tau} \int_{t_1}^{t_1+\tau} O_{\infty}(t) dt \quad (2)$$

where  $t_1 - t_1 = \tau$  and  $O_{\infty}(t)$  is the blood level at time  $t$  during the equilibrium state.

Equation (1) will hold under the following conditions: (a) transfer from the blood is first order; (b)  $F$ ,  $D$ ,  $V$ ,  $K$  and  $\tau$  are constants for each dose of the multiple-dose regimen in a given subject or patient; and (c) input to the blood and transfer from the blood to any number of possible compartments and back to the blood may be described by a system of simultaneous linear differential equations.

Under these conditions, it can be shown that, following a single dose of drug:

$$FD = VK \int_0^{\infty} O(t) dt \quad (3)$$

This equation is implicit in the work of Teorell<sup>11</sup> and Dominguez<sup>12</sup> and implied by many authors, for example, in clearance studies<sup>13,14</sup>.

Combining equations (1), (2) and (3) gives:

$$\int_{t_1}^{t_1+\tau} O_{\infty}(t) dt = \int_0^{\infty} O(t) dt \quad (4)$$

Hence, under the conditions stated here, the area under the blood-level curve during a dosage interval at the steady state will be equal to the area under the single-dose blood-level curve.

The  $\bar{O}$  level expected on a given multiple-dose regimen of dose,  $D$ , every  $\tau$  hours may be predicted from single-dose blood-level data by obtaining  $FD/V$  and  $K$  from the single-dose data, then using equation (1).  $K$  may be estimated from the terminal linear segment of a semilogarithmic plot of blood (serum or plasma) concentrations versus time. Under the assumptions stated by Wagner and Nelson<sup>15</sup>,  $FD/V$  may be estimated by the equation:

$$\frac{FD}{V} = \frac{1}{n} \sum_{i=1}^n \left\{ O(T_i) + K \int_0^{T_i} O(t) dt \right\} \quad (5)$$

where  $T_i$  and  $O(T_i)$  represent the time and observed blood levels for the  $n$  points used to estimate  $K$  and the integral

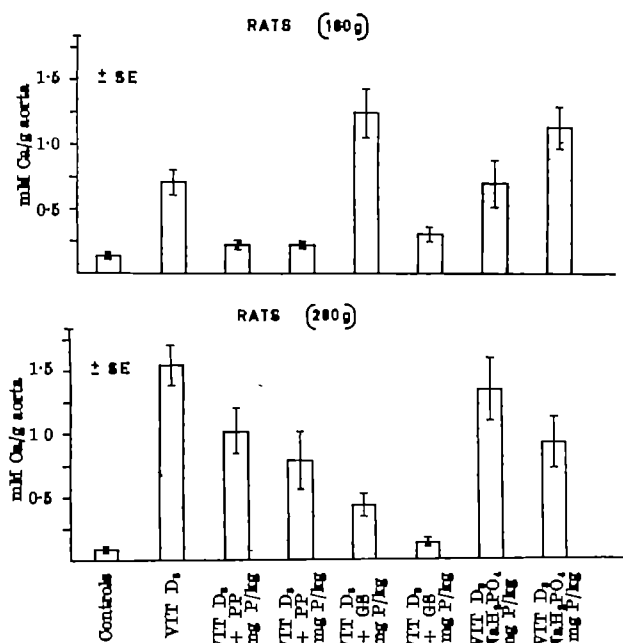

Fig. 1. Effect of pyrophosphate (PP), Graham salt (GS) and orthophosphate on the aortic calcification produced by vitamin D<sub>3</sub> in young and old rats. Each group contained 10 animals.

calcium analysis. Aortas from animals successfully treated with polyphosphates also showed no abnormalities in morphological appearance after periodic acid-Schiff and alcian blue staining.

Interesting differences seem to exist in the responses of the animals at different ages. Pyrophosphate was more effective than Graham salt in the young animals, but the reverse was true in the older animals in whom the response to pyrophosphate was only slight. It would be interesting to know whether this apparent resistance of the older animals to the physiological inhibitor pyrophosphate is of any relevance in the development of pathological calcifications in the aged.

The experiments show that condensed phosphates can prevent calcification in the aorta, and are therefore effective *in vivo* as well as *in vitro*. This property might perhaps have a place in the future in the prevention of heterotopic calcification.

Table 1. PHENOMENA WHICH WILL INVALIDATE EQUATION (1)

Phenomenon	Expected or known result
1. Plasma level of drug exceeds protein binding capacity	$K$ increases and $V$ decreases at high blood levels
2. Distribution increases at higher blood levels	$K$ may decrease or increase, and $V$ increases at high blood levels.
3. An enzyme system metabolizing the drug becomes saturated at high blood levels	Order of elimination from the 'body' may change from apparent first order to apparent zero order.
4. The drug's metabolism is stimulated by the drug itself or by another agent	$K$ increases and $V$ remains constant.
5. The drug's metabolism is inhibited by another agent	$K$ decreases and $V$ remains constant.
6. Diffusion equilibrium is not maintained between drug in blood and drug in other fluids of distribution	
7. The fraction of the dose absorbed decreases as the dose is raised due to a low rate of dissolution and relatively fixed transit time in the gastrointestinal tract	$F$ will decrease as $D$ is increased.

is the cumulative area under the blood-level time-curve from time zero to time  $T_1$ .

There are several known phenomena which invalidate the use of equation (1). These are listed in Table 1.

Equation (1) predicts that  $\bar{O}$  will be directly proportional to the dose on a multiple-dose regimen where the doses are given at regular intervals of  $\tau$  h. If the observed  $\bar{O}$  levels are not directly proportional to the dose administered, then one or more of  $F$ ,  $K$ , and  $V$  are suspect as not being constant. One, two or all three of these may change with increasing dose and/or blood level. Then additional studies are indicated to determine which factor or factors cause the lack of proportionality.

If equation (1) is applicable, the slope of the  $\bar{O}$ ,  $D$  linear plot will be  $F/VK\tau$ . If the drug is given intravenously, then  $F=1$  and the slope will be  $1/VK\tau$  from which the metabolic clearance rate,  $VK$ , may be obtained. The ratio of the slope obtained by the non-intravenous route to the slope obtained by the intravenous route will yield the fraction,  $F$ , of the dose absorbed following the non-intravenous route. With drugs that are excreted in the bile and which also yield measurable blood levels, a material balance obtained by measuring 'unchanged' drug in the blood, urine and faeces does not provide data to assess the extent of drug absorption. This is obvious since drug measured in the faeces may have been totally or partly absorbed and excreted in the bile, to appear in the faeces if not reabsorbed. Hence, one cannot distinguish drug in the faeces which has been absorbed from drug which has passed directly through the gastrointestinal tract. The method outlined above circumvents these pitfalls but, of course, it depends on the validity of equation (1).

Equation (1) is also useful, if shown to be valid for a particular drug, to predict change in  $\bar{O}$  with change in dosage regimen. One can insert various pairs of  $D$  and  $\tau$  values, and, with  $F/VK$  calculated from the slope of the  $\bar{O}$ ,  $D$  plot originally investigated, calculate the predicted  $\bar{O}$  level for each pair of  $D$  and  $\tau$  with equation (1). Such estimations may constitute a great saving in time and money compared with a trial and error empirical method.

The average asymptotic blood level for a given dose is independent of the rate of absorption in those cases where equation (1) applies. The analogue computer studies indicated that the more rapid the rate of absorption, the greater the variation of the blood levels about  $\bar{O}$  during a dosage interval. Equation (1) also indicates that  $\bar{O}$  is inversely proportional to  $K$  or directly proportional to the biological half-life of the drug,  $t_{1/2}$ , in a particular individual. Since there is considerable variation in biological half-life from subject to subject with a given drug<sup>18</sup>, one can expect a similar variation in  $\bar{O}$  levels. These considerations may be of importance in comparing blood-level results following 'sustained release' or prolonged action preparations of a drug with those following conventional dosage forms. No clear-cut distinction may exist in a multiple-dose study even when one has been observed in a single-dose study.

Since  $t_{1/2}=0.693/K$ , one can re-write equation (1) as follows:

$$VO = \frac{1.44 F D t_{1/2}}{\tau} \quad (6)$$

where  $VO$  is the average amount of drug in the 'body' during a dosage interval at the steady state. When equation (1) is shown to apply for a given drug, some interesting rules are evident from equation (6). If  $\tau=t_{1/2}$ , then  $VO$  is 1.44 times  $FD$  or that amount of drug which reaches the circulation after a single dose. Corresponding values of  $VO/FD$  for selected  $\tau/t_{1/2}$  ratios are:

Dose interval $\tau$ in multiples of $t_{1/2}$ ( $\tau/t_{1/2}$ )	Ratio of asymptotic amount in body to amount absorbed from each dose ( $VO/FD$ )
1	1.44
2	0.72
4	0.36

The extent of accumulation in the 'body' of a drug having a long half-life and administered frequently can be readily gauged by use of equation (6). If a drug with a half-life of 72 h is given twice a day, then  $VO=8.64 FD$  provided the above conditions hold. Once the biological half-life of a drug in a panel of human subjects is known, then equation (6) may be utilized to provide initial estimates of drug accumulation with different projected dosage regimens.

### Altered Cardiac Retention of Exogenous Noradrenaline produced by Stress in Young Rabbits

An impressive body of evidence indicates that cardiovascular reactivity either to sympathetic nerve stimulation or to injected catecholamines is considerably decreased in

adrenalectomized animals<sup>1</sup>. The administration of adrenocortical hormones to such animals either improves or restores to normal the ability of the cardiovascular system to respond either to sympathetic nerve activity or to the injection of adrenaline or noradrenaline<sup>1</sup>. These considerations suggest that one result of stress-induced adrenocortical secretion in normal animals might be an enhanced response of the cardiovascular system to the catecholamines. In support of this idea, it has been reported<sup>2</sup> that hydrocortisone increased the response of rabbit aorta to noradrenaline *in vitro*. Such potentiation could be caused by a decreased tissue-binding (that is, functional inactivation) of administered noradrenaline produced by the steroid. This suggestion was investigated by examining the influence of administered hydrocortisone on the sub-cellular distribution of tritiated noradrenaline in the rabbit heart.

Rabbits received four intraperitoneal injections, each of 10 mg of hydrocortisone sodium succinate/kg body-wt. (in a volume of 0.1 ml./kg) at hourly intervals. Fifteen min after the last injection, each animal was given an intravenous injection of 2 µg of *DL*-noradrenaline-7-<sup>3</sup>H per kg (specific activity 4.72 c./mmole). The hearts were removed 30 min later, homogenized in six volumes of 0.3 M sucrose and the homogenate was centrifuged at 135,000*g* for 30 min. The noradrenaline-<sup>3</sup>H contents of the resulting supernatant fluid and the crude particulate fractions were estimated, after extraction of each with 0.4 M perchloric acid, using methods described previously<sup>3</sup>.

Preliminary experiments revealed a significant decrease in both the supernatant and particulate noradrenaline-<sup>3</sup>H of heart homogenates after hydrocortisone treatment. An identical effect was seen in another group of animals that received intraperitoneal injections of saline (0.1 ml./kg), instead of the hydrocortisone. Furthermore, it was noted in these early experiments that this effect was only seen when young (approximately 500 g) animals were used. Accordingly, subsequent studies (those forming the basis for this communication) were conducted using only young (age 3-4 weeks) rabbits, the weight-range of which was 470-700 g. Four such animals were used in each of the nine experiments forming series 1 (Fig. 1). A random selection procedure determined the treatment given each animal. In these experiments (Fig. 1), the particulate noradrenaline-<sup>3</sup>H was significantly ( $P < 0.01$ ) reduced by each of the treatments used; the supernatant amine content also was significantly lowered after the previous injection of either hydrocortisone ( $P < 0.01$ ) or saline ( $P < 0.05$ ), but not by that of ACTH (included in this series to mimic the effect of a possible stress-induced endogenous secretion of this hormone). It was apparent that neither hydrocortisone nor ACTH administration had a greater effect than successive intraperitoneal injections of saline.

Experiments similar to those of series 1, carried out with older rabbits (age 11-13 weeks; weight 1.1-1.7 kg), revealed no alteration of the sub-cellular distribution of cardiac norepinephrine after any of the treatments.

The fact that, in young animals, the intraperitoneal injection of either saline or the stress and handling associated with its administration caused the altered distribution of noradrenaline-<sup>3</sup>H suggested that the mechanism might involve stimulation of either the pituitary-adrenal axis or the activation of the sympatho-adrenal system. In either event, the effect should be reduced or abolished by anaesthesia. Experiments were carried out (series 2, Fig. 1), therefore, using rabbits anaesthetized with dialurethane (0.5 ml./kg). Unfortunately, it was impossible to maintain young rabbits under anaesthesia for the total experimental period (4 h 45 min) used in series 1. Accordingly, intraperitoneal injections of either saline (0.1 ml./kg) or hydrocortisone sodium succinate (10 mg/kg) were given four times at intervals of 30 min. The remaining experimental procedure was identical with that described for series 1. It can be seen (series 2, Fig. 1) that in anaesthetized animals hydrocortisone appeared to reduce the amount of particulate-bound noradrenaline-<sup>3</sup>H, when compared with that of saline-treated rabbits, although the decrease was not statistically significant. The supernatant noradrenaline-<sup>3</sup>H was uninfluenced by hydrocortisone. Anaesthesia *per se* had no observable effect on amine retention (using the mean figure for the control, conscious animals of series 3). The latter control figures were used to judge the influence of anaesthesia, since the experiments comprising series 2 and 3 were carried out simultaneously.

Large volumes (50 ml. and above) of saline, injected intraperitoneally, are known to cause adrenocortical activation<sup>4</sup>. It seemed unlikely that only 0.4 ml./kg injected in the work recorded here could be responsible, *per se*, for the observed effect on the retention of noradrenaline-<sup>3</sup>H. This possibility was examined in experiments (series 3, Fig. 1), however, in which a group of animals each received 4 mock injections (consisting of the passage of a hypodermic needle through the abdominal wall) at hourly intervals, prior to the administration of noradrenaline-<sup>3</sup>H as already described. Such mock intraperitoneal injections significantly ( $P < 0.01$ ) reduced the noradrenaline-<sup>3</sup>H of both supernatant and particulate fractions of heart homogenates. The fact that mock injections are just as effective in this regard as intraperitoneal injections of saline (series 3, Fig. 1) establishes unequivocally that the mechanism responsible for the effect is initiated by the stress and handling attendant on intraperitoneal injection in young rabbits.

Table 1. PERCENTAGE DECREASE IN THE MEAN NOREPINEPHRINE-<sup>3</sup>H OF SUPERNATANT AND PARTICULATE FRACTIONS OF SUCROSE HOMOGENATES OF HEART FOLLOWING VARIOUS TREATMENTS OF YOUNG RABBITS

Series	Treatment	Interval between injections (h)	Anaesthesia	% Reduction appropriate control = 100% Super- natant	Particulate
1	4 i.p. injections of saline	1	None	30	44
	4 i.p. injections of hydrocortisone	1	None	39	51
	4 i.p. injections of ACTH	1	None	11	37
2	4 i.p. injections of hydrocortisone	0.5	Yes	4	22
3	4 i.p. injections of saline	1	None	45	60
	4 mock injections (i.p.)	1	None	58	57

Table 1 indicates that, with the exception of the experiments where 4 mock injections were given, all treatments reduced the mean particulate noradrenaline-<sup>3</sup>H content more than that of the supernatant fractions.

These studies serve to draw attention to the importance of stress as a determinant of the retention of noradrenaline by the heart of the young rabbit; they do not, however, indicate the precise mechanism or mechanisms that may be responsible for the effect. The fact that intraperitoneally administered ACTH was no more effective than saline (series 1, Fig. 1) suggests that if pituitary-adrenocortical activation mediated the depressed noradrenaline-<sup>3</sup>H retention, then such activation may be

Fig. 1. The retention of noradrenaline-<sup>3</sup>H by supernatant and particulate fractions of sucrose homogenates of rabbit heart. The vertical bars describe the standard error of the mean values for retention. The figure (n), below each series, refers to the number of animals subjected to each of the treatments used. White, supernatant; hatched, particulate

maximal with the stress alone (that is, saline or mock injections). A second factor which may be involved in producing the observed effect is a stress-induced sympatho-adrenal activation. If the blood levels of catecholamine during the stress reached sufficiently high levels and were maintained until the injection of noradrenaline- $^3\text{H}$ , it is conceivable that competition for uptake sites took place, since both adrenaline and noradrenaline are bound by the same sites in heart<sup>5</sup>.

I thank Dr. S. Stubbs, of the Upjohn Co., Kalamazoo, Michigan, for supplies of both hydrocortisone sodium succinate and ACTH, and Miss P. Cunningham and Miss J. Bach for their assistance. This work was supported by U.S. Public Health Service grant H-7249, from the National Heart Institute.

## PATHOLOGY

### Serum Protein Changes associated with *Oesophagostomum columbianum* Infections in Sheep

THE separation of serum proteins by paper electrophoresis has been used widely in human medicine and for diagnostic purposes by veterinarians<sup>1</sup>. Parasitologists are also finding increasing use for electrophoretic techniques in the analysis of helminth infections<sup>2</sup>. In the following study the distribution of serum proteins of non-infected sheep maintained worm-free from birth, and worm-free sheep experimentally infected with 2,000 *Oesophagostomum* larvae, was analysed electrophoretically.

Blood samples were obtained from all the control and infected animals at intervals of between four and seven days by jugular puncture. The serum from these samples was stored at  $-20^{\circ}\text{C}$  until used. Total protein estimations were made using the Biuret method and a Beckman 'DU' spectrophotometer<sup>3</sup>. Electrophoretic separation of the individual proteins was obtained using Oxoid cellulose acetate strips and a barbiturate buffer, pH 8.6, 0.07 M at 0.5 m.amp/cm width of strip for 1.5 h runs<sup>4</sup>. The dried strips were stained using bromo phenol blue in 5 per cent acetic acid; the stained strips were washed in four successive changes of 5 per cent acetic acid, dried and cleared in white oil (Shell) and scanned using an 'EEL' scanner. The proportion of the individual proteins was ascertained from the scanner drawings. The form of these patterns is shown in Fig. 1.

Campbell<sup>5</sup> obtained four serum fractions from normal sheep using paper electrophoresis, namely, albumin,  $\alpha$ ,  $\beta$ , and  $\gamma$  globulins. By the use of cellulose acetate the  $\beta$  fraction was split into  $\beta_1$  and  $\beta_2$  components; each of the other separated proteins and the  $\beta_1$  and  $\beta_2$  together agree closely with the proportion allotted by Campbell<sup>5</sup> (Table 1).

In the control animals the serum patterns can be noted to change provided the observations are spread over a long enough period. There is, however, little change in the albumin and  $\alpha$  globulin content as expressed in g per cent, more notably the  $\beta_1$ ,  $\beta_2$  and  $\gamma$  globulins increase gradually, particularly the  $\beta_2$  and  $\gamma$  globulins (Table 1 shows the average values seven weeks apart).

After infection with *O. columbianum* the total protein value generally begins a slow decline. This slow decline is

due to a complex of changes, occurring all at once, involving a loss of serum albumin,  $\alpha$  and  $\beta_1$  globulins, and an increase in the  $\beta_2$  and  $\gamma$  globulin content of the serum. The actual loss of serum albumin is generally quite massive, involving as it does a loss of up to 1 g per cent. This loss is related to the dehydration caused by the infection through water loss in the faeces, which may increase by as much as 30 per cent over the normal value. Loss of water is important since albumin is re-cycled through the lumen of the gut<sup>6</sup>; the inability of the infected sheep to re-absorb water results in the loss of a great deal of the re-cycling albumin.

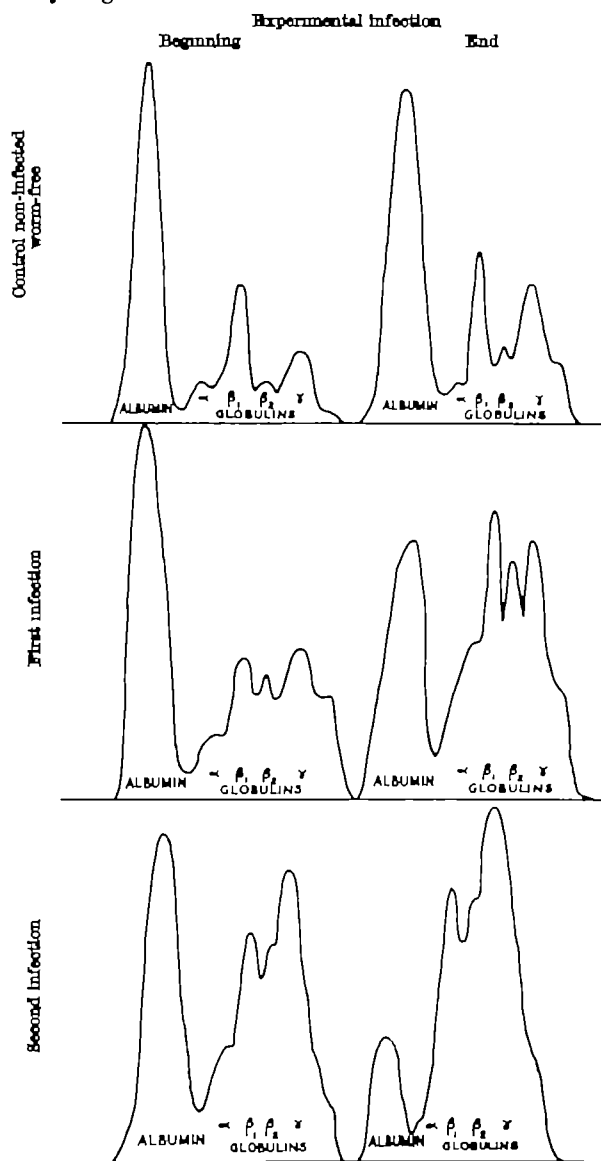

Fig. 1

Immunological activity by the host is indicated because there is a large increase in the globulin fractions, particularly  $\beta_2$  and  $\gamma$  globulins, both of which are known to contain antibody<sup>7</sup>. Proportionately there is a greater percentage increase in the  $\beta_2$  globulin fraction than the  $\gamma$  globulin. This was more evident after primary than after secondary infection. This may indicate an inordinate involvement of  $\beta_2$  substances in the resistance of the host to new nematode infections (Table 1). An anamnestic response was observed after secondary infection when the  $\gamma$  globulin fraction increased by 1 g per cent within one week. The  $\beta$  globulins were not affected in this way although there was a large but gradual increase. Comple-

## Culture in London Study in Melbourne

An efficient method of transporting living cells and other specimens has become one of the biologists' most urgent needs. Now Union Carbide has developed a revolutionary new range of biological transporters embodying a unique principle of cryogenic storage which enables the temperature of the specimens to be kept below  $-130^{\circ}\text{C}$  for up to five days: long enough for a train journey across Europe or a freight flight from London to Australia. The new transporters consist of an aluminium outer shell with a plastics lining containing a porous specimen holder drilled to accommodate the

specimen ampoules. This holder is saturated with liquid nitrogen which gradually evaporates and is exhausted to atmosphere through pressure relief vents. The porous specimen holder eliminates the danger of spillage, and Super Insulation reduces the evaporation rate to 0.33 litres per day in the case of the BT-2 and 0.36 litres per day in the case of the larger capacity BT-3. Porous holders can be supplied to fit any shape of specimen container. Since the BT-2 holds 1.6 litres of nitrogen and the BT-3 2 litres, both transporters have a guaranteed static holding time of 5 days.

### E & M's Newest Pressure Transducer The Linear-Core™ Model P-1000

The first in a wholly new series of force and pressure transducers is now available, featuring wide range, low volume displacement and a high overload factor. It reduces the per channel cost of pressure recording, since the pre-amplifier is required. Designed to operate with the PHYSIOGRAPH, the Linear-Core™ Model P-1000 provides maximum sensitivity of 4 mm Hg/cm per deflection. The overall range is from 100 to over 1000 mm Hg. Volume displacement 0.7 mm<sup>3</sup> per 100 mm Hg. Maximum overload 4000 mm Hg. Internal calibration 10 and 100 mm Hg. Linearity and hysteresis  $\pm 0.5\%$  of selected range. E & M Instrument Co., Inc., 6430 England St., Houston, Texas 77021.

### E & M's New Isotonic Myograph

Linear displacement transducer for smooth muscle and other constant tension studies. No internal systems or friction, minimal system inertia, internal calibration. E & M Instrument Co., Inc., 6030 England St., Houston, Texas 77021.

ment-fixation titres of these sera show that the peak of γ globulin content of the serum occurred at the same time as the highest complement-fixation titre on both first and second infection.

Preliminary analysis of the mucus from immune animals indicated that there are large amounts of β1 and β2 globulin in these intestinal exudates and that the migration of the β2 fraction may be inhibited by the addition of specific somatic antigens prepared from the disintegrated third-stage larvae of *O. columbianum*.

### Effect of Treatment with 2-Mercaptoethanol on Tanned Red Cell Agglutinating Antibodies In Allergic Encephalomyelitis

It has been shown that guinea-pigs and other animals injected with brain and Freund's complete adjuvant produce antibodies, both of complement-fixing and agglutinating type<sup>1,2</sup>. These antibodies react with homogenates or extracts of brain and also with purified encephalitogenic agents of the basic protein type; in this study only the anti-basic protein response has been evaluated.

Harwin and Paterson<sup>3</sup> found that in rats with allergic encephalomyelitis, complement-fixing activity of the serum was associated with 19S globulins and was destroyed by treatment with 2-mercaptoethanol. Serum with high complement-fixing activity when passively administered showed suppressive effects against the disease.

Table 1. AGGLUTINATING ANTIBODY IN SERA OF GUINEA-PIGS WITH ALLERGIC ENCEPHALOMYELITIS BEFORE AND AFTER TREATMENT OF SERA WITH 2-MERCAPTOETHANOL (BAL)

GP	Titres (tubes of doubling dilution)

2431	4	7	8	7
2237	1	2	6	8
2234	2	1	6	8
2434	4	6	8	8

NT: not tested.

It was thought of interest to investigate the presence of antibodies to a purified encephalitogenic basic protein (EF) of human brain<sup>4</sup> and also to a similar, but inactive, product derived from human sciatic nerve (SNBP) before and after treatment with 2-mercaptoethanol since this treatment is reported to inactivate 19S-type antibodies<sup>5,6</sup>. Sera were mixed with an equal volume of 0.2 M 2-mercaptoethanol left at 18° C for 24 h and the reagent removed by dialysis against normal saline for a minimum of 3 days at 4° C. Results of the antibody titrations before and after treatment are shown in Table 1. Antibody titre was not markedly reduced in any specimen; on the contrary, higher titres were obtained in a number of cases.

These results suggest that direct agglutinating antibody is of the 7S type. Because of the increase in titre shown in some cases it may be that treatment with 2-mercaptoethanol can liberate direct agglutinating fragments from non-agglutinating 19S antibodies present. Treatment with 2-mercaptoethanol did not influence the course of allergic encephalomyelitis in the 'guinea-pig'. Protection experiments carried out by pre-immunizing guinea-pigs with encephalitogen either in saline or in incomplete Freund's adjuvant gave high titre antibody of both types in each case but high protection only by immunization using the antigen in incomplete adjuvant. This suggests that either the 7S or 19S antibody to the active agent is directly associated with protective activity or that the protecting antibody may be directed against an inactive contaminant associated with the encephalitogen, enabling this to be cleared from the system before it can produce disease.

### Stimulation of Mast Cell Production in Lymph Nodes of the Rat by Pyrrolizidine Alkaloids

MAST cells are known to increase in some tissues under certain conditions often associated with an immunological component. Well-known examples are in the skin in the vicinity of induced epitheliomas in mice<sup>1</sup> and associated

with proliferative changes in the thymus of *NZB* mice<sup>3</sup>. In lymph nodes, where under normal conditions mast cells occur in small numbers only, Miller<sup>4</sup> observed an increase in mast cell numbers after injection of *Salmonella* antigens, and Takeoka *et al.*<sup>5</sup> noted a significant increase in mast cells in the lungs and mediastinal lymph nodes in rats being fed seeds of *Crotalaria spectabilis* or the pyrrolizidine alkaloid, monocrotaline, isolated from this plant.

Because we have been investigating for some time the wide range of biological activities displayed by this group of alkaloids<sup>6</sup>, we have examined the effects on mast cells in the lymph nodes of rats given repeated small intraperitoneal doses of the three alkaloids heliotrine, lasiocarpine, and supinine which occur in *Heliotropium europaeum*<sup>6,7</sup>. Solutions of the hydrochlorides of these bases were used for all injections. The acute 72-h  $LD_{50}$  doses are 296, 77 and 405 mg/kg respectively<sup>8</sup>. In the current experiment groups of rats of a hooded strain<sup>9</sup> were given 0.1  $LD_{50}$  of heliotrine or lasiocarpine or 0.2  $LD_{50}$  supinine by intraperitoneal injection three times per week for 14 weeks. At necropsy, para-aortic lymph nodes and thymus were taken into Zenker fixative. Histological examination of paraffin sections stained with toluidine-blue and Unna-Pappenheim stain shows that there is a high mast cell count in the lymph nodes in 9 of 10 rats in the lasiocarpine group. Two only of 9 rats given heliotrine and none of 5 rats given supinine had a higher-than-normal mast-cell count in these lymph nodes. A comparison of the proportions of 'high' counts shown in Table 1 for the three alkaloids was made by computing chi-squared for the table and testing its significance. The value was significant at the 1 per cent probability level and it is clear that the frequency is highest for lasiocarpine. Mast cells were not found in the thymus with any of the alkaloids.

From a comparison of sections stained with haematoxylin-eosin, Unna-Pappenheim stain or toluidine-blue, it is clear that the mast cells appearing within the lymph nodes of animals given lasiocarpine are significantly different in appearance from those seen in connective tissue at the periphery of the nodes or in subperitoneal tissue.

In general the mast cells in the lymph node substance are larger, cuboidal rather than elongate in shape and stain less heavily with toluidine-blue. The mast cells are mostly in the usual areas where they are found after antigen stimulation<sup>10</sup> and, although they are close to medullary cords containing many plasma cells, they are in the intervening lymph spaces among the large number of reticulo-endothelial cells which often contain blood pigment. There is an impression that mast cells are especially

Table 1. MAST CELL COUNTS IN AORTIC LYMPH NODES OF RATS GIVEN REPEATED SMALL DOSES OF PYRROLIZIDINE ALKALOIDS

Alkaloid	No. of rats	Mast cell counts*	
		Individual	Proportion high
Lasiocarpine	10	0, 90, 100, 112, 125, 150, 165, 175, 200, 220	9/10
Heliotrine	9	0, 0, 0, 0, 0, 0, 8, 140, 160	2/9
Supinine	5	0, 0, 0, 4, 12	0/5

\* Each number is the mean of counts of two high-power fields of the same section from one rat. High-power field = 0.07 mm<sup>2</sup>.

abundant where the lymph channels are blocked by reticulo-endothelial cells. At these points there are plasma cells and lymphocytes in the channels and the possibility of origin of mast cells from lymphocytes via pyroninophil cells cannot be excluded. It is equally possible, however, that they may be derived from local reticulo-endothelial cells or have reached their characteristic situation from somewhere else in the body. In all the lymph nodes examined, all primary and secondary follicles are devoid of mast cells.

We thank Sir Macfarlane Burnet, who suggested this investigation.

## IMMUNOLOGY

### Antibody Production in Mice with Isologous Tumours

THIS communication presents the results from experiments on the production of humoral antibodies by mice growing isologous transplantable tumours. The ability to produce antibodies by human cancer patients has been extensively investigated in recent years, and it has been shown that this ability is significantly depressed in patients with malignant disease<sup>1</sup>. Fewer observations have been made on the antibody production by experimental animals with tumours. Bogden and Aptekman<sup>2</sup> have demonstrated a reduction in the naturally occurring heteroagglutinins in mice with tumours, and Parfentjev *et al.*<sup>3</sup> have shown that the *proteus* agglutination titre is reduced in chickens with the Rous sarcoma. In an attempt to find an experimental model similar to the human situation, the production of humoral antibodies by two strains of mice growing transplantable isologous tumours has been investigated.

Groups of *A* strain mice with a transplantable mammary tumour (*AMT3*) and *O67* strain mice with a transplantable epithelioma (*Ep6*) were used. Tumours were transplanted by the subcutaneous injection on the back of a standard dose of tumour suspension. After 9 days the mice were immunized with 0.2 ml. *Salmonella typhi* 'H' antigen intraperitoneally and were bled 9 days later. Equal volumes of sera from two or three mice were pooled and the titre of antibody present in the pooled sera determined by the Vidal agglutination technique. Tumours were approximately 10 × 10 mm when antigen was given and 22 × 22 mm at the time of bleeding. Groups of normal

Tumour	12	5.7
Control	12	6.0

mice immunized and bled at similar times served as controls. Titres of antibody are expressed in this report as log<sub>10</sub> reciprocals of the end-point dilution.

Results in A and O57 mice with tumours and control mice are given in Table 1.

These results show no significant difference in antibody production between the control group and tumour mice.

Two groups of A strain mice were immunized with 0.2 ml. H antigen intraperitoneally and 6 weeks later tumour suspensions were transplanted to one group. A second injection of 0.2 ml. antigen was given to both groups intraperitoneally 9 days later. After 9 days the mice were bled and antibody titre determined. A similar experiment was carried out with O57 mice and the results are shown in Table 2.

It can be seen from these results that the tumour-bearing mice responded as well as the control mice.

A study was made to observe the effect of vaccination with BCG on antibody production by groups of control and tumour mice. BCG has been shown to increase both antibody production and phagocytic activity in normal mice<sup>4</sup>. Two groups of mice were pre-treated with three daily injections of 1 vial BCG vaccine and 2 weeks later one group was injected with tumour suspension. Nine days later the mice received 0.2 ml. antigen intraperitoneally and were bled 8 days later, and antibody titres determined. The results are shown in Table 3.

Again there is no difference in antibody titre between the two groups.

The experimental system used is based on the procedure used by Berenbaum<sup>5</sup> for investigating the effect of various immunodepressant agents on antibody production. A single antigen has been used in these experiments instead of the TAB vaccine in which the 'H' antigenic potency of different samples is variable. Primary immunization was examined as it is believed to be more easily depressed than secondary immunization, delayed hypersensitivity reactions or homograft rejection. In certain human tumours there is evidence for the presence of cancer-specific antigens<sup>6</sup>. An attempt has been made to demonstrate possible cancer-specific antigens in the tumour AMT3. Antisera were prepared in rabbits by immunization on two occasions with a saline extract of AMT3 tumour with Freund's complete adjuvant. The antisera were tested by the Ouchterlony double-diffusion technique for reactions with a saline extract of tumour tissue and a saline extract of normal breast obtained from a lactating isologous mouse. After staining, no extra line was present opposite the tumour cells.

There is therefore no evidence of a soluble cancer-specific antigen in this tumour to give rise to antigenic competition, and this may explain the normal immunological activity of the tumour mice. Part of the depression of antibody formation seen in human cancer is believed to be due to the action of a specific depressing agent rather than secondary to the effects of cachexia and starvation, and a tolerance agent has been isolated from certain tumours<sup>7</sup>.

Although splenomegaly occurs in these mice with tumours<sup>8</sup>, Perovsky<sup>9</sup> has shown changes in the serum  $\gamma$ -globulins with isologous tumours of mice; the groups of mice studied with a well-developed tumour showed no evidence of an inability to respond to a foreign antigen,

and this may be due to a lack of antigenic competition with a cancer antigen in the tumour.

This work was carried out during the tenure of a grant from the British Empire Cancer Campaign for Research. I thank Prof. J. G. Murray for his advice and Messrs. Burroughs Wellcome for a supply of *Salmonella typhi* 'H' antigen.

### Haemagglutinating, Precipitating and Lymphocyte-stimulating Factors of Phytohaemagglutinin

EXTRACTS from certain seeds of the Leguminosae are known to possess interesting biological properties. An extract of *Phaseola vulgaris*, phytohaemagglutinin (PHA), agglutinates red and white blood cells<sup>1,2</sup> and tumour cells<sup>3</sup>, and indiscriminately stimulates blood lymphocytes cultured *in vitro* to undergo blastie transformation and increased mitogenic activity<sup>4</sup>. Since lymphocytes of a sensitized donor are known to be stimulated in the same manner when exposed to a previously encountered antigen<sup>5,6</sup>, the possibility of PHA being a universal antigen has been considered<sup>7</sup>. Recently it has been noted by ourselves and others<sup>8,9</sup> that PHA likewise forms a precipitate indiscriminately with serum. Our demonstration of this ability of PHA to form a precipitin line with human serum and numerous animal sera appeared to support the concept of its being a ubiquitous antigen. If this were a valid concept, however, treatment of PHA to remove its precipitating activity would entail loss of antigenicity and might be expected to impair the lymphocyte-stimulating factor as well.

The purpose of this report is to describe the effect of heat and absorption with red blood cells on the precipitating and lymphocyte stimulating activity of PHA and to present evidence that PHA functions as a precipitating agent rather than an antigen when reacted with protein by diffusion in solid media.

Commercially available PHA (Burroughs Wellcome 'K 4597' and 'K 4912') was used throughout the experiment. PHA was absorbed three times with 0.5 ml. of washed, packed human red blood cells for 30 min. Heat inactivation of PHA was by heating at 85° C for 5 min as described by Tunnis<sup>10</sup>. Washed, packed normal rabbit red blood cells were used in the haemagglutination tests. The method for haemagglutination was essentially that described by Boyden<sup>11</sup> except that the tanned cells were not sensitized. The micro-Ouchterlony technique of Crowle<sup>12</sup> was used for the precipitin test. Lymphocyte cultures were prepared with media containing 'TC 199', foetal calf serum, penicillin and streptomycin. Cultures were maintained at 37° for 72 h in a tightly closed screw-top bottle and the percentage of blast forms was obtained by counting 1,000 lymphoid cells.

All fifty-nine human sera tested, and normal bovine, rabbit and rat sera, formed precipitates when reacted with PHA by double diffusion technique. Absorption of PHA with human red cells or heating at 85° C for 5 min destroyed this precipitating property and decreased the haemagglutinating activity. However, treatment of PHA by either technique did not affect the degree of blood lymphocyte transformation into blast forms (Table 1). Thus there appears to be no association between the

Table 1. RESULTS OF HEAT AND HAEMAGGLUTININ AND LYMOPHOYTE-STIMULATING ACTIVITY OF PHA\*

Unreated PHA			Absorbed PHA			Heated PHA		
PPTNS	HA	LS	PPTNS	HA	LS	PPTNS	HA	LS

++	7,796	64%	0	216	58%	0	216	62%
+	1,306	81%	0	216	88%	0	36	78%
+	1,306	76%	0	216	83%	0	36	74%
+	216	80%	0	36	90%	0	36	86%

The symbol HA refers to the reciprocal of the haemagglutinating titre and PHA refers to phytohaemagglutinin. LS refers to lymphocyte stimulation *in vitro* and is expressed as blast cells per 1,000 lymphoid cells in the culture.

precipitating activity and the lymphocyte-stimulating factor of PHA.

Concomitantly a large number of precipitin tests in which PHA is reacted with various sera and serum fractions indicates that the serum protein reacting with PHA is definitely not an antibody. Positive precipitin bands were formed when PHA was reacted with Cohn human serum fractions II, III, IV, VI, human albumin, serum from a child with classic primary agammaglobulinaemia and pure bovine serum albumin (BSA). The pure BSA was obtained by starch-block electrophoresis of commercial bovine serum albumin and formed a single line when reacted with rabbit anti-serum to commercial BSA on immunoelectrophoresis. Human serum albumin and Cohn fractions II, III and IV were found to contain no gamma<sub>2</sub>M, gamma<sub>2</sub>A or gamma<sub>3</sub> globulins when reacted with goat anti-human serum on immunoelectrophoresis. Demonstration that PHA forms precipitins with pure bovine serum albumin and fractions of human serum containing no immune globulins eliminates the possibility that PHA acts as an antigen in the precipitin reaction.

From these results it appears that the action of PHA in precipitating normal serum protein is not that of an antigen and thus does not support the concept that PHA stimulates lymphocyte transformation by virtue of being a universal antigen. The haemagglutinating and precipitating activity does not appear to be associated with the lymphocyte-stimulating factor in that loss of precipitating ability and marked decrease in haemagglutinin titre are not associated with a change in the ability of PHA to stimulate blood lymphocytes, cultured *in vitro*.

### An Immunogenic Fraction extracted from *Brucella abortus* Cell Walls by Phenol

AN insoluble fraction capable of absorbing the agglutinating and mouse-protecting antibodies from *Brucella suis* antisera was isolated in this laboratory from sonically disintegrated *Br. suis*<sup>1</sup>. This fraction was assumed to be part of the bacterial cell wall. Further experiments<sup>2,3</sup> showed that cell walls and cell wall fragments from *Br. abortus* and *Br. suis* protected mice against challenge with *Br. abortus* (strain '2308') more effectively than intact cells. The immunizing activity of *Brucella* cell walls was confirmed in several other laboratories<sup>4-6</sup>.

The present communication reports the preparation and activity of a purified immunogenic fraction, extracted from *Br. abortus* cell walls by phenol. Cell walls were prepared from *Br. abortus* (strain '2308'). The bacteria

were grown on trypticase soya agar<sup>7</sup> for 4 days, gathered with physiological saline and killed by ethanol 75 per cent. The killed bacteria were washed twice with distilled water and digested for 2 h with pepsin (2 mg/ml. at 52° C, pH 2.0). The insoluble residue was washed with distilled water and resuspended in water. The pH of the suspension was brought to 8.5 following which the suspension was treated with trypsin (10 mg/ml.) at 52° C for 1 h. Cell walls were isolated by centrifuging the suspension at 12,000g for 30 min. Cell walls prepared by this method showed residues of nuclear material in the electron microscope. The residues could be removed by treatment with DNase. The nuclear material was also identified by the blue colour obtained with the diphenylamine reagent for DNA<sup>8</sup>.

To 120 ml. of cell wall suspension (60 mg/ml.), 550 ml. of 90 per cent phenol solution were added in small portions, over a period of 1 h, with continuous shaking. The suspension was allowed to stand at room temperature for 48 h, then centrifuged at 27,000g for 30 min. A heavy sediment resulted. The clear supernate was dialysed against tap water for 3 days and against distilled water for 2 days. A white fluffy precipitate was obtained, which remained in suspension. In addition, a brown-coloured precipitate settled at the bottom of the dialysis bag. The suspension containing the white material was separated and centrifuged at 27,000g for 10 min. The sediment obtained was washed once with distilled water (fraction-W, white fraction). The yield was approximately 2 per cent of the total weight of intact bacteria.

The white fraction was agglutinated by anti-*Brucella* serum and could absorb completely the agglutinating antibodies from *Br. suis* antiserum. On injection into rabbits, it produced antibodies which agglutinated whole bacteria. The immunizing activity of the white fraction was compared in mice with that of cell walls and of whole ethanol-killed bacteria, against challenge with *Br. abortus* (strain '2308') as follows: groups of 10 mice were immunized intraperitoneally with 40.0, 4.0, 0.4 and 0.04 µg of the immunizing antigen, intact or disintegrated ultrasonically. At 28 days after immunization the immunized mice together with control untreated groups were challenged with 30,000 virulent *Br. abortus* (strain '2308') cells administered intraperitoneally. Spleens were counted individually at 28 days after challenge by plating on trypticase soya agar<sup>9</sup>. The geometric mean counts (GMC) and the geometric protection index (GPI) were calculated. GPI was defined as the ratio:

$$\frac{\text{Geometric mean bacterial count in the spleens of control mice}}{\text{Geometric mean count in the spleens of immunized mice}}$$

Table 1 shows that the cell walls were the most effective immunizing agent (GPI: 6,304), but fraction-W also gave a high degree of protection (GPI: 2,406). It is noteworthy that even an amount as small as 0.4 µg was still capable of giving a significant degree of protection (GPI: 75). The data obtained so far do not allow precise comparisons of

immunizing potency, but it is obvious that the activity of the white fraction was of the same order of magnitude as that of the other preparations. Further investigations are being carried out in this laboratory to determine the biological properties (toxicity, allergenicity) of this fraction. It is felt that an immunizing preparation of this type, with most of the soluble protein material removed, might be useful as a prophylactic antigen in man.

### Lysozyme and Immune Bacteriolysis

It has long been accepted that the lysis of Gram-negative bacteria by fresh serum is due to the antibody-complement system. Over the past ten years three separate groups of workers have suggested, for different reasons, that lysozyme also plays a part in immune lysis of bacteria.

Amano *et al.*<sup>1</sup> found that lysis of *Vibrio comma* by serum is accelerated by leucocyte extracts in which the active factor proved to be lysozyme. They showed further<sup>2</sup> that removal of lysozyme from fresh serum by absorption with bentonite reduces lysis but not killing of *Escherichia coli* B. Restoration of the initial level of serum lysozyme by adding egg-white lysozyme restores lytic activity. Excess egg-white lysozyme increases also the rate and extent of killing.

Knowing that both properdin and lysozyme are absorbed by zymosan<sup>3</sup>, Muschel, Carey and Baron<sup>4</sup> examined their authentic properdin and found that it contained lysozyme. Moreover, inactive properdin deficient serum (RP) could be made bacteriolytic by egg-white lysozyme.

Wardlaw<sup>5</sup>, while investigating complement bacteriolytic activity, noticed that absorbing specific antibody with large amounts of bacteria also removed lysozyme.

There is yet another way in which the role of lysozyme in the complement system may be approached. As anti-human lysozyme serum was available<sup>6</sup>, it was thought worthwhile to compare the action of serum from which lysozyme had been removed by bentonite with serum in which lysozyme activity had been inhibited by specific antibody.

Experiments were performed on log phase cultures of *E. coli* 'Lilly', a rough strain used by Wardlaw, and *E. coli* 'WF2', a smooth strain isolated in the routine diagnostic laboratory. 'WF2' has now become rough, but identical results are given by other smooth strains. Lysis was measured by the decrease in optical density of a heavy inoculum ( $8 \times 10^8$  bacteria/ml.) using a Spekker absorptiometer. Killing was measured by repeated viable counts using small inocula (5,000 bacteria/ml.).

The complement source was human serum diluted as necessary with Tris buffer pH 8.4 to give a final ionic strength of 0.06 (Wardlaw<sup>5</sup>). Anti-human lysozyme was prepared as described by Glynn and Parkman<sup>6</sup>. The rabbit lysozyme normally present in such sera was removed by bentonite and the complement inactivated by heat.

Test systems for lysis or killing were set up with the following: (1) Normal human serum (NHS). (2) Heated

human serum (RO'). (3) Normal human serum with the lysozyme removed by bentonite (RL<sub>bent</sub>). (4) Normal human serum with the lysozyme inhibited by antibody (RL<sub>Ab</sub>). (5) Heated human serum plus anti-lysozyme (RO'RL<sub>Ab</sub>). (6) 'RL<sub>Ab</sub>' plus egg-white lysozyme (EWL). (Anti-human lysozyme does not inhibit egg-white lysozyme so that this preparation had lysozyme activity.)

'Lilly' and 'WF2' give very similar results. Fig. 1 shows lysis of 'Lilly'. Fig. 2 shows killing of 'WF2'.

Normal human serum produces rapid and extensive lysis and killing. Removal of complement by heating allows rapid growth. Sera with lysozyme removed by bentonite (RL<sub>bent</sub>) or inhibited by antibody (RL<sub>Ab</sub>) produce similar results. There is initial growth, then delayed and incomplete lysis. Later experiments not shown here suggest that RL<sub>Ab</sub> is less effective in inhibiting killing than is RL<sub>bent</sub>. Addition of egg-white lysozyme (EWL) to lysozyme deficient serum restores normal killing and lysis.

Fig. 1. Lysis of *E. coli* ('Lilly') by serum  $\pm$  lysozyme

Fig. 2. Killing of *E. coli* ('WF2') by serum  $\pm$  lysozyme

In some experiments viable counts and opacity were measured in the same system, but the high inoculum needed to get a measurable opacity involves very great dilution factors in order to carry out viable counts. However, the lysis and killing curves with  $RL_{anti}$  were approximately parallel with the killing in advance of lysis.  $RL_{Ab}$  again inhibits killing to a lesser extent than does  $RL_{anti}$ .

These results, like those of previous workers, show that lysozyme is involved in serum lysis of *E. coli*. They differ from previous work in demonstrating a role for serum lysozyme in serum killing, and also in demonstrating that delayed lysis and killing occur in the absence of lysozyme or lysozyme activity. A possible explanation would be that lysozyme is released from the bacteria themselves, but none could be demonstrated. The present-day theory is that complement attached by means of antibody and antigen damages the lipoprotein and lipopolysaccharide 'layers' in the bacterial cell wall enabling lysozyme to attack the susceptible rigid mucopeptide layer underneath. All this must occur rapidly as with fresh whole serum lysis, and killing may be extensive in a few minutes. If lysozyme is removed or inactivated, presumably complement damages the outer wall as before. Possibly this sets in train some other lytic or lethal process, slower in action than lysozyme and which shows up in our curves as delayed lysis or death when the rapid lysozyme component is removed.

## RADIOBIOLOGY

### An Apparatus for Studying the Retention of Inhaled Radioactive Vapours by Human Subjects

THE retention of radioactive substances by man is a subject of major importance in the field of atomic energy both from the point of view of deriving permissible exposure-levels and also for assessing potential hazards under accident conditions. Of the limited experimental investigations carried out on man, however, the greater proportion have involved oral or intravenous administration of the radioactive substance, notwithstanding that inhalation is the commonest accidental route of entry of most radioactive substances into the human body.

In the present investigation an apparatus has been designed for the accurate determination of percentage retention of radioactive vapours when inhaled by human subjects. The first compound chosen for investigation was methyl iodide, which is of interest because it could constitute the major hazard in the release of fission products in a reactor accident<sup>1,2</sup>. The nuclide chosen for labelling was iodine-132 which is a  $\gamma$ -emitter suitable for measurement by scintillation counters outside the body; iodine-132 was used in preference to iodine-131 because the radioactive dose delivered to the thyroid by the former is about two orders of magnitude smaller than that delivered by the same amount of the latter.

The apparatus<sup>3</sup> consists essentially of six parts, as shown in Fig. 1; of these, the humidifier, mixing vessel and chimney are each self-explanatory and will not be described further.

The evaporator (b) is a small glass U-tube which is connected to the main body of the apparatus by means of a glass-glass coupling block. It can thus be easily

Fig. 1. Block diagram of apparatus. (a) Humidifier; (b) evaporator; (c) mixing vessel; (d) analysis; (e) inhalation-exhalation unit; (f) chimney leading to fume cupboard; (g) air supply

disconnected and it can also be connected in a similar manner to the exit of a gas chromatograph. The latter is used to isolate the requisite amount ( $\sim 1 \mu\text{c}$ ) of methyl iodide-132, which is prepared by a conventional exchange reaction between methyl iodide and sodium iodide-132.

It was initially intended to volatilize the methyl iodide over a period of about 15 min, but preliminary experiments showed that in order to prevent departures from normal breathing, a shorter period was desirable and the iodide was finally volatilized over 5 min only. To achieve a uniform and reproducible slow rate of release of methyl iodide-132 from the U-tube, when using very small amounts of carrier, necessitated surrounding the U-tube with a low-temperature bath. Even then, however, it was found that carrier levels of about 5 mg were required, and although these gave rise to concentrations of methyl iodide of about only 5 p.p.m., they still corresponded to a carrier uptake of twenty to thirty times the normal dietary uptake of iodine, and would have significantly affected the uptake and metabolism of the methyl iodide.

Because of this, the replacement of carrier methyl iodide by non-iodinated compounds of similar vapour pressure was investigated. Although on theoretical grounds, a diluent of this sort should have no effect on the rate of volatilization of the methyl iodide if a simple vaporization phenomenon was occurring, it was found in practice that the presence of the diluent greatly reduced the rate of loss of activity from the U-tube (this does not, however, render the method impracticable). This indicated that other phenomena such as desorption are probably predominating, but the practical implication is that the inactive methyl iodide can be largely replaced by a non-iodinated compound. In this way, iodine metabolism can be investigated under normal conditions; a second subsidiary benefit is that the somewhat toxic methyl iodide can be replaced by a relatively non-toxic compound such as methylene dichloride. Further experiments showed that if 4  $\mu\text{l}$ . of this were added to the U-tube prior to charging with methyl iodide-132, the activity was volatilized at a uniform and reproducible rate over a period of 5 min when the U-tube was surrounded by an ice/salt bath. This was verified by monitoring the U-tube with a sodium iodide crystal detector, the output from which was displayed on a recorder chart.

The concentration of the methyl iodide-132 in the main air stream is determined by drawing known volumes through small glass towers filled with charcoal, which have previously been calibrated with a solution of <sup>132</sup>I-labelled ammonium iodide of known activity.

The inhalation-exhalation assembly (e) consists basically of a large Y-piece of thick-walled glass containing a one-way valve in each of the arms. One of the arms is

connected to a ground-glass socket on the chimney and the other to another glass tower (of low resistance to breathing) containing charcoal. The subject then inhales from the chimney only and exhales to the tower only; to prevent condensation, a heating element is clamped below the exhalation arm and tower. The far side of the tower is connected to a 100 ft.<sup>3</sup> balloon, from which the volume of air exhaled, and therefore that inhaled, can be determined.

Preliminary experiments showed that there was no measurable decomposition of the methyl iodide, or adsorption on to particles, before inhalation occurred. During an inhalation experiment, the subject inhales from the apparatus during the 5 min in which the methyl iodide-132 is being volatilized and exhales during that time and a further 5 min through the tower and into the previously evacuated balloon. The amount of methyl iodide-132 which has been inhaled can then be calculated from a knowledge of its concentration in the main air stream and the volume of air inhaled, while the amount exhaled is determined by measuring the activity in the exhalation tower. The percentage retention is thus easily determined from the difference of these two quantities.

Because of the influence of inactive methyl iodide on the uptake of methyl iodide-132, the amounts of the former used as carrier in the U-tube are only of the order of 100 µg, that is, the amount inhaled is about 30–40 µg, which is considerably smaller than the normal daily dietary intake of iodides. Preliminary results on four volunteer subjects indicate values for the retention varying between 55 and 80 per cent. The metabolism of the retained methyl iodide is also being investigated and will be reported in detail in later papers.

I thank D. F. Atkins, Dr. A. E. J. Eggleton and A. Morgan for advice and Mrs. G. M. Arkell and G. Mitchell for support during the commissioning of the apparatus.

### Tracking Cobalt Project

THIS communication describes a new and accurate method of treating malignant disease by radiation. The radiotherapeutic world is convinced that accuracy in dose delivery in adequate amounts to minimum volumes has largely been responsible for improved results in limited disease. Just as surgery has its complications and rare fatal accidents, so also does a proportion of radiation injuries have to be accepted at curative dose-levels. A high standard of accuracy in treatment does much to reduce injuries by limiting the volume of tissue exposed. This new method has been the logical sequence of development over the past twenty-five years, passing through four phases.

(1) Beam directioning, by accurate 'sighting', enabled smaller radiation fields to be used without missing the primary tumour. This was first adopted for radium beam therapy<sup>1</sup>, and soon after applied to X-rays<sup>2</sup>.

(2) Further developments of methods led to the practice of uniform isodose zones enclosing the tumour, that is, the use of a pre-determined shape<sup>3</sup>.

(3) Moving-beam therapy apparatus enabled consecutive or continuous settings of radiation fields to be given with a high degree of accuracy to small zones<sup>4</sup>. This method produced mainly spheres or cylinders of pre-determined shape into which the tumour could be fitted. To extend its versatility, it was from this method that moving-beam therapy with tracking was conceived<sup>5</sup>.

(4) The cobalt tracking project will enable the spread of malignant disease from the primary growth along the

lymph node chain to be irradiated with accuracy<sup>6</sup>. A prototype apparatus at conventional voltage<sup>7</sup>, which has now been working for some years, has proved very encouraging in its use: the principal problems were solved, but owing to the distortion of the isodose pattern by bone, its future was limited. A public appeal has enabled a high quality apparatus to be made by T.E.M. Instruments, Ltd., of Crawley. The uniform dose zone of moving-beam therapy irradiates the sinuous track of the lymph node spread which is fed through it by moving the patient on a treatment couch which is guided along the track—its up-and-down and side-to-side movements being governed by electric motors, much as in the prototype design. In this instance, however, the movements are controlled by a black-on-white pattern giving the profile views of the track. Speed is shown by another series of black-and-white cut-outs which are followed by a series of photo-electric cells, that is, we have automation in radiotherapy.

The shape of the dose pattern is changed from a circle to an oval in cross-section at any point by slowing the speed of the arc movement. This allows more irradiation to that part. This is followed by acceleration of the speed which allows less irradiation; consequently an oval is produced.

Preliminary computer calculations and measurements arranged by Dr. W. A. Jennings have shown that a field of approximately 8 cm × 3 cm with reasonable definition can readily be obtained, hence the basis of attaining the principle of restricting the radiation to the diseased area while sparing the normal tissues around appears to be well within sight.

We are awaiting the construction of a room to house this apparatus so that the project may be commenced in earnest.

The expected spread of malignancy in lymph nodes, that is, the 'track', will be part of an exhibit at the International Radiological Congress in Rome in September 1965. This spread is based on information from surgeons of great operative experience and agreed by six senior United Kingdom radiotherapists. Such spread is in contrast to the post-mortem findings, when the disease is spread far and wide.

Work done at the Royal Northern Hospital has suggested that this lymph node track may be related to bony structures with a reasonable degree of accuracy and that repeat treatments may show a variation of only 0.5 cm. It is particularly fortunate that the fatty tissue which is largely responsible for the considerable variations of shape beyond the bones is, in the main, concentrated in the abdominal cavity and the superficial sites. These have no gross effect on the relation of blood and lymph vessels to the bones lying deeply in the body, hence the tracking method may prove to be valid and accurate.

### BIOLOGY

#### A Phytochrome Mediated Effect of Light on the Hydroxylation Pattern of Flavonoids In *Plum sativum* var. 'Alaska'

THE presence of a kaempferol triglucoide (KG) and a quercetin triglucoide (QG), and of their *p*-coumaric acid esters (KGC and QGC respectively), in white-light-grown 'Alaska' peas has been reported<sup>1</sup>. Evidence has also been put forward that etiolated peas contain only the

kaempferol derivatives (KG and KGC), and that low irradiances of red light cause an increased synthesis of KGC in the terminal bud<sup>1,2</sup>—this effect being reversible by subsequent irradiation with far-red light<sup>3</sup>. A role for the phytochrome system in the light-mediated synthesis of flavonoids has been proposed for several other plants<sup>4-6</sup>. In a continuation of the work of Furuya and Thomas<sup>2</sup>, we have obtained evidence that the variations in flavonoid pigments with red light are due to increases in the rate of synthesis of the quercetin derivative (QGC) while the KGC concentration, in fact, remains relatively constant. This effect on QGC synthesis is reversible by far red light and is consequently thought to be a phytochrome effect.

Initial investigations showed that good separation of the four flavonoids using the previously reported paper chromatographic method<sup>2</sup> was difficult to achieve and a method of separation based on chromatography on a silica gel column using butanol-boric acid has been developed. The amounts of KGC and QGC in the various fractions were determined by spectrophotometric assay of the coumaric acid liberated by alkaline hydrolysis.

Recovery experiments have shown that 90-98 per cent of added flavonoid is recovered by this method. Attempts to estimate the KG and QG present by an analogous technique using acid hydrolysis and estimation of the flavonoid aglycones have not so far been successful. This method of separating the kaempferol derivatives from the quercetin derivatives has the advantage of allowing the whole extract to be used, in contrast with two-dimensional paper chromatography where only a small fraction of the extract can be used. However, it has not been found possible, as yet, to separate KG from KGC, and QG from QGC, by this method.

Plants were grown in complete darkness and subjected to low irradiances of red light (1 to 1,000 kergs cm<sup>-2</sup> at 660 mμ) or far-red light (845 kergs cm<sup>-2</sup> at 740 mμ), 6 days after sowing. The terminal buds were excised under dim green light and the KGC and QGC content determined.

Table 1. KINETICS OF THE EFFECTS OF RED LIGHT IRRADIATION (327 KERG CM<sup>-2</sup>) ON FRESH WEIGHT, KGC CONTENT AND QGC CONTENT OF TERMINAL BUDS OF 6-DAY-OLD, DARK-GROWN PEAS

Time after irradiation (h)	Fresh weight		KGC		QGC	
	mg/bud	% increase	μM/g fresh wt.	% increase	μM/g fresh wt.	% increase

8	15.84	124	0.83	94	0.40	225
30	19.20	150	0.79	90	0.46	270
100	18.50	145	0.96	108	0.45	264
300	20.10	157	0.87	99	0.48	282
1,000	18.60	146	0.95	108	0.54	317

\* Dark initial = values for untreated buds at beginning of experiment.

† D.F. = dark final = dark-grown controls collected at end of experimental period.

Table 3. PHOTOREVERSIBILITY OF EFFECTS OF LIGHT ON THE FRESH WEIGHT AND QGC CONTENT OF TERMINAL BUDS OF 6-DAY-OLD PEAS GATHERED 23 H AFTER IRRADIATION

Treatment	Fresh weight		QGC	
	mg/bud	% increase over D.F.	μM/g fresh wt.	% increase over D.F.
Dark initial	5.35	67	0.11	85
Dark final	7.95	100	0.13	100
Red (98 kergs cm <sup>-2</sup> )	14.65	184	0.26	276
Far red (845 kergs cm <sup>-2</sup> )	9.85	118	0.17	131
Red-far red (energies as above)	9.19	116	0.19	146
Far red-red (energies as above)	12.12	165	0.23	254

Using the foregoing technique, the presence of KGC in totally etiolated terminal buds was confirmed (0.5-0.8 μM/g fresh weight). On irradiation with 327 kergs cm<sup>-2</sup> of red light, the content of QGC increased markedly during 24 h, while KGC content was not changed during this period (Table 1). When increasing dosages of red light were given, QGC synthesis increased with increasing energy with no obvious saturation-level (Table 2). KGC content, on the other hand, was not increased by irradiances of up to 1,000 kerg cm<sup>-2</sup>. These data, which are representative of several experiments, indicate that low-energy red light causes a marked increase in the synthesis of the quercetin derivative, with no effect on the kaempferol derivative. Evidence that this was indeed a phytochrome effect was obtained by carrying out a red-far red reversibility test (Table 3). It is thought likely that incomplete separation of KGC and QGC using paper chromatography is responsible for the conflict between these findings and those reported earlier<sup>1,2</sup>.

It would thus appear that in 'Alaska' peas, the presence of phytochrome in the far-red absorbing form (*P<sub>FR</sub>*) is essential for appreciable synthesis of the quercetin derivative, but is not required for the synthesis of the kaempferol derivative. The significance of this finding is perhaps heightened by the fact that the two substances, although quite complex, differ only in the presence or absence of a single hydroxyl group (kaempferol is 3,4',5,7-tetrahydroxyflavone; quercetin is 3,3',4',5,7-pentahydroxyflavone). These results, therefore, indicate that *P<sub>FR</sub>* functions, in one of its presumably more remote roles, in some way to determine the hydroxylation pattern of flavonoids. Our findings are in general agreement with the tentative conclusions recently reported by Stafford<sup>7</sup> of an involvement of phytochrome in 3'-hydroxylation of *Sorghum* flavonoids.

### Seed-borne Primary Infection in Downy Mildew, *Sclerospora maydis* (Racib.) Butler

Downy mildew, *Sclerospora maydis* (Racib.) Butler, is a very destructive disease of corn in Indonesia and can wipe out whole fields. In 1964, the disease caused an average 90 per cent infection in Tjiandjur, West Java, causing a total crop failure in that area.

Rutgers<sup>1</sup>, while studying the mode of primary infection, reported that in one of his tests he got 4 diseased seedlings from 5 kernels obtained from diseased plants. In a second test with 50 seeds, only healthy plants were obtained. In another lot of kernels, even after hot water seed treatment at 60° C he got diseased seedlings. However, his investigations were not on an extensive scale and he could not reach any definite conclusion on the mode of primary phase of the transmission of the disease.

Palm<sup>3</sup> reported that oospores are not produced under Java conditions and that the only mode of transmission of the disease was through conidia.

Weeton<sup>2</sup> found out that in *S. philippinensis* the mycelium in badly affected ears could be traced in the cob along the funiculus of attachment in to the undeveloped parts of the abortive kernels and sometimes even in to the seed coat and the endosperm, but not in to the embryo itself.

Gattani<sup>4</sup> reported the presence of hyphae of *S. philippinensis* in the growing points of severely infected plants but did not report on the production of diseased seedlings from kernels obtained from such plants.

The present investigations were undertaken to determine the nature of primary infection of the disease. For this purpose, cobs of 'Metro' variety of corn were obtained from a seriously infected field in Purwokerto, Central Java. The kernels from these cobs were planted in the screen house at Bogor, West Java, and after 5 days of planting, diseased seedlings appeared. The percentage of infection after 5 days of planting was 10, but rose to 36.5 on the ninth day of planting. All the diseased plants produced conidia in the screen house test.

Further tests were made in a well-lit room with closed doors at 26°-29° C and 55 per cent relative humidity. Kernels of 'Metro' variety from plants which had been naturally infected in the seedling stage in the experimental field at Bogor were planted in sterile soil. Infected seedlings showing chlorosis appeared after 5 days. Such chlorotic plants did not produce any conidia while in the room but produced normal conidia in the morning, having been transferred to the outdoor screen house over-night. The percentage of infected seedlings obtained in this test, repeated 3 times, was 20.

In another experiment, plants which showed infection after 5 days were cut at the base to remove all the infected leaves. The new leaves which were later produced again showed the typical disease symptoms, indicating that such plants had systemic infection.

Four- to 9-day-old diseased plants were removed from the pots with intact roots. Such plants were dissected for their growing points. When stained with cotton blue, fungal hyphae could be detected in such growing points.

It would therefore seem that the primary infection of *S. maydis* is caused by fungal mycelium lodged in the embryo of the kernels of severely infected plants.

I thank Dr. M. L. Gattani, Ir. Soenardi and Mr. Ida Njoman Oka for their advice.

## Influence of Carbon Dioxide on the Uptake of Water by Asparagus

Excised shoots of asparagus (*Asparagus officinalis* L.) with cut ends immersed in tap water undergo a marked gain in fresh weight during storage in atmospheres containing more than normal amounts of carbon dioxide<sup>1</sup>. Shoots, 16 cm in length, were stored in chambers at 1.7° C in darkness for one week. Modified atmospheres were obtained and maintained within 1.5 per cent of the desired levels by intermittent flushing with gases from pressure cylinders. When elimination of carbon dioxide was desired the carbon dioxide of respiration was absorbed in dry slaked lime.

The weight gain which was attributed to water uptake coincided with an increase in length. Typical results are shown in Table 1. Levels of oxygen lower than that of air had little effect. A level of carbon dioxide as low as 3 per cent showed some effect and the optimum level for these responses was in the 12-15 per cent range. Uptake of

Table 1. GAIN IN FRESH WEIGHT AND ELONGATION OF EXCISED ASPARAGUS SHOOTS IN RESPONSE TO CARBON-DIOXIDE-ENRICHED ATMOSPHERES

Atmospheric composition (%)		Gain in fresh weight (%)	Elongation (%)
O <sub>2</sub>	CO <sub>2</sub>		
Air (control)	0	8.1	6.2
20.5	0	8.8	6.5
16	0	9.1	6.8
15	15	25.4	17.0
15	30	18.8	12.1

water was not diminished by decapitation of the shoots; no attempt was made to determine changes in length of these shoots.

The increases in length, and in uptake of water, were accompanied by increases in pH of the expressed juice as previously reported by Fife and Frampton<sup>2</sup>, by softening of the tissue as measured by the 'tenderometer', and by apparent decreases in soluble solids. However, the percentages of soluble solids corrected for dilution, assuming the weight gain was due entirely to water uptake, were higher in asparagus exposed to higher levels of carbon dioxide. The information, as well as indications of a higher diffusion pressure deficit within the asparagus treated with carbon dioxide, as measured by a gradient of external osmotic solutions, suggests water uptake based on osmosis.

Carbon dioxide here seems to fulfil the role of a growth factor. Mer and Causton<sup>4</sup> have indicated that carbon dioxide has the ability to promote cell division in the dark. It would appear that carbon dioxide may not only promote cell division but also cell enlargement through water uptake mediated by plasticity of the tissue and changes in osmotic properties. However, it must be realized that the uptake of water by excised plant parts may not be strictly analogous to water uptake by plants with intact roots.

## Water Economy of the Dorcas Gazelle

ALTHOUGH the physiology of the camel, kangaroo-rat, jerboa and various domestic animals of desert regions has been examined in some detail<sup>1,2</sup>, nothing is known of the heat and water relations of that most typical desert mammal, the gazelle. It has occasionally been suggested that gazelles may be able to live indefinitely on dry food without water, like desert rodents, but no experiments have been made to determine if this is true or whether, like camels, they need to drink. For this reason an investigation of the water economy of the Dorcas gazelle, *Gazella dorcas* (L.) is now being pursued here.

Preliminary results indicate clearly that gazelles must drink, even in winter, for they lose weight steadily on dry food when deprived of water. After five days desiccation a maximum of 1.5 l. fresh water can be ingested at one time; and smaller quantities of saline water are taken. With increasing dehydration, body temperature tends to lose homeostasis and there is some degree of hyperthermia, the urine becomes concentrated, faecal pellets smaller and drier and food intake is reduced.

In the Sudan, gazelles appear to inhabit desert and semi-arid regions where some water, fresh or saline, or dew and succulent food are available, even if considerable distances have to be travelled in order to obtain them.

## ENTOMOLOGY

Laying Worker Honey Bee:  
Similarities to the Queen

It is known that in the honey bee community the queen has an influence on the behaviour and the physiology of worker bees<sup>1-4</sup>. It has been shown that the presence of a queen in a group of worker bees inhibits the development of the ovaries in the workers<sup>5</sup>. The workers, showing a special behaviour (retinue behaviour) towards their queen, recognize her by special substances. This recognition leads to a 'queenright behaviour', which in turn influences the development of the ovaries. When we take the queen away from such a group, ovarian development in the workers starts, and may result in the so-called laying workers. It seemed to be an interesting point that only a few bees out of a group reached this final stage and it was supposed<sup>6</sup> that perhaps these bees in turn would have an influence on the other bees.

It has been reported that, in a queenless colony, worker bees can evoke a retinue behaviour in other workers similar to that evoked by the queen<sup>6</sup>.

These considerations induced us to study the laying workers more closely. In 6 experimental cages, each containing 50 newly emerged worker bees, a laying worker taken from a queenless observation hive was introduced. This laying worker could be recognized by a paint mark. The bees were provided with water and a feeder containing a sugar-candy and pollen mixture. At regular intervals, during the renewal of the food and the drinking water, the behaviour of the workers towards the marked bee was studied. In all cases the laying worker evoked a distinct retinue behaviour in the workers.

When after 14 days the bees were killed and examined for ovarian development, the cages with a laying worker showed an inhibition of ovarian development in comparison with controls (Table 1).

Laying worker added to the cage		Controls	
Cage No.	Ovarial development (%)	Cage No.	Ovarial development (%)
1	13.0	1	25.1
2	16.9	2	27.0
3	17.6	3	27.6
4	19.9	4	28.0
5	20.0	5	30.3
6	25.2*	6	30.8
mean	18.6	mean	28.1

\* Laying worker died after 4 days.

In a second experiment we compared the inhibitory action of an extract of bees with highly developed ovaries with an extract of bees with undeveloped ones. For this purpose the ovaries of bees of a queenless group were examined. After division into an undeveloped, a poorly and medium developed, and a highly developed group, the first and the last group of bees were extracted in acetone by Soxhlet extraction for 6 hours. Fifty bees were used for each of the extracts.

Extracted dead young worker bees were impregnated with these extracts. A bee impregnated with the 'highly developed' extract was placed in each of 6 cages containing 50 young bees and a bee impregnated with the 'undeveloped' extract in each of 6 control cages. Every 2 days we removed the impregnated object and replaced it with a new one.

At the moment of removal of the impregnated bees observations were made about retinue behaviour. In all cases the 'highly developed' extract evoked retinue behaviour, whereas this was never observed in the control cages.

After 14 days the bees were killed and the ovarian development was determined. Table 2 shows that the 'highly developed' extract inhibited ovarian development.

Table 2

Extract of bees with highly developed ovaries		Extract of bees with undeveloped ovaries	
Cage No.	Ovarial development (%)	Cage No.	Ovarial development (%)
1	17.1	1	37.8

6	9.6	6	34.2
mean	13.6	mean	33.0

Apart from the production of eggs a laying worker obviously resembles the queen in releasing retinue behaviour and in inhibiting ovarian development in young bees under experimental conditions. Just as in the queen, this influence of the laying worker is based on the production of substances that are perceived by the other bees.

Metabolic Effects of the Corpus Allatum  
Hormone in the Desert Locust, *Schistocerca gregaria*

SOME thirty years ago, Wigglesworth<sup>1</sup> first demonstrated that yolk deposition in insect oocytes is controlled by the corpus allatum hormone. Since then, the hormonal control of vitellogenesis has been complicated by some experiments, which suggests that the corpus allatum hormone also has metabolic effects. Allatectomy leads to the accumulation of lipid and the hypertrophy of the fat body in a number of insects<sup>2-4</sup>. From such evidence, Pfeiffer<sup>5</sup> advanced the hypothesis that the corpus allatum controls vitellogenesis by releasing a 'metabolic hormone' that in some way regulates the mobilization of precursor materials from the fat body. This hypothesis has always suffered from the serious objection that ovariectomy does not lead to the expected accumulation of yolk precursor materials in the fat body<sup>2,4</sup>.

A second hypothesis has been put forward by Doane<sup>6</sup>, based on her observations of the hypertrophied fat body of female-sterile mutants of *Drosophila melanogaster*. In such mutants, the corpus allatum is normal in function, since wild-type ovaries implanted into mutant female flies develop eggs normally; the lethality in the mutant forms resides autonomously in the ovaries themselves. Doane therefore suggested: (a) that an 'ovarian hormone' is released by active ovaries in a normal fly, the function of the hormone being to regulate the utilization of stored lipids in the fat body; (b) that the action of the ovarian hormone on the fat body is independent of any analogous action of the metabolic hormone of Pfeiffer, although its release may be indirectly controlled by the gonadotrophic activity of the corpus allatum.

A fresh approach to this problem was attempted when preliminary observations indicated that allatectomized male desert locusts were inactive.

An electron microscope study of the fat body of allatectomized male desert locusts has shown that large deposits of glycogen and lipid accumulate in the fat body. The accumulation of lipid was confirmed by chloroform-extraction of whole locusts. Implantation of active corpora allata into previously allatectomized locusts alleviated this condition.

Spontaneous locomotor activity of adult male locusts was determined by the method of Brown and Unwin<sup>7</sup>. It was found that after allatectomy there was persistent

inactivity of operated locusts, however long they survived. Implantation of active corpora allata led to the resumption of the normal, high level of locomotor activity. Extirpation of the testis and accessory reproductive glands, on the other hand, had no effect either on spontaneous locomotor activity or on glycogen and lipid utilization.

The hypothesis is therefore advanced that the corpus allatum hormone regulates the intensity of locomotor activity by a direct effect on the central nervous system. Since fat and glycogen form the chief energy reserves of locusts<sup>1</sup>, it is suggested that the accumulation of these substances after allatectomy is due to the persistent inactivity of the operated insects.

I thank Sir Vincent Wigglesworth for facilities and advice and the Uganda Government for a research grant.

## MICROBIOLOGY

### *Salmonella* in Bird Faeces

THE contamination of our rivers and beaches with bacteria related to *Salmonella*, caused by the disposal of domestic sewage, is well known. Domestic sewage, collected in the main drainage of the city of Hamburg, has been continually tested for *Salmonella* during the past twenty years. *Salmonella* occurs at a density equivalent to 5,000 organisms in 1,000 ml. of sewage.

After flowing into the Elbe, these organisms are dispersed, but survive, so that some 50–100 organisms can be found in 1,000 ml. of river water.

Steiniger<sup>1</sup> concluded, from his examination of faecal material from birds, that possibly these animals are the origin of the wide spread of *Salmonella* in surface water. In other words, it may not be sewage disposal that contaminates the rivers and beaches; there may exist a sort of *Salmonella* saprophytism in the gut of seabirds, forming an important factor in the spread of *Salmonella* in our environment.

We collected more than 1,000 samples of faecal material from gulls in the area of the biggest sewage disposal works of Hamburg, on bridges and pontoons in the port of Hamburg, and in the streets of the city. 78 per cent of the samples collected at the sewage disposal works were positive for *Salmonella* as were 66 per cent of the samples collected in the port and 28 per cent of the samples collected in the city. The most frequently isolated species, as in water samples of the Hamburg sewers, was *S. paratyphi* B. The faeces of gulls collected in those regions which were free from the influence of sewage never contained *Salmonellae*. As, on the other hand, the faeces of birds collected near the sewage disposal works were positive, one must conclude that the presence of *Salmonella* organisms in these birds is related to a source of infection, and does not present *visu generis* the normal bacterial flora in the gut of birds. Furthermore, this conclusion is confirmed by the range of species isolated, which exactly corresponds to the species isolated from the water of Hamburg rivers. The most frequently isolated species was *S. paratyphi* B, followed in order of frequency by *S. typhimurium*, *S. manchester*, *S. montevideo*, *S. infantis*, *S.*

*senftenberg*, *S. anatum*, *S. stanley*, *S. newport*, *S. braenderup*, *S. san diego*, *S. dubisburg*, *S. muenchen*, *S. blockley*, *S. bovis morbillicans*, and *S. panama*.

In examining the faecal material of other birds, the most striking fact was the great proportion of pigeons (30 per cent) and ducks (16 per cent) which contained *Salmonella*, while the faecal matters of thrushes (0.15 per cent) and sparrows (0.2 per cent) only occasionally showed a positive result. Birds kept indoors, such as canaries or parrots, were always negative for *Salmonella*. It is thus clear that a lack of source of infection results in a lack of *Salmonella* in the faeces. Faeces of pigeons from Tanganyika and Venice were *Salmonella* positive in 30 and 29 per cent of cases respectively. While the faeces of gulls collected in Hamburg showed a preponderance of the species *S. paratyphi* B, samples of pigeons and ducks frequently contained *S. typhimurium*: samples of pigeon-dirt collected in Hamburg 80 per cent, samples of duck-dirt 80 per cent, samples of foreign pigeon-dirt 90 per cent. The other species isolated were, in order of frequency: *S. manchester*, *S. paratyphi* B, *S. anatum*, *S. newport*, *S. panama*, *S. makumira*. This last mentioned genus was a new species with the antigen-formula 4, 12: ex: 1, 7, first isolated from the faeces of an African pigeon (Rohde and Müller<sup>2</sup>).

The occurrence of *S. paratyphi* B in considerable amounts in the faeces of healthy city-birds leads to the conclusion that this organism, which is important for the epidemiology of man, has a wide distribution. On the other hand, *S. typhi* could not be isolated in any of 3,000 faecal samples from different native birds.

Consequently there must be an epidemiological difference between these two species, although the clinical picture of the infectious disease of man, expressed as septicæmia, is the same.

### Transfer of RNA Extracts from Immune Donor Spleen Cells to *Shigella*-tolerant Recipient Mice

INJECTION of relatively large quantities of non-living antigens into either neonatal or adult animals often results in the establishment of immunological tolerance characterized by specific suppression of antibody formation on subsequent challenge immunization<sup>1</sup>. Immune tolerance to bacteria has been demonstrated most often in mice injected with polysaccharide antigen derived from pneumococci<sup>2,3</sup>. Somewhat similar states of immunological tolerance to antigens derived from other micro-organisms have also been investigated. For example, tolerance to *Shigella paradyserteriae* antigens has been observed in mice after a single administration of a relatively large concentration of soluble *Shigella* antigen within 12–24 h after birth<sup>4</sup>. The resulting tolerance persisted for at least 8–12 weeks, depending on the dose and route of antigen administered at birth. Tolerance to *Shigella* has been terminated in unresponsive mice by transfer of spleen cell suspensions from normal or *Shigella* immune donors<sup>5</sup>. Administration of hyperimmune anti-*Shigella* serum to tolerant mice, however, has not restored agglutinin forming ability<sup>6</sup>.

There have been several recent reports concerning acquisition of antibody formation by non-immune normal animals or cell suspensions following treatment with RNA extracted from immune donors<sup>7–11</sup>. Since it is not known whether tolerance to an antigen may be due to selective removal of possible 'clones' of cells potentially

capable of forming antibody<sup>12</sup>, or due to direct suppression of antibody synthesis by 'excess' antigen in direct contact with lymphoid cells, it was thought of interest to determine whether or not RNA-rich extracts from immune donor lymphoid cells could restore immune responsiveness in specifically tolerant animals. This report is concerned with agglutinin formation to *Shigella* antigen in *Shigella*-tolerant mice treated with RNA extracts from *Shigella*-immune or normal donor mice.

Young adult NIH albino mice 8-10 weeks of age were used as donors for this study. They were injected 7-10 days before being killed with 20-50 µg *Shigella*-soluble antigen (SSA) obtained by trypsin digestion of an alcohol-killed suspension of *Shigella* organisms as described previously<sup>4-6</sup>. Groups of 10 or more immunized donor mice, as well as non-immune control donor mice, were bled from the retro-orbital plexus to obtain blood for determination of serum agglutinins to *Shigella*. The mice were then killed and spleens removed and immediately frozen with dry ice. The frozen spleens were homogenized with a 'Teflon'-tipped tissue homogenizer at 0°C, and RNA was extracted by the cold phenol method<sup>13,14</sup>. The extracted RNA was standardized by the orcinol reaction and by ultra-violet absorption so that 1.0 ml. contained 300-400 µg RNA. There was no serologically detectable antigen or antibody in the extracts.

The RNA-rich extracts from *Shigella*-immune donors were administered intraperitoneally in 1.0-ml. quantities to groups of 6-8-week-old recipient NIH mice which had not been treated previously or had been injected at birth with sufficient SSA to induce immune tolerance to the antigen. Similar groups of recipients were injected with 1.0-ml. quantities of RNA extracts prepared from the normal non-immune control donor mice. A third group of normal or *Shigella*-tolerant control recipients was injected with saline instead of RNA preparations. All recipients, in all groups, were then challenged with an intraperitoneal injection of 0.5 ml. of SSA containing 20 µg N to test their ability to form anti-*Shigella* agglutinins. Blood samples were obtained from the retro-orbital plexus from each recipient at close periodic intervals for two to three weeks and the resulting serum specimens tested for anti-*Shigella* agglutinins by standard tube agglutination procedures.

Anti-*Shigella* agglutinin titres of normal and *Shigella*-tolerant recipient mice receiving RNA and a challenge injection with *Shigella* antigen are indicated in Table 1. Most non-tolerant control mice, receiving saline or RNA from non-immune donors before challenge immunization with SSA, responded with mean peak agglutinin titres of 1:300 or greater. Nearly all mice which had received a tolerance-inducing injection of SSA at birth and saline only before *Shigella* challenge had post-challenge anti-*Shigella* titres of 1:40 or less, indicative of continued immunological tolerance. Transfer of RNA from non-immune donors similarly had no effect on tolerance. *Shigella*-tolerant recipient mice injected with RNA obtained from the immune donor mice also had markedly depressed anti-*Shigella* agglutinin titres when challenged with *Shigella* antigen at 6-8 weeks of life. Control non-tolerant mice receiving RNA from immune donors often responded with higher agglutinin titres than control mice receiving saline only or RNA from non-immune donors

Table 1. ANTI-*Shigella* AGGLUTININ TITRES OF NORMAL AND *Shigella*-TOLERANT RECIPIENT MICE AFTER TRANSFER OF RNA FROM NORMAL OR *Shigella*-IMMUNE DONOR MICE AND CHALLENGED WITH *Shigella* ANTIGEN\*

RNA donors	Normal		<i>Shigella</i> -tolerant†	
	No. positive‡	Mean peak titres	No. positive	Mean peak titres
None (saline)	18/21	1:372	5/23	1:88
Normal	17/19	1:507	2/17	1:27
<i>Shigella</i> -immune§	20/23	1:400	3/19	1:33

\* All recipients injected with *Shigella*-soluble antigen (20 µg N) at 6-8 weeks of age.

† Tolerant mice injected at birth with *Shigella* antigen.

‡ Number of mice with peak post-challenge titre of 1:64 or more.

§ Immunized 7-10 days before killing by i.p. inoculation of *Shigella* antigen.

Table 2. ANTI-*Shigella* AGGLUTININ TITRES OF MICE RECEIVING RNA FROM NORMAL OR *Shigella*-IMMUNE DONORS AND EITHER UNCHALLENGED OR CHALLENGED WITH *Shigella* ANTIGEN\*

RNA donors	Recipient mice	Challenge immunization	
		None	<i>Shigella</i> antigen†
Normal	Normal	<1:10	1:343
<i>Shigella</i> -immune‡	Normal	<1:10	1:23
	Normal	1:63	1:376
	<i>Shigella</i> -tolerant‡	1:20	1:34

\* Mean peak titres of at least 10 mice per group.

† Recipients challenged at 6-8 weeks of life with *Shigella* antigen (intraperitoneal) (20 µg N).

‡ Tolerant recipients injected at birth with *Shigella* antigen.

§ Immune donors injected with *Shigella* 7-10 days before killing.

immediately before challenge immunization. Administration of RNA extracts from immune donors to normal mice not receiving *Shigella* immunization also resulted in some level of agglutinin formation (Table 2), suggesting transfer of either *Shigella* antigens or a possible agglutinin-forming mechanism to recipient mice.

These results indicate that RNA-rich extracts from *Shigella*-immune donor mice are not capable of restoring specific agglutinin forming capacity to *Shigella*-tolerant recipient mice under the conditions of the investigation. This is in contrast to previous results in which it was found that RNA-rich subcellular fractions from *Shigella*-immune donors were capable of inducing a measurable degree of immunity in either normal or X-irradiated non-immune recipient animals<sup>15,16</sup>. The results presented here are also in contrast with the findings by Feldman *et al.*<sup>17</sup> that nucleic acid preparations from normal rabbit spleens are capable of specifically restoring the immune response to human serum albumin in rabbits rendered tolerant to that antigen following treatment with 6-mercaptopurine.

The inactivation of RNA by serum or tissue RNases in recipient animals in this study may be an important factor in the failure of restoration of immune competence in tolerant animals. However, similar levels of RNase should also be present in normal animals injected with RNA. Transfer of less purified RNA preparations, especially ribonucleoprotein extracts or subcellular fractions, might be more effective agents for biological restoration of immunity since they are less likely to be inactivated by RNase<sup>18</sup>. They are also more likely to contain persisting antigenic determinants and thus actively stimulate agglutinin formation. However, if tolerance is due to persistence of 'excess' antigen, presumably at an intracellular site, it is unlikely that administration of nucleic acid extracts containing additional antigen would restore agglutinin formation in a tolerant recipient.

This investigation was supported in part by grants from the U.S. National Science Foundation (GB 1188, G-19581).

## FORTHCOMING EVENTS

Wednesday, September 22

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at the School of Pharmacy, University of London, Brunswick Square, London, W.C.1), at 9.30 a.m.—Symposium on "Food Science Research in the United Kingdom".

SOCIETY OF ENVIRONMENTAL ENGINEERS (In the Mechanical Engineering Department, Imperial College, Exhibition Road, London, S.W.7), at 6 p.m.—Squadron Leader L. F. Gillard: "The Correlation of Service Defects and Laboratory Experience".

Thursday, September 23

BRITISH INTERPLANETARY SOCIETY (In the Large Physics Theatre, University College, Gower Street, London, W.C.1), from 10 a.m. to 4.30 p.m.—Symposium on "Modern Trends in Space Physics".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR LECTURER (honours graduate with good teaching experience) IN GRAP HUBBARDY—The Principal, Essex Institute of Agriculture, Writtle, Chelmsford, Essex (September 23).

DEPUTY DIRECTOR (Research) (with considerable experience of biological research, particularly in the field of ecology, and its applications, and experience of scientific administration) OF THE NATURAL CONSERVANCY at the London Headquarters, Belgrave Square, S.W.1.—The Natural Environment Research Council, Establishments Division, State House, High Holborn, London, W.C.1 (September 24).

HEAD (with high academic qualifications with appropriate experience in industry, research and/or teaching at university level) OF THE DEPARTMENT OF MATHEMATICS AND PHYSICS, Grade IV, College of Technology, Sheffield—The Director of Education, P.O. Box 67, Sheffield (September 24).

LECTURER OR ASSISTANT LECTURER in one of the following: (a) SOCIOLOGY or (b) SOCIAL ADMINISTRATION—The Registrar, The University, Keele, Staffs (September 24).

SENIOR RESEARCH ASSOCIATE (with a good honours degree in engineering or physics and some research experience) IN THE DEPARTMENT OF MECHANICAL ENGINEERING, for work in the fields of mechanisms and gyroscopes—Prof. L. Maunders, Department of Mechanical Engineering, The University, Newcastle upon Tyne (September 24).

SENIOR RESEARCH FELLOW (graduate in science with substantial post-graduate experimental research experience in the study of ionization phenomena in gases), to hold a responsible position in a group engaged in the study of ionization phenomena in low-pressure flames—The Secretary, Department of Physics, The University, Bedford (September 24).

RESEARCH ASSISTANT (with a good honours degree, preferably with some training or specialization in marine biology) IN THE MARINE SCIENCE LABORATORIES to carry out a programme on zooplankton succession—The Registrar, University College of North Wales, Bangor, North Wales (September 25).

TEMPORARY LECTURER/ASSISTANT LECTURER (able to lecture on North America) IN GEOGRAPHY—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (September 25).

SENIOR RESEARCH FELLOW (graduate in science or engineering) IN THE DEPARTMENT OF EDUCATION to be concerned primarily with the devising of a course in programmed learning form for the Higher National Certificate in Electrical and Electronic Engineering—The Academic Registrar, Brunel College, Woodlands Avenue, London, W.3 (September 26).

RESEARCH ASSISTANT IN THE SCHOOL OF PHYSICS to work in the field of experimental geophysics or solid state physics—The Registrar, The University, Newcastle upon Tyne (September 27).

POSTDOCTORAL FELLOW (with experience in plasma physics, microwave techniques or electromagnetic theory and use of a computer) in a plasma physics group which is studying the scattering of microwaves by various plasma configurations—The Registrar, University College of Wales, Aberystwyth (September 28).

RESEARCH STUDENT (suitably qualified electronic or electrical engineer, or physicist interested in research in the field of digital frequency modulation) IN THE DEPARTMENT OF ELECTRONICS—Prof. G. D. Sims, University of Southampton, Southampton (September 30).

LECTURERS (medical practitioners registered with the South African Medical and Dental Council with special training and interest in morbid anatomy and histopathology) IN THE DEPARTMENT OF PATHOLOGY AND MICROBIOLOGY, University of the Witwatersrand, Johannesburg, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa, September 30).

SENIOR LECTURER AND LECTURER (with an honours degree in mathematics and preferably a higher degree and some experience of teaching and research) IN MATHEMATICS; a LECTURER (with a Ph.D. degree and some post-doctoral research experience) IN PHYSICAL CHEMISTRY; and a LECTURER (with a Ph.D. degree and some post-doctoral research experience) IN PHYSICAL CHEMISTRY (Theoretical) at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (September 30).

SENIOR TUTOR/TUTOR IN THE DEPARTMENT OF ZOOLOGY, School of Biological Sciences, University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

ASSOCIATE PROFESSOR IN THE DEPARTMENT OF GEOLOGY AND GEOPHYSICS, University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 1).

LECTURER OR ASSISTANT LECTURER IN THE DEPARTMENT OF ELECTRONIC COMPUTING—The Secretary, The University, Aberdeen (October 1).

LECTURER OR SENIOR LECTURER IN INORGANIC AND PHYSICAL CHEMISTRY, or in ORGANIC CHEMISTRY at the University of New England, Armidale, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 4).

LECTURER OR ASSISTANT LECTURER IN PHYSICS at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 8).

ENTOMOLOGIST (with at least a B.Sc. (Agriculture), or equivalent qualification) IN THE DEPARTMENT OF AGRICULTURE, New South Wales, Australia, to carry out research on insect pests affecting crops—The New South Wales Government Office, 56 Strand, London, W.C.2 (October 6).

READER IN BIOCHEMISTRY at Guy's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 8).

ASSISTANT EXPERIMENTAL OFFICER (graduate in a biological science, pure or applied, with an interest in field work) IN THE NEMATODE DEPARTMENT, to assist in work on nematodes injurious to cereals and their control—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/80 (October 15).

CHAIR OF PHARMACOLOGY AT THE UNIVERSITY OF SINGAPORE—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 15).

LECTURER/SENIOR LECTURER (with research experience on some branch of either pure or applied mathematics) IN MATHEMATICS at the University of New England, Armidale, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 15).

RESEARCH ASSISTANT (preferably with some experience with piezoelectric materials, wave propagation, or an allied subject) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, to design and conduct experimental investigations to clarify the principles of electromechanical filters for operation at megacycle frequencies—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (October 15).

SENIOR LECTURER IN BIOCHEMISTRY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 15).

TEACHING FELLOW (with an honours degree in geophysics or physics or equivalent qualifications) IN THE SCHOOL OF APPLIED GEOLOGY, University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 15).

THIRD CHAIR OF MEDICINE at the University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 15).

LECTURER IN THE DEPARTMENT OF ORGANIC CHEMISTRY, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 16).

CHAIR OF VETERINARY SURGERY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 25).

ASSISTANT PROFESSOR IN BIOCHEMISTRY—Prof. G. H. Connell, Chairman, Department of Biochemistry, University of Toronto, Toronto 5, Ontario, Canada (October 30).

SENIOR LECTURER (with general experience in zoology and special interests and qualifications in one or more of the major divisions of zoological science) IN ZOOLOGY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

LECTURER (with an honours degree or equivalent) IN THE DEPARTMENT OF PHILOSOPHY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 1).

SENIOR LECTURER IN THE SCHOOL OF BOTANY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 4).

UNIVERSITY LECTURER OR UNIVERSITY DEMONSTRATOR IN THE DEPARTMENT OF PHARMACOLOGY—T. D. Kellaway, Department of Pathology, The University, Tennis Court Road, Cambridge (November 4).

LECTURER (with a distinguished academic record in ceramic engineering, chemical engineering or mining engineering, and preferably several years professional experience) IN CERAMIC ENGINEERING at the University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 30).

READER IN THE DEPARTMENT OF MECHANICAL ENGINEERING, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 30).

ASSISTANT PROFESSOR OF SOCIAL ANTHROPOLOGY—Dr. R. K. Crook, Dalhousie University, Halifax, Nova Scotia, Canada.

CHAIR OF BUILDING SCIENCES IN THE SCHOOL OF ARCHITECTURE—The Registrar, University of Strathclyde, George Street, Glasgow, G.1.

GRADUATE HISTOLOGIST (with an interest in mammalian histology and some knowledge of histological technique) to amplify and extend a very important and promising project—The Director, Tobacco Research Council Laboratories, Harlow Hill, Harrogate, Yorkshire.

LABORATORY TECHNICIAN, Grade II, IN THE DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY, chiefly for administration, including ordering of stock and supervision of junior staff, in a series of laboratories concerned with chemistry, biochemistry and physiology—The Assistant Bursar (Personnel), University of Reading, Reading, Berkshire.

LECTURER IN BOTANY; a LECTURER IN CHEMISTRY; and a LECTURER IN PHYSICS at the University of Basildon, Basildon and Procter and Swadlow—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

LECTURER IN INORGANIC CHEMISTRY—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

LECTURER OR ASSISTANT LECTURER IN PHYSICS at the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

LECTURER OR ASSISTANT LECTURER IN THE DEPARTMENT OF PHYSICS, University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

LECTURER (preferably with an interest in relativity or statistics) IN MATHEMATICS—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

LECTURER (with a number of years' post-doctoral experience, ideally in the fields of crystallography, deformation, or electron microscopy, together with suitable teaching experience) IN THE DEPARTMENT OF METALLURGY in the field of physical metallurgy—Prof. J. G. Ball, Metallurgy Department, Imperial College of Science and Technology, London, S.W.7.

LECTURERS AND ASSISTANT LECTURERS IN MATHEMATICS, COMPUTING AND STATISTICS—The Academic Registrar, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

POSTDOCTORAL RESEARCH FELLOW IN THE PHYSICS DEPARTMENT to work on an investigation into solid state theory under the direction of Prof. K. W. H. Stevens—The Registrar, The University, Nottingham.

POSTGRADUATE RESEARCH ASSISTANT (with a good degree in chemistry or physics) IN THE DEPARTMENT OF CHEMISTRY, for work in collaboration with Dr. K. B. Jennings on the structural significance of metastable ions in the

mass spectra of organic compounds—The Registrar, The University, Sheffield, 10.

PROFESSOR (with a wide experience of education and a particular interest in the field of university education where the emphasis is on technology and applied science) OF EDUCATION—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 45/G.

RESEARCH ASSISTANT (with a good honours degree in pharmacy, microbiology or biochemistry) IN PHARMACOLOGICAL MICROBIOLOGY, to work upon a project forming part of a major work in the field of resistance of micro-organisms to antimicrobial agents—The Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7, quoting Ref. OST 65/86.

RESEARCH ASSOCIATE OR RESEARCH STUDENT (young chemist, physicist or metallurgist, with at least an honours degree or its equivalent) IN THE METALLURGY DEPARTMENT, to work on stress corrosion in high carbon steel wire (the project will involve advanced electron microscopy as well as electro-chemistry)—Dr. J. D. Ghoshal, Metallurgy Department, The University of Newcastle upon Tyne, Newcastle upon Tyne, 1.

SENIOR SCIENTIFIC OFFICER (young graduate physicist or physical chemist, preferably with several years' research experience) IN THE PHYSICS LABORATORY for work mainly concerned with an important research project supported by an earmarked grant from the Ministry of Technology—The Secretary, British Baking Industries Research Association, Chocleywood, Rickmansworth, Hertfordshire.

TECHNICIAN (with some background of laboratory work) IN THE DEPARTMENT OF PHYSICS, to assist in a programme of research on the growth of certain semiconducting crystals—The Registrar, University College of North Wales, Bangor, North Wales.

## UNIVERSITY EXPANSION IN BRITAIN

THE fifth report from the Estimates Committee for the session 1964-65\*, dealing with grants to universities and colleges, is a document of outstanding public importance. Although the publication of the report within a few days of the announcement of the Government's decision to curtail capital expenditure has focused attention, as in the debate on education in the House of Commons on August 3, on the last two paragraphs of the report, its significance is much deeper and more permanent. It presents a penetrating and thorough examination of the whole working of the University Grants Committee system in the context of the present structure of Government in Britain. The voluminous evidence throws light on the nature of the particular problems which arise in the development of new universities and the change in status of the colleges of advanced technology. Taken with the memoranda from the University Grants Committee itself, the Committee of Vice-Chancellors and Principals, the Treasury, the Department of Scientific and Industrial Research, and the Secretary of State for Education and Science, for example, it is likely to constitute for years to come a standard reference on the functioning of the whole system.

Probably the key-passage in the report is the paragraph in the introduction which notes that since the Select Committee on Estimates enquired into university grants in its fifth report for the Session 1951-52, the grant-in-aid to universities has risen from £23.5 million to £132.9 million for 1964-65; for 1965-66, when it will include the colleges of advanced technology, it is expected to reach £193 million. This increase was a main factor which led the Estimates Committee to undertake a fresh examination. However, in view of the debate on August 3 and of what was said in the House of Lords on August 4, it may be as well to dispose first of the question of the proposed restriction of the building programme. On August 4, the Minister of State for Education and Science, Lord Bowden, told the House of Lords that university building projects for which contracts had not yet been signed would be postponed for six months except in development districts and areas of high employment. The Secretary of State for Education and Science, he said, would consider urgently, in consultation with the University Grants Committee, how best to minimize the effects of this decision on the growth in student numbers. Since then, in replying to questions, Lord Bowden has stated that the restriction was being applied to universities rather than to schools, and that it would fall in some measure on technical colleges. In the House of Commons on August 3 the Minister of State, Department of Education and Science, confirmed that the minor works programme for schools would go forward this year as planned and that the school building programmes to the middle of 1967-68 would stand as previously announced. In replying on the debate, Mr. R. E. Prentice made it clear that capital improvements in the education service as a whole, except for schools, would be postponed for six months.

Mr. Prentice admitted that this was a serious matter for the universities and, while declining to estimate the

total cost to the education service of these measures, appeared to accept Dr. J. Bray's suggestion that the number of students admitted might be decreased by 10,000. He was, however, clearly hoping that the universities might find means of offsetting this, for example, by planning the more intensive use of accommodation and equipment. Concerning the technical colleges, for which the building programme had risen from £17 million in 1964-65 to £26 million in 1965-66, he thought the effect would be slight, and although he admitted that the postponement would be a disappointment to the colleges of education he told the House that entrants to the training colleges in September 1965 were expected to reach 28,000 compared with 24,000 in 1964, giving a student population of 70,000; the target of 122,000 places by 1973 remained.

Sir Edward Boyle was doubtful whether, in fact, this figure was now likely to be achieved, but he thought Dr. Bray was unduly pessimistic as to the fall in the number of university students and he did not think that it would be any answer to increase the number of students studying at home. Mr. Prentice assured him that the basic assumptions of educational policy, which visualized expenditure on education as rising annually in real terms at a little less than 6 per cent per annum, had not been changed in any way. Sir Edward also referred to the negotiations in 1964 between the Government and the universities through the University Grants Committee: these eventually led the Committee to agree that the universities should attempt to achieve the short-term expansion target of the Robbins Report for an additional capital expenditure of about £40 million instead of the £80 million originally regarded as a minimum.

This debate took place in the light not only of the Government's announcement about postponement of capital expenditure but also of the Estimate Committee's reference to evidence of widespread disquiet about the relation between the present estimates of grants to universities and the student numbers expected as a result of the Robbins Report. The universities were unanimous in their evidence that the scope of capital grants was insufficient to provide properly for the rise in numbers after 1967. While the University Grants Committee agreed that the present scale of grants would enable the targets set for 1967 to be attained, it confirmed the view of the universities that the provisional allocation for the following years would not support or sustain those numbers. The Department of Education and Science expressed the opinion that in the past the numbers of students had in practice been almost exactly those for which the capital programme was supposed to provide. In May the chairman of the University Grants Committee had already expressed the opinion that, without addition to these provisional figures, students would be very cramped and crowded.

Accordingly, the Estimates Committee records in the fifth report its fear that a conflict between desired numbers and desirable standards may be inevitable and that pressures within the universities may undermine the plan of the University Grants Committee to use the period 1967-72 to repair obsolescence in buildings and equipment. Its enquiry did not extend to the possibility of a more intensive use of university buildings and facilities by such

\* Fifth Report from the Estimates Committee together with the Minutes of the Evidence taken before Sub-Committee B and Appendices, Session 1964-65—Grants to Universities and Colleges. Pp. xiv+1+288. (London: H.M.S.O.) 28s. net.

measures as changes in the university terms, nor was it for the Committee to recommend a reduction in student numbers. The report is emphatic, however, that if the target set by the Robbins Report is to be achieved without prejudice to accepted standards of university education, a further large increase in capital grants is unavoidable.

Neither the target of numbers nor accepted standards are necessarily sacrosanct. For all the Robbins Report, it should be remembered that that target is still regarded by some responsible opinion as too high, at least so far as universities are concerned. Nor are questions of standards to be considered without reference to that of the whole purpose of university, as distinct from other forms of higher education. But while the Estimates Committee at this point rightly reminds us that we have not yet willed the means for the end we have accepted, the pertinence of the Report in this connexion lies in its further reminder that by failing to do so—still more by the six-month postponement now proposed—we are in danger of gross waste of public resources.

Appended to the report is a memorandum from the University of Kent, which makes this point very effectively by citing specific instances of loss of efficiency through inability to commit capital except at short range. This effect of uncertainty on efficiency was confirmed in evidence from Sir Robert Matthew, a past president of the Royal Institute of British Architects. Such inefficiency and even waste is accentuated by the postponement of building projects now proposed by the Government, and independent of any effect on the eventual achievement of the target set for university expansion, the one certain result is considerable waste of public money. If achieved at all, the target will require even greater financial expenditure and possibly also more skilled manpower.

It is entirely relevant to the Government's action to point out that the whole purpose of this enquiry by the Estimates Committee into the greatly increased expenditure on the universities, which over the past decade has risen more than six-fold, was to satisfy Parliament that these large sums were wisely expended and that the Nation was obtaining a reasonable return on its investment. A start-and-stop policy makes nonsense of such recommendations as the Estimates Committee was able to make or of the steps which the University Grants Committee or the universities have already taken. Furthermore, it accentuates a major and inherent defect of the quinquennial system—that of the transition from one quinquennium to the next, which imposes a stress which can amount almost to a standstill. The Estimates Committee considered, in fact, that for the last two years of a quinquennium the consequent uncertainties already had a serious and depressing effect within universities, particularly with teams of research workers. This, of course, is in accordance with the observations and advice of the Plowden Committee on the Control of Public Expenditure, which unreservedly condemned a start-and-stop policy so far as research was concerned.

In the scientific field, a start-and-stop policy also accentuates a difficulty which is already acute in regard to equipment. The rate of obsolescence is rising rapidly and such equipment is also liable to a 5 per cent per annum rise in costs solely on the factor of increasing complexity. Moreover, the existing practice is criticized both by the Treasury and the universities. On a rising building programme it is difficult to estimate how much equipment will be required for a particular building or a particular year, and the rule governing capital grants favours those obtaining grants in contrast to those who have to re-equip

out of recurrent grant. The Estimates Committee recognizes that this is a serious problem and it recommends that the University Grants Committee should undertake a survey, on the lines of the obsolescent buildings schedule, of at least all major scientific departments to determine the degree of obsolescence in equipment. Moreover, it suggests that the Treasury Working Party which is considering budgetary control should examine, as a matter of urgency, the idea of an annual recurrent capital grant for bringing up to standard some of the worst equipment in the older buildings. When a reasonable standard has been achieved, the possibility should be considered of a process of amortization, writing off and depreciation of equipment over a period of time.

Otherwise this report of the Estimates Committee does not bear greatly on the difficulties into which the Government's latest decision has put the universities. It attempted to discover ways of getting value for money and also ways in which the structure of Government could be altered to provide greater efficiency and greater incentives towards economy in the universities. By and large, the universities and the University Grants Committee come out well from this examination, as does the Treasury, but that can scarcely be said for the Department of Education and Science. The evidence, however, indicates a response to its efforts to enlist the universities both in increased co-operation with the University Grants Committee and in individual and collective efforts to demonstrate publicly that they are making the best use of public money and the facilities they enjoy.

It might be noted here that the Estimates Committee fully supports the recommendation of the Robbins Committee that the level of fees should be raised from the present 10 per cent of the average cost of their education to 20 per cent. Treasury evidence indicated that a Government which was prepared to halt building projects for six months was not ready to take a step which the universities themselves would seem to welcome and which would also help to bring home to students that payment of fees does not meet costs. In the Estimates Committee's view, raising fees to a fairer level would have the advantages of involving local authorities to a greater extent in university education and also recouping a higher proportion of the cost of education from overseas students. The present rules should be modified to prevent the increased contribution causing parental hardship.

Evidence was taken from the Department of Scientific and Industrial Research on the provision of grants to universities for research and equipment for research, which in 1964-65 amounted to £8 million. On this the Estimates Committee makes two comments only. Such equipment is now consigned completely to the university concerned because the Department does not want the responsibility of dealing with obsolete equipment. The Estimates Committee makes the sensible comment that while this may be generally sound, on occasion the conclusions of a particular piece of research or the break-up of a special research team may leave a university with serviceable equipment for which there is no definite use. Secondly, while the Department of Scientific and Industrial Research thought it important that as soon as possible research projects should be fully assimilated by the university into its control, such transfer occurs at the end of the quinquennium. The Estimates Committee thinks that this practice might be a deterrent and suggests that universities should be encouraged to take over projects at any time during the quinquennium, even with the use of private funds.

For the remainder, the report is concerned with the University Grants Committee and its functioning rather than with the actual expenditure of the grant-in-aid of universities. The earlier controversy over the principle of academic freedom in this matter is not reopened. It is accepted that the system of allocation and control of the various grants to universities is intended: (1) to give the universities, as institutions responsible for their own academic planning, management and development, an assurance of the amount of Government support they would obtain; (2) to keep university development responsive to national needs, while maintaining the principle of academic freedom; (3) to ensure incentives and safeguards for economical use of Government money. The first of these is, of course, violated absolutely by the Government's decision, but it is with the third that the report, apart from its scrutiny of the University Grants Committee, is essentially concerned.

There are now four parties to the present system: the Treasury, the Department of Education and Science, the University Grants Committee and the universities themselves. While the Estimates Committee is sometimes critical of the Department of Education and Science, and the universities, in general, are afraid that their claims may not be put with the same energy, *vis-à-vis* the rest of the education, as when the University Grants Committee approached the Treasury direct, this was vigorously denied by the Department, which, like the Treasury, puts the main responsibility for financial control on the University Grants Committee. It continues to be the view that a proper regard to the academic independence of the universities should be the counterpart of a responsible attitude in the universities towards Government money. The Estimates Committee agrees with the Robbins Committee in maintaining the principle of a Committee independent of politics and not subject to ministerial directions—yet maintaining close contact with the organization of Government—which advises on the magnitude of the amounts needed and which distributes the funds available.

The report shows that it is open to question whether the University Grants Committee, as at present constituted, can adequately fulfil these functions. It points to the heavy responsibilities of the Chairman and his growing number of largely routine duties. The routine work of members of the Committee is also so onerous that it could prevent them from giving to the universities as a whole, and to the newer universities in particular, the sort of guidance they need to frame their building programmes in line with national needs and financial possibilities. The Estimates Committee received considerable evidence that the University Grants Committee is understaffed: while paying tribute to the devotion and public spirit of past and present members of the Committee, it considers that growing responsibilities of the Committee call for much more full-time responsibility than at present. It recommends, therefore, that the Secretary of State for Education and Science should review the composition and responsibility of the University Grants Committee to discover whether it is advisable to increase the number of members and to require more of them to undertake full-time duties.

There are other specific recommendations. The Deputy Chairmanship should be made a full-time appointment, and it is recommended that the time-table of visitations should be rearranged so that they are spread over the whole quinquennium in order to facilitate two visits to each university. The Committee's Finance Division should be strengthened by full-time services of the statistician, with, if necessary, further statistical help for

the other Divisions, and a full-time cost accountant attached to the Committee as a whole. It is also recommended that an immediate review should be made of the Architect's Division so that a better career structure can be set up, and, to secure an immediate increase, that full attention should be paid to the secondment of additional staff from other Government departments. In reviewing the Architect's Division, the authorization of additional posts (one to be filled by a consulting engineer) should be considered.

By strengthening in this way the technical expertise available to the Committee, particularly in accountancy techniques, the Estimates Committee hopes that the University Grants Committee will be able to develop cost control more effectively and also to give more constructive and effective guidance to the universities in planning university buildings. As to informing universities of national needs, the Estimates Committee considers that this is primarily a responsibility of the Department of Education and Science. It recommends that the Department should enlarge the functions of its officers responsible for collecting and processing information on national needs for graduates in industry and elsewhere. Jointly with the University Grants Committee and the Treasury, the Department should undertake urgently a review of the quinquennial system in the light of the requirements suggested by the Treasury, and any changes seen to be necessary should be put into effect in the early part of the next quinquennium.

Two of the Treasury suggestions are worth noting. The system should provide ample time for the University Grants Committee to assess the requirements and efficiency of new universities and, moreover, it should provide the universities with a reasonable assurance that the necessary funds will be available so that they can proceed in accordance with approved targets. It should also provide the Government with as good a forecast as possible of the Government recurrent finance which would be needed over a period—realistically not more than five years—and it should be capable of review and being brought up to date at intervals. The system should not involve too detailed a control of expenditure by the universities, and also provide Parliament with an assurance that the sums provided are adequate to finance universities in accordance with Government policy and yet provide proper incentives to efficiency in university administration.

Five other recommendations are addressed to the University Grants Committee itself. The procedure for bringing up and dealing with claims by universities for a supplement to the recurrent grant is subject to exercises of judgment to an extent which the Estimates Committee regards as unfair to the universities. Accordingly, it recommends that the University Grants Committee should inform the Committee of Vice-Chancellors that if the claims of universities are co-ordinated and submitted by them at any time, such claims will be transmitted as soon as possible for the Government's decision. On the control of building programmes it recommends that the University Grants Committee should invariably receive confirmation of the Government allocation of building starts not less than four years in advance and, as soon as possible after this has been done, the Committee should make its allocation to individual universities. It also recommends that the University Grants Committee should inaugurate an exercise to work out standard requirements for university buildings and that the more general requirements should be given effect as soon as possible.

This suggestion originated with the Royal Institute of British Architects, whose evidence was that the University Grants Committee was relating costs not to standards but the money available and the bulk of building. The Estimates Committee appreciates the difficulty of calculating maintenance costs and recognizes that the Department of Education and Science could help by making available all its information on maintenance costs. None the less, the Committee recommends that the University Grants Committee should also examine the proposal that contractors tendering for university buildings should be asked to tender for their maintenance as well, although the proposal at first sight appears to cut across demarcation lines between capital and recurrent expenditure.

Finally, the Estimates Committee hopes that if increased staff can be attracted to the Architects' Branch of the University Grants Committee they will undertake research into university building work on a larger scale. Only a few universities have yet made use of industrial building techniques, and the evidence submitted to the Committee suggested that the lack of research at national level to discover what systems are suited to different universities was the main factor. Other points to which the Committee directs attention are the tendency for savings to be in time and future maintenance rather than immediate costs and the impracticability of using any system to full advantage without a capital programme of several years. The fifth recommendation to the University Grants Committee is thus that the Committee should invite the National Building Agency and experienced contractors to pool all available information on industrial building techniques, and to combine with them to discover which systems are suitable for the different regions, categories and conditions of individual universities.

While, as already noted, the Estimates Committee's scrutiny did not extend to the scale of university expansion or to the purpose of a university education, it nevertheless gave the whole system a thorough examination, from which the University Grants Committee and the system as a whole emerge with much more credit than some critics have been disposed to allow. Its recommendations, if adopted, should strengthen the Committee and the system, where weaknesses have for some time been widely recognized, but there seems little reason to anticipate drastic modification of the Committee or the quinquennial system as a result of the further enquiries recommended. That is subject to the observance of the fundamental conditions on which the whole system rests. It is here that the Government's own action causes the gravest anxiety and the most serious doubts. University finance and university expansion are far too complex and technical for political prejudices to operate if waste of national resources is to be avoided and if the nation is to receive a due return from the large expenditure now involved. The scale of expansion and its rate must obviously be determined by political considerations, but those considerations must be limited to the extent of national resources available and to national needs in the light of other conflicting claims. They cannot be determined by considerations of party advantage.

Once the scale and rate of expansion are agreed the resources committed should be beyond interference. A policy of start-and-stop or even of go-slow destroys the whole basis of efficiency. It should be clear that the latest Government decision not only ignores the responsible advice of the Plowden Committee, but also the supporting

evidence adduced in the Estimates Committee's enquiry. It makes nonsense of at least three of the recommendations advanced for strengthening the present system and removing certain weaknesses which have been detrimental to full efficiency and led to certain waste of resources. Reasons advanced in the House of Commons debate on August 3 by Mr. R. E. Prentice are quite untenable in the light of this report, and to make exceptions in development areas makes nonsense of university policy. If the Government and the nation wish to expand the universities at a certain scale and rate they must will the means, even if it involves curtailing available resources elsewhere. If they are not prepared to will the means, the universities themselves must decide on the scale and rate of expansion which they can achieve without undermining either the standards of their work or the purpose of their education.

## THE CARNEGIE UNITED KINGDOM TRUST

### Welfare In Trust

A History of The Carnegie United Kingdom Trust 1913-1968. By W. Robertson. Pp. 282. (Dunfermline: The Carnegie United Kingdom Trust, 1964.) n.p.

THIS book was commissioned by the Carnegie United Kingdom Trust to commemorate its jubilee. It is not for sale but can be borrowed from any public library.

It is a faithful record of the way in which the Trust, founded by Andrew Carnegie in 1913, has been interpreted and administered by the original Trustees and their successors. Though the author has succeeded on the whole in presenting his subject against the background of changing social conditions, which was essential if the Trust is to be seen in perspective, his story is not always easy to follow. This is because it has not been consistently handled either chronologically or by subject. The variety of subject-matter and the length of the story may have made this unavoidable; but it is a drawback for the reader.

The Trust, with an original capital of ten million dollars, was less rich than some of the great American Trusts and indeed than some of those more recently formed in Great Britain, but it was the first of its kind in the United Kingdom and it has been able both to exert considerable influence on social policy and to make possible and encourage a very large number of individual schemes of varying size and importance.

Its activities have from the first been largely determined by two factors—the terms of the trust and the methods of grant allocation.

The terms of the Deed, "the improvement of the well-being of the masses of the people of Great Britain and Ireland", were sufficiently wide to allow the trustees to support a number of different kinds of project at any one time and also to change their overall policy to meet changing social needs and conditions.

The method of grant allocation adopted at the outset, and unchanged in essence since, has been to leave the initiation not only in decision making but even in planning almost exclusively in the hands of individual trustees rather than in those of a professional secretariat. The Trustees over the years have been well served by their secretaries so far as the collection of data and detailed management are concerned, but they do not appear, by and large, to have looked to them for a dynamic lead. Policy has not been thought out from first principles but has tended to grow step by step in a somewhat haphazard way dependent on the particular interests and strength of character of individual trustees and their friends. Projects that have been put up to the Trust have been examined, and their acceptance determined, in relation to the kind

of things that the Trustees happened to be supporting at the time, provided in a general way that they did not conflict too obviously with certain criteria that have remained constant: first that money should not be provided for what was a statutory obligation (and even here exceptions were made when a trust contribution was held, often rightly, to provide a necessary spur to statutory action), and secondly that money should only be given to projects which included some element of pioneering and experiment—and here too exceptions were made.

Thus much has depended on the interests and personalities of individual trustees, and these have undoubtedly been a remarkable and devoted band of men and women with a wide knowledge of educational and social problems. The projects which they have brought forward for consideration and which have won support have been varied in nature, in size and in importance, and any estimate of their relative value is bound to be largely subjective, since it is a matter of opinion whether it is better to spend money on, for example, libraries or youth hostels, child welfare or the handicapped. It is, however, possible to make some judgments regarding the success of the different projects, and this the author has attempted to do. While paying tribute to the large number of movements where the support of the Trust played an important part, such as libraries, rural development, help for the handicapped, he has not hesitated to mention less-successful ventures such as the Bureau of Current Affairs and the Land Settlement Scheme.

Success may be judged in relation both to the satisfactory outcome of the particular project and to the effect that project has on the development of social policy. A community centre or a youth hostel may be a success in itself for the opportunities it offers its members; but it will be a greater success if it shows the way for other centres and hostels which will serve a wider public. This the Trust has always recognized; but at the same time it has never lost sight of the value of supporting even quite small groups in their efforts on behalf of the community. Its support of pioneering work and of voluntary effort has been among its main contributions to social progress.

Whether or not the projects supported by the Trust have been successful in the double sense mentioned above has depended to a great extent on its co-operation with voluntary bodies which are in close touch with contemporary social needs and problems. Perhaps the most outstanding example of such co-operation has been that with the National Council of Social Service, particularly in the sphere of rural work. Started in the early days of Prof. W. G. S. Adams, this has continued to be a growing partnership of great value to both sides and to the causes which they sponsored. Village halls, of which more than two thousand have been assisted by the Trust, are the visible sign of work in the countryside which covers a wide variety of interests and has enriched the lives of countless country men and women. The Trust provided the money and the National Council the expertise—not only knowledge of how village life could best be enriched, but also detailed information connected with applications for grant.

*Welfare in Trust* is a worthy title for this record of fifty years' service to the community. Five million pounds have been distributed to good causes during this period and the Trustees have faithfully carried out the wishes of the founder. They have contributed to "the well-being of the masses" by supporting libraries, village halls, adult education, research, music and the arts, playing fields and youth work and by welfare schemes for family and community. They have made it possible for national organizations concerned with these things greatly to expand their work and have at the same time encouraged small groups and even individuals to pioneer and to experiment. Andrew Carnegie could well be proud of the extent and value of the work made possible by his foundation.

MARY MORRIS

## SPACE RESEARCH

### Space Research V

Proceedings of the Fifth International Space Science Symposium, Florence, May 12–16, 1964. Edited by D. G. King-Hele, P. Muller and G. Righini. Pp. xix+1248. (Amsterdam: North-Holland Publishing Company, 1965.) 300s.

THE annual symposium organized by the Committee for Space Research is an event of primary importance for all participants in space research. *Space Research V* is concerned with the proceedings of the fifth such international symposium. It contains papers dealing with the physical side of the subject only. Papers dealing with life sciences in relation to space research are to be published in another volume. Even with this limitation on its contents it is a tremendous tome. It is made up of 1,248 pages and contains 154 papers grouped under twelve headings. It weighs nearly 6 lb. and costs £15. It is virtually impossible to give anything approaching an adequate summary of its contents as the contributions range over many fields. Many of them are not directly related, other than through the fact that they refer to results obtained by the use of satellites, rockets or balloons. The twelve sections give some idea of the range of matter. They are: (1) "Interaction of Energetic Particles with the Atmosphere"; (2) "Ionospheric Processes and Anomalies"; (3) "Precipitation and Effects of High Energy Particles"; (4) "Radiation Belts"; (5) "Solar Radiation and Interplanetary Medium"; (6) "Ionosphere"; (7) "Atmospheric Structure and Composition"; (8) "Galactic X-ray Astronomy"; (9) "Tracking of Satellites"; (10) "Dynamics of Satellites"; (11) "IQSY Programmes and Results"; (12) "Upper Atmosphere Studies with Rockets and Satellites".

Most of the papers are in English, a few in French. The majority have been abstracted in Russian. We are informed in the editorial preface that there were more than 450 participants representing thirty-three countries. Of the contents it is difficult to say more than that they form an invaluable compilation of results both experimental and theoretical and give an excellent cross-section of work in progress at the time of the symposium. Most of the topics included are now well-established fields of activity, but a recent and very welcome newcomer to the scene is that labelled "Galactic X-ray Astronomy"—a tantalizingly short section of less than five pages made up of three papers in the form of abstracts. This is a subject likely to develop much in the years ahead and indeed has already made appreciable progress since the symposium was held.

One is filled with admiration for the way the editors have faced up very successfully to an obviously difficult task. The dividing line between some of the sections is rather shadowy and there is naturally in such cases some overlap of content, but on the whole they are fairly clearly defined and self-contained. While the contributions vary in importance, none is unimportant, and all groups of workers in the field of space research will surely find it necessary to possess, or have access to, a copy of the *Proceedings*. The very high price, however, is likely to deter many individual workers from buying it for themselves, and this raises the sole serious criticism of the book—one wonders whether it was necessary to reproduce the *Proceedings* on the scale in which they have been reproduced, or alternatively whether it was necessary for all the sections concerned with the physical sciences to be collected together in one volume. There must be many space research workers who would gladly have on their shelves copies of the sections concerned with their field of interest but who nevertheless cannot afford to pay the very high price demanded for the complete set of sections, and it occurs to me that if it could have been split up into two or three volumes each containing three or four cognate sections it would have met the needs of individuals

better. As it is, it seems that only research institutions and universities can afford to purchase it. While many of the papers are full-scale papers of twenty pages or more, others are much shorter, and some are very short and take the form of abstracts. In so much as it is typical of papers presented at conferences generally that they are published afterwards in modified form in other journals, one wonders whether as an alternative a good proportion of the papers reproduced in this set of *Proceedings* could not also have been reduced in size or even published as abstracts, so reducing both size and cost of the volume. All this sounds like carping criticism of a very important and excellent book, but it would seem that one consequence of this wholesale publication has been that very nearly a year elapsed between the holding of the symposium and the publication of its *Proceedings*. In fact, publication occurred only a short while before the sixth symposium was held in May 1965 so that shortly after publication a number of the papers were already superseded by papers presented at the sixth symposium.

The production of the book is up to the usual high standard of the North-Holland Publishing Company, and misprints, so far as I have been able to observe, are few in number and trivial in nature. E. A. STEWARDSON

## THE CONTEXT OF LIFE

### Handbook of Physiology

A Critical, Comprehensive Presentation of Physiological Knowledge and Concepts. Edited by D. B. Dill, E. F. Adolph and C. G. Wilber. Section 4: Adaptation to the Environment. Pp. ix+1056. (Washington, D.C.: American Physiological Society; London: Baillière, Tindall and Cox, Ltd., 1964.) 288s.

SEVERAL volumes of the *Handbook of Physiology* are now on the library shelves, if not permanently and irritatingly out on loan. Those earlier doubts as to whether it is still possible to produce a literature both so contemporary and so permanent as to deserve the rank of 'handbook' have largely faded into the background. Since few besides a reviewer will have the time or the occasion to study a volume of the *Handbook* in its entirety, and private possession will be exceptional, these volumes must be enjoyed in small doses and referred to time and again by many individuals. It is quite likely, then, that their physical lives will expire before the subject-matter has lost its relevance, accuracy and appeal. Surely few librarians would complain of that fate for these expensive, but not unreasonably expensive, volumes.

This volume on adaptation to the environment is essentially an American production. Although valuable contributions are made by authors from ten other countries with representatives from every continent, 46 of the 64 contributions emanate from laboratories in North America. The broad biological approach to the subject, and the depth of the appreciation of the biological significance of adaptation owe much to those exciting schools of physiological zoology which are particularly active and successful in the United States.

After three excellent opening chapters on perspectives concerning the history, theory and general properties of adaptation, which serve to determine the dimensions of the subject, subsequent contributors settle in to the immense task of filling in the details so far as they are known. Following a chapter on the cellular level of adaptation, the adaptive capacities of the nervous, muscular, special sensory, cutaneous, skeletal, cardiovascular, respiratory, digestive, excretory, osmoregulatory and thermoregulatory systems are considered in turn. There are chapters which consider the geophysical environment itself, and laboratory facilities for the provision of controlled experimental changes in the environment. The effects of cold, dry heat and humid heat on

arthropods, reptiles, birds, mammals and man are then discussed together with chapters on the hibernators and aestivators. The next group of papers considers the adaptations of animals in aquatic environments, and is followed by four chapters on animals in toxic environments which include the effects of insecticides on insects and why some individuals survive to breed resistant strains. The effects of polluted air, industrial chemicals and narcotic analgesics on man and other animals are also discussed. The effects of and responses to altitudes range from those of man permanently resident high on the Andes to those of man temporarily resident in a space capsule. Finally, there is a group of papers dealing with the adaptation of man to a miscellany of circumstances, both natural and not so natural, in which he may find himself, or in which he is wont to place himself. These include his responses to caloric deficiency, repeated injury, solar and ionizing radiations, motion and noise.

Life and the environment in which it thrives must be considered together once the physiologist concerns himself with the functions of whole and integrated organisms, or seeks to make comparisons between individuals or species. Gehlne (p. 259) says "In whatever region of the Earth they have settled, animals have adjusted their lives to the environment", and Thomas (p. 210) points out that "all truly physiological reactions of an organism to changes in its environment are basically adaptive in character". The realization that an organism is, in a sense, the product of its own environmental history has grown clearer over more than 2,000 years since Hippocrates recognized the role of adaptive factors in relation to health and disease. The properties common to most organisms such as the use of high-energy phosphate bonds for energy transfer, genetic coding by nucleotides, specificity of proteins as catalysts, and the selective permeability of cell surfaces, must have become established at the very dawn of life before the creation of a stable reproducing cell. All subsequent evolution in organizational complexity and in diversity of both form and function must exist because of the survival of chance mutations which afforded some advantage to the organism in relation to its environment. Adaptation to the environment, then, is no peripheral aspect of physiology of interest only to those who are concerned with the reactions of man and other animals when exposed to both natural and unnatural variations in ambient conditions. On the contrary, adaptation to the environment is the very *raison d'être* of the integrative complexities of all organisms.

This volume is concerned with two distinct levels at which adaptation can be considered. One relates to the genetically fixed characteristics which permit one species to occupy a particular ecological niche, or which increase the chances of survival of an individual in the face of existing hazards, or of a change in the environment which is otherwise disastrous to the species. These characteristics are at all levels of biological organization from the sub-cellular to that of gross morphology. The other is that complex of limited physiological and behavioural adjustments which all organisms can make in the face of limited changes in the environmental conditions, and referred to as 'acclimatizations'. Here, again, many tissues and systems may be involved, and the extent to which individuals can acclimatize may also be genetically determined.

Adaptation to the environment as the determining factor in evolution has depended essentially on mutations which affect the chances of survival of the individual up to the time of its own reproductive activity, since survival beyond this phase in life is of little or no evolutionary consequence. However, modern man now demands 100 per cent survival into adult life and seeks to give every individual the chance to procreate irrespective of genetic make-up. When man becomes the dominating interest in this volume, genetic differences between individuals become of less importance than the general ability of

most individuals to adjust themselves to changing environmental circumstances. By learning to control both the environment in which he lives, and the influence of the environment on himself, man has created an unparalleled change in the course of Nature.

"This was the law of the Yukon,  
that only the strong shall thrive,  
That surely the weak shall perish  
and only the fit survive".

While this shift in the principles and practice of adaptation to the environment becomes abundantly clear as one peruses this volume, there is, wisely perhaps, no direct comment on it, still less any speculation on its possible consequences.

The *Handbook of Physiology* is described as a "critical, comprehensive presentation of physiological knowledge and concepts". It is unlikely that any other volume of the *Handbook* will attempt to do just this for so vast and relatively unexplored a field, but this aspiration is largely achieved. One can only express admiration for a remarkable compilation. The contributors, in general, are quick to point out the inadequacy of their knowledge, and the young research worker who has not yet been persuaded to direct his whole attention to a more confined aspect of biological function will find the inspiration here for studies which could fill many lifetimes.

Each contributor has been given ample space to state his thesis, and the volume avoids that brittle economy of words which sometimes mars the pleasure of reading scientific literature. There are repetitions, here and there, of matters already discussed by earlier contributors, but no one should cavil at this since sections are referred to in isolation from each other. Each chapter should be, and is, self-contained.

Whatever the policy may be for other volumes in this series, this particular volume should be within the reach of every teacher and research worker in the field of biology.

J. BLIGH

## HUMAN GENETICS AND CYTOLOGY

### Les Chromosomes Humains

(Caryotype Normal et Variations Pathologiques.) Par Prof. Raymond Turpin et Prof. Jérôme Lejeune. Pp. viii+535. (Paris: Gauthier-Villars, 1965.) 54 francs.

### Human Genetics

Cold Spring Harbor Symposia on Quantitative Biology, Vol. XXIX. Pp. xiv+492. (Cold Spring Harbor, L.I., New York: The Laboratory, 1965.) 15.00 dollars.

A JOINT review of these two recent volumes can be justified by considering them as complementary. Both publications are mainly summaries of the work of many research workers during the past five years, but the book by Turpin and Lejeune, having only one additional contributor and a single subject-matter, the chromosomes, is more homogeneous and rounded in presentation than the symposium volume which contains 44 separate contributions by different authors.

*Les Chromosomes Humains* starts with a history of our knowledge of the human chromosomes, touches on the techniques for their investigation and then describes the normal human karyotypes. Three chapters deal with the numerical anomalies of autosomes and one chapter with the anomalies of their structure, followed by a chapter on chromosomal studies in leukaemias and cancer. Three further chapters are devoted to the numerical and structural aberrations of the sex chromosomes, and one is concerned with hermaphroditism and pseudo-hermaphroditism. Chromosome differences between twins and the mechanisms and effects of abnormal sex chromosomes are also separately treated. Finally some biochemical pecu-

liarities which are associated with chromosomal abnormalities are discussed by H. Jerome. The approach to most problems presented in this book is both cytological and clinical. The origins of mosaicism and the various hypothetical mechanisms which may result in abnormal karyotypes are discussed at some length, and it is probably from these parts of the book that some controversy may arise. There are numerous graphs, illustrations and tables. The bibliography covers publications well into 1964 and is invaluable as a source of information. The rapidity of discovery and development in this field is, however, such that already, a few months after the publication of the book, new important information is available which could not be included.

*Human Genetics* deals with three active fields of research, namely population studies, the genetics of somatic cells and cells in culture, and human proteins. In it, chromosome anomalies play only a minor part in the second section, which deals with cell culture. There the main emphasis is on the sex-linked genes, and the state of the X chromosome is discussed in conjunction with the Lyon hypothesis. Otherwise, this part is mostly concerned with cell selection, cell antigens and the localization of biochemical mutants. Interesting structural effects of irradiating chromosomes in cultures and of radiomimetic substances are reported, but the analysis of gene mutations by such means is still in its infancy. Other techniques may prove more successful in this field. The impression gained from reading this section of the symposium is one of rapid growth in separate specialized groups without, as yet, much regard to the possibilities of integration or generalization. On the other hand, the last section of the monograph, which deals with the genetics of human proteins, covers the considerably more homogeneous and well-established subject of the polymorphisms of haemoglobins, haptoglobins, gammaglobulins and certain enzymes as well as immunogenetics. There the mutual understanding of the several participants is also obvious from the quality of their discussions.

The first part of the book contains studies of many different kinds of human population; this subject seems to be in a state of flux so that a few contributions appear a little repetitive and perhaps tired, while others hint at novel approaches. General problems such as the effects of drift, of the genetical load, of lethal equivalents, polymorphism, and the effects of pleiotropism are once more discussed. Perhaps more rewarding are specific genetical studies on populations in Brazil, India, the American Indians as well as the 'Amish'. Most promising is the study of the nature and consequences of ethnic mixtures among the immigrant communities of Israel; the information summarized in this paper will provide an important and unique base line for future research. A lively contribution by Gajdusek describes some very unexpected consequences of the highly lethal Kuru disease in New Guinea which has led to a considerable numerical increase in the affected Fore population. His vivid account of other vagaries of 'selection' and the general unpredictability of events which control the genetical fate of small primitive people provides a most impressive and healthy contrast to the traditional unquestioning assumptions of gene equilibria, or at best the slow action of persistent selective forces in all circumstances. These have operated in the large populations of modern man, and some of their effects are described by the other contributors.

In the framework of a short review it is unfortunately impossible to do justice to all the contributions in the symposium, nor is it possible to offer detailed criticism. While most papers individually come up to the high standards of the Cold Spring Harbor Symposia, it appears to me that as a synthesis this particular volume does not reach the excellence of its best predecessors. This is borne out by the last concluding chapter, where Bentley Glass more or less despairs of summarizing the heterogeneous subject-matter.

H. KALMUS

**Egypt to the End of the Old Kingdom**

By Cyril Aldred. (The Library of Early Civilizations.) Pp. 143 (illustrations). (London: Thames and Hudson, 1965.) 30s.

**Early Mesopotamia and Iran**

By M. E. L. Mallowan. (The Library of Early Civilizations.) Pp. 142 (illustrations). (London: Thames and Hudson, 1965.) 30s.

**B**OTH these authors are front rank authorities on their subjects, and both are able to write clearly and simply. In neither case is it the intention to offer a book for the specialist; what is intended is to provide a short, clear, up-to-date account of the story of both these regions, so vital to the development of human civilization. Both volumes are profusely illustrated, not a few examples being in colour.

The Egypt volume starts with a detailed chronology and a map. Chapter one deals with the beginnings of human settlement, and rightly mentions finds of early palaeolithic date. An actual date of 200,000 years ago can only be guess-work; they may well be older! The change-over from hunting to farming is next dealt with. This was one of the great stages in human development. For the first time community life was possible and village life evolved. There follows a brief account of the early pre-dynastic period, mention being made of such early cultures as those from the Fayum, Merimde and Badari. Illustrations of the typical tools and pottery are given. In the same way the later predynastic period is dealt with in the next chapter, and following this there is an account of the transition to the Dynastic Age. The Dynasties I-VI next pass under review, and there is a concluding chapter on the sculpture of the Old Kingdom. For anyone wishing to know the essentials of early Egyptian archaeology, and what has been unearthed, this book can be strongly recommended.

Much of what has been said about Cyril Aldred's book on Egypt can be said about M. E. L. Mallowan's *Early Mesopotamia and Iran*. Once again the volume is profusely illustrated, not infrequently in colour. There are chronological charts and a map. The first chapter deals with the urban development in Uruk and Iran somewhere round about 3500 B.C. Many examples of the painted pottery from this early period are indeed lovely. We pass on to an account of the temples in the plains and their associated finds and sculptures. At this time we can note the invention of writing, which has had so profound an influence on civilisation. There is an interesting account of the daily life at Uruk. Next we pass to the early Sumerians and their culture, followed by the early dynastic period when we note a considerable improvement in architecture and ornaments of all kinds. For example, the well-known Royal Standard of Ur, which illustrates the activities of the King and his court both in peace and in war, is an object of great beauty. Some of the sculptures, too, show an amazing control over the medium when the early date is remembered. Once again this is a volume to be read by anyone wishing to know something of the fundamentals of the early civilizations in Mesopotamia, an area which has played such an important part in the growth of civilization as we know it to-day.

M. C. BURKITT

**Tensors in Mechanics and Elasticity**

By Prof. Leon Brillouin. Translated from the French by Robert O. Brennan, S.J. (Engineering Physics: an International Series of Monographs, Vol. 2.) Pp. xviii + 478. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd. 1964.) 89s. 6d.

**TENSORS in Mechanics and Elasticity** is a translation from the French of the 1938 edition of Prof. L. Brillouin's well-known text-book. It is, of course, a classical book in this field and nowadays forms an excellent introductory text. Although, to-day, there are many

text-books (in English) which describe the use of tensors in physics in great detail, there is still room for the broad introductory treatment. The clarity of Prof. Brillouin's writing has been carried through the translation. On the whole the text is given in good clear English, although there are places where it is slightly stylized.

Unfortunately it is inevitable that this book is dated both in the subject material and in the reference list, neither of which has been brought up to date during the translation. However, because of the basic work covered, this is not too great a disadvantage. The material covered runs from a description of vector geometry, affine geometry and Riemann space to wave mechanics and elastic waves in solids. The idea of a tensor is introduced before proceeding to a discussion of the role of tensors in physics. The reader is led through the mathematical analysis step by step. This part of the book occupies the first seven chapters. A discussion of problems in mechanics and elasticity then fills the remaining five chapters. This discussion demonstrates how tensors form a natural basis for, and so simplify, the treatment of these subjects. Altogether it is a useful addition to the English booklist.

The production is good and the print is clear and easy to read; unfortunately this seems to have kept the price high.

P. A. EGGLESTAFF

**Radioactive Isotopes in Instrumentation and Control** By N. N. Shumilovskii and L. V. Mel'tser. Translated by R. F. Kelleher. Translation edited by P. J. Blaetius and G. A. Young. (International Series of Monographs on Nuclear Energy. Division 4: Isotopes and Radiation, Vol. 3.) Pp. xiv + 198. (London and New York: Pergamon Press, 1964.) 70s. net.

**U**NTIL recently the application of radioactive isotopes to control engineering was mainly confined to a few simple techniques such as the use of tracers, and the measurement of thickness or level. At present there is an increasing interest in more sophisticated techniques which permit the measurement of fluid flow, pressure, humidity, and chemical composition. Descriptions of single techniques, or brief reviews of specialized applications, are scattered in the literature, making the subject difficult to include in formal studies. The present monograph, by authors who have an international reputation in the field, not only rectifies this but will also probably do much to stimulate the imagination of instrument designers and manufacturers.

The introduction, which occupies a quarter of the book, is unsatisfactory since it assumes no previous knowledge and yet attempts too briefly to cover nuclear physics and statistics up to the point of practical application. However, for a reader with previous knowledge of conventional nuclear instrumentation the introduction may prove useful for its formulae, arranged in convenient form for numerical interpretation.

Other chapters are concerned with measurements of thickness and density by absorption and backscattering methods, the measurement of level and flow of liquids, and the measurement of flow and pressure of gases. There is also a chapter on composition control by a variety of interesting techniques, including ionization methods, absorption and scattering, radiation spectrometry, and neutron activation. Two chapters are devoted to system analysis. One of them gives a most useful analysis enabling the radioactivity of the source to be minimized for a particular dynamic response. The other gives an analysis of electromagnetic relay operation.

The misprints are few, and most of them are obvious. However, a few could be misleading to a reader without previous nuclear knowledge (for example, "neutron" for "neutrino" on p. 3). The uncustomary symbols in the equations were found stimulating rather than annoying, and the book can be recommended for the inspiration it will give to instrument designers in industry.

B. M. WHITLEY

## A BIOLOGICAL RETROSPECT\*

By SIR PETER MEDAWAR, F.R.S.

Director, National Institute for Medical Research

THE title of my presidential address, you will have discerned, is "A Biological Retrospect", and on the whole it has not been well received. 'Why a biological retrospect?', I have been asked; would it not be more in keeping with the spirit of the occasion if I were to speak of the future of biology rather than of its past? It would indeed be, if only it were possible, but unfortunately it is not. What we want to know about the science of the future is the content and character of new scientific theories and ideas. Unfortunately, it is impossible to predict new ideas—the ideas people are going to have in ten years' or in ten minutes' time—and we are caught in a logical paradox the moment we try to do so. For to predict an idea is to have an idea, and if we have an idea it can no longer be the subject of a prediction. Try completing the sentence 'I predict that at the next meeting of the British Association someone will propound the following new theory of the relationships of elementary particles, namely . . .'. If I complete the sentence, the theory will not be new next year; if I fail, then I am not making a prediction.

Most people feel more confident in denying that certain things will come to pass than in declaring that they can or will do so. Many a golden opportunity to remain silent has been squandered by anti-prophets who do not realize that the grounds for declaring something impossible or inconceivable may be undermined by new ideas which cannot be foreseen. Here is an instructive passage from the philosophic writings of a great British physiologist, J. S. Haldane (father of J. B. S.). It comes from *The Philosophy of a Biologist* of 1931, and its subject is the nature of memory in a very general sense that includes 'genetic memory', for example, the faculty or endowment which ensures that a frog's egg develops into a frog and, indeed, into a particular kind of frog.

Haldane is very critical of the theories of memory propounded by Ewald Hering and Richard Semon, who "assume that memory in general is dependent on protoplasmic 'engrams', and that germ-cells are furnished with a system of engrams, functioning as guide-posts to all the normal stages of development". ('Engrams', I should explain, are more or less permanent physical memory traces or memory imprints that act as directive agencies in development<sup>1</sup>). "This theory", Haldane goes on to say, "has quite evidently all the defects of other attempts at mechanistic explanations of development. How such an amazingly complicated system of signposts could function by any physico-chemical process or reproduce itself indefinitely often is inconceivable<sup>2</sup>."

What Haldane found himself unable even to conceive is to-day a commonplace. Only twelve years after the publication of the passage I quote, Avery and his colleagues had determined the class of chemical compound to which genetic engrams belong. In the meantime our entire conception of 'the gene' has undergone a revolution. Genes are not, as at one time or another people have thought them, samples or models; they are not enzymes or hormones or prosthetic groups or catalysts or, in the ordinary sense, agents of any kind. Genes are messages. I think Kalmus<sup>3</sup> was the first to use this form of words, but the idea that a chromosome is a molecular code

script containing a specification of development is Schrödinger's<sup>4</sup>.

My purpose in this address is to identify some of the great conceptual advances that have taken place during the past twenty-five or thirty years on four different planes of biological analysis. As I have pointed out elsewhere<sup>5</sup>, working biologists tend nowadays to classify themselves less by 'subjects' than by the analytical levels at which they work—a horizontal classification where the older was vertical. So we have molecular biologists, whose ambition is to interpret biological performances explicitly in terms of molecular structure; we have cellular biologists, biologists who work at the level of whole organisms (the domain of classical physiology), and biologists who study communities or societies of organisms. We can discern each of these four strata within each 'subject' of the traditional, that is, the vertical, classification. There are molecular and cellular geneticists, geneticists in Mendel's sense, and population geneticists. So also in endocrinology or immunology: each is now studied at the molecular and cellular level as well as at the level of whole organisms. They abut into the population level, too: we study the effects of crowding and fighting on the adrenals and so indirectly on reproductive performance, and we study the epidemiological consequences of natural or artificial immunization and the evolutionary consequences of epidemics. I have noticed that a biologist's interests and understanding, and also, in a curious way, his loyalties, tend to spread horizontally, along strata, rather than up and down. Our instinct is to try to master what belongs to our chosen plane of analysis and to leave to others the research that belongs above that level or below. An ecologist in the modern style, a man working to understand the agencies that govern the structure of natural populations in space and time, needs much more than a knowledge of natural history and a map. He must have a good understanding of population genetics and population dynamics generally, and certainly of animal behaviour; more than that, he must grasp climatic physiology and have a feeling for whatever may concern him among the other conventional disciplines in biology (I have already mentioned immunology and endocrinology). There is no compelling reason why he should be able to talk with relaxed fluency about messenger-RNA, and it is not essential that he should ever have heard of it—though an unreasonable feeling that he 'ought' to know something about it is more likely to be found in a good ecologist than in an indifferent one.

I shall now take one example from each of these four planes of biological analysis and try to show how our ideas have changed since the last Cambridge meeting of the British Association in 1938—a period that corresponds roughly with my own professional lifetime.

## Population Genetics and Evolution Theory

Biologists of my generation were still brought up in what I call the 'dynastic' concept of evolution. The course of evolution was unfolded to us in the form of pedigrees or family trees, and we used the old language of universals in speaking of the evolution of *the* dogfish, *the* horse, *the* elephant and, needless to say, of Man.

The dynastic conception coloured our thoughts long after the revival of Darwinism had made it altogether

\* Presidential address delivered to Section D (Zoology) on September 2, 1965, at the Cambridge Meeting of the British Association for the Advancement of Science.

inappropriate. By the 'revival of Darwinism' I mean the reformulation of Darwinism in the language of Mendelian genetics—the work, as we all so very well know, of Fisher, J. B. S. Haldane, Wright, Norton and, in a rather qualified sense, of Lotka and Volterra. The subject of evolutionary change, we now learned, was a population, not a lineage or pedigree: evolution was a systematic secular change in the genetical structure of a population, and natural selection was overwhelmingly its most important agent. But to those brought up in the dynastic style of thinking about evolution it seemed only natural to suppose that the outcome of an evolutionary episode was the devising of a new genotype—of that new genetical formula which conferred the greatest degree of adaptedness in the prevailing circumstances. This improved genetic formula, a new solution of the problem of remaining alive in a hostile environment, would be shared by the great majority of the members of the population, and would be stable except in so far as it might be modified by further evolution. The members of the population were predominantly uniform and homozygous in genetic make-up, and, to whatever degree they were so, would necessarily breed true. Genetic diversity was maintained by an undercurrent of mutation, but most mutants upset the hard-won formula for adaptedness and natural selection forced them into recessive expression, where they could do little harm. When evolution was not in progress natural selection made on the whole for uniformity. Polymorphism, the occurrence of a stable pattern of genetic inequality, was recognized as an interesting but somewhat unusual phenomenon, each example of which required a special explanation, that is, an explanation peculiar to itself.

These ideas have now been superseded, mainly through the empirical discovery that natural populations are highly diverse. Chemical polymorphism (allotypy\*) is found wherever it is looked for intently enough by methods competent to reveal it. The molecular variants known in human blood alone provide combinations that far outnumber the human race—variants of haemoglobin, non-haemoglobin proteins, and red-cell enzymes; of red-cell antigens and white-cell antigens; and of haptoglobins, transferrins and gamma globulins. To-day it is no longer possible to think of the evolutionary process as the formulation of a new genotype or the inauguration of a new type of organism enjoying the possession of that formula. The 'product' of evolution is itself a population—a population with a certain newly devised and well adapted pattern of genetic inequality. This pattern of genetic differentiation is determined and actively maintained by selective forces: it is the population as a whole that breeds true, not its individual members. We can no longer draw a distinction between an active process of evolution and a more or less stationary end-product: evolution is constantly in progress, and the genetical structure of a population is actively, that is dynamically, sustained.

These newer ideas have important practical consequences. The older outlook was embodied in that older, almost immemorial ambition of the livestock breeder, to produce by artificial selection a true breeding stock with uniform, and uniformly desirable characteristics; and this was also the ambition—sometimes kindly, but always mistaken—of old-fashioned 'positive' eugenics. It now seems doubtful if, with free-living and naturally outbreeding organisms, such a goal can ever be achieved. Modern stockbreeders tend to adopt a very nicely calculated regimen of cross-breeding which, abandoning the goal of a single self-perpetuating stock, achieves a uniform marketable product of hybrid composition. The genetical theory underlying this scheme of breeding embodies, and was indeed partly responsible for, the newer ideas of population structure I have just outlined.

I cannot predict what new ideas will illuminate the theory of evolution in future, but it is not difficult to

guess the contexts of thought in which they are likely to appear. The main weakness of modern evolutionary theory is its lack of a fully worked out theory of variation, that is, of *candidature* for evolution, of the forms in which genetic variants are proffered for selection. We have therefore no convincing account of evolutionary progress—of the otherwise inexplicable tendency of organisms to adopt ever more complicated solutions of the problems of remaining alive. This is a 'molecular' problem, in the newer biological usage of that word, because its working out depends on a deeper understanding of how the physicochemical properties and behaviour of chromosomes and nucleoproteins generally qualify them to enrich the candidature for evolution; and this reflection is my cue to turn to conceptual advances in biology at the molecular level.

### Physical Basis of Life

In the early 1930's no one knew what to make of the nucleic acids. Bawden and Pirie had not yet shown that nucleic acid was an integral part of the structure of tobacco mosaic virus, and we were still a decade from the astonishing discovery by Avery and his colleagues, in the Rockefeller Institute, that the agent responsible for pneumococcal transformations was a deoxyribonucleic acid.

Since there was nothing very much to say about nucleic acids you may well wonder what everybody *did* talk about. One topic of conversation was the crystallization of enzymes. Sumner had crystallized urease in 1926 and Northrop pepsin in 1930; soon Stanley would crystallize tobacco mosaic virus, at that time still thought to be a pure protein. But the most exciting and, as it seemed to us, portentous discoveries were those of W. T. Astbury, whose X-ray diffraction pictures of silk fibroin and hair and feather keratins had revealed an essentially crystalline orderliness in ordinary biological structures. For some purposes, however, X-ray analysis was too powerful. The occasion called for resolving powers between those of the optical microscope and the X-ray tube, and this need was fulfilled by electron microscopy. I saw my first electron-photomicrograph in *Nature* in 1933; its resolving power was then one micron.

Electron microscopy has shown that cells contain sheets, tubes, bags and, indeed, micro-organs—real anatomical structures in the sense that they have firm and definite shapes and look as if only their size prevented our picking them up and handling them. Moreover, there is no dividing line between structures in the molecular and in the anatomical sense: macromolecules have structures in a sense intelligible to the anatomist and small anatomical structures are molecular in a sense intelligible to the chemist. (Intelligible *now*, I should add: as Pirie<sup>1</sup> has told us, the idea that molecules have literally, that is, spatially, a structure was resisted by orthodox chemists, and the credentials of molecules with weights above 5,000 were long in doubt.) In short, the orderliness of cells is a structural or crystalline orderliness—a 'solid' orderliness, indeed, for 'the so-called amorphous solids are either not really amorphous or not really solid'<sup>4</sup>.

This newer conception represents a genuine upheaval of biological thought, and it marks the disappearance of what may be called the *colloidal* conception of vital organization, itself a sophisticated variant of the older doctrine of 'protoplasm'. The idea of protoplasm as a fragile colloidal slime, a sort of biological ether permeating otherwise inanimate structures, was already obsolete in the 'thirties; even then no one could profess to be studying 'protoplasm' without being thought facetious or slightly mad. But we still clung to the colloidal conception in its more sophisticated versions, which allowed for heterogeneity and for the existence of liquid crystalline states, and it was still possible to applaud Hopkins's famous aphorism from the British Association meeting of 1913,

that the life of the cell is "the expression of a particular dynamic equilibrium in a polyphasic system". For inadequate though the colloidal conception was seen to be, there was nothing to take its place. Peters's idea of the existence of a 'cytoskeleton' to account for the orderly unfolding of cellular metabolism in time and place now seems wonderfully prescient, but there was precious little direct evidence for the existence of anything of the kind, and much that seemed incompatible with it.

The substitution of the structural for the colloidal conception of 'the physical basis of life' was one of the great revolutions of modern biology; but it was a quiet revolution, for no one opposed it, and for that reason, I suppose, no one thought to read a funeral oration over protoplasm itself.

### Cellular Differentiation in Embryonic Development

Embryology is in some ways a model science. It has always been distinguished by the exactitude, even punctilio, of its anatomical descriptions. An experiment by one of the grand masters of embryology could be made the text of a discourse on scientific method. But something is wrong; or has been wrong. There is no *theory* of development, in the sense in which Mendelism is a theory that accounts for the results of breeding experiments. There has therefore been little sense of progression or timeliness about embryological research. Of many papers delivered at embryological meetings, however good they may be in themselves—in themselves they are sometimes marvels of analysis, and complete and satisfying within their own limits—one too often feels that they might have been delivered five years beforehand without making anyone much the wiser, or deferred for five years without making anyone conscious of great loss.

It was not always so. In the 1930's experimental embryology had much the same appeal as molecular biology has to-day: students felt it to be the most rapidly advancing front of biological research. This was partly due to the work of Vogt, who had shown that the mobilization and deployment of cellular envelopes, tubes and sheets was the fundamental stratagem of early vertebrate development (thus relaying the foundations of comparative vertebrate embryology); but it was mainly due to the 'organizer theory' of Hans Spemann, the theory that differentiation in development is the outcome of an orderly sequence of specific inductive stimuli. The underlying assumption of the theory (though not then so expressed) was that we should look to the chemical properties of the inductive agent to find out why the amino-acid sequence of one enzyme or organ-specific protein should differ from the amino-acid sequence of another. The reactive capabilities of the responding tissue were emphasized repeatedly, but only at a theoretical level, for 'competence' did not lend itself to experimental analysis, and the centre of gravity of actual research lay in the chemical definition of inductive agents.

Wise after the event, we can now see that embryology simply did not have, and could not have created, the background of genetical reasoning which would have made it possible to formulate a theory of development. It is not now generally believed that a stimulus external to the system on which it acts can specify the primary structure of a protein, that is, convey instructions that amino-acids shall be assembled in a given order. The 'instructive' stimulus has gone the way of the philosopher's stone, an agent dimly akin to it in certain ways. Embryonic development at the level of molecular differentiation must therefore be an unfolding of pre-existing capabilities, an acting-out of genetically encoded instructions; the inductive stimulus is the agent that selects or activates one set of instructions rather than another. It is just possible to see how something of the kind happens in the induction of adaptive enzymes in bacteria—a

phenomenon of which the older description, the 'training' of bacteria, reminds us that it too, at one time, was thought to be 'instructive' in nature. All this applies only to biological order at the level of the amino-acid sequences of proteins or the nucleotide sequences of nucleic acids. Nothing is yet known about the genetic specification of order at levels above the molecular level.

The function performed by the hierarchy of inductive stimuli as it occurs in vertebrate development is to determine the specificities of time and place: it is an inductive stimulus which determines that a lens shall form just here and just now—not elsewhere, and at no other time. As I see it, it is the inductive process that allows vertebrate eggs and embryos before gastrulation to indulge in the prodigious range of adaptive radiation to be seen in germs as disparate as a dogfish's egg and a human being's—a case I have argued elsewhere and need not go over here again\*.

### Biology of the Organism: Animal Behaviour

If experimental embryology was the subject that seemed most exciting to students of the 'thirties, that most nearly on the threshold of a grand revelation, the study of animal behaviour (in the sense in which we now tend to use the word 'ethology'), seemed just as clearly the most frustrating and unrewarding. Twenty years later it was the other way about: embryology had lost much of its fascination and many of the ablest students were recruited into research on behaviour instead. What had happened in the meantime?

In the early 1930's we had one new behavioural concept to ponder on: the idea that an animal might in some way apprehend a sensory pattern or a behavioural situation as a whole and not by a piecing together of its sensory or motor parts. That was the lesson of *Gestalt* theory. We had also learnt finally, and I hope for ever, the methodological lesson of behaviourism: that statements about what an animal feels or is conscious of, and what its motives are, belong to an altogether different class from statements about what it does and how it acts. I say the 'methodological' lesson of behaviourism, because that word also stands for a certain psychological theory, namely, that the phenomenology of behaviour is the whole of behaviour—a theory of which I shall only say that, in my opinion, it is not nearly as silly as it sounds. Even the methodology of behaviourism seemed cruelly austere to a generation not yet weaned from the doctrine of privileged insight through introspection. But what comparable revolution of thought ushered in the study of animal behaviour in the style of Lorenz and Tinbergen and led to the foundation of flourishing schools of behaviour in Oxford, here in Cambridge, and throughout the world?

I believe the following extremely simple answer to be the right one. In the 'thirties it did not seem to us that there was any way of studying behaviour 'scientifically' except through some kind of experimental intervention—except by confronting the subject of our observations with a 'situation' or with a nicely contrived stimulus and then recording what the animal did. The situation would then be varied in some way that seemed appropriate, whereupon the animal's behaviour would also vary. Even poking an animal would surely be better than just looking at it: that would lead to anecdotalism: that was what bird-watchers did.

Yet it was also what the pioneers of ethology did. They studied natural behaviour instead of contrived behaviour, and were thus able for the first time to discern natural behaviour structures or episodes—a style of analysis helped very greatly by the comparative approach, for the occurrence of the same or similar behavioural sequences in members of related species reinforced the idea that there was a certain natural connectedness between its various terms, as if they represented the

playing out of a certain instinctual programme. Then, and only then, was it possible to start to obtain significant information from the study of contrived behaviour—from the application or withholding of stimuli—for it is not informative to study variations in behaviour unless we know beforehand the norm from which the variants depart.

The form of address 'project and development' belongs to the four levels of hierarchy in the service of the major dev- In the recent growth of 'beliefs' belonging to the 'no opportunity' of modern 'of bodily con- of the material' anything except 'functions of' ough of the 'some morals, 'behaviour—in par- 'mental approach—' 'ments in the Baconian' of contriving 'experiences' 'our general store of empirical' to sustain or confute a specific 'opposition. ## BONE METABOLISM INFERRED FROM FALL-OUT INVESTIGATION

By J. RIVERA

Health and Safety Laboratory, U.S. Atomic Energy Commission, New York

From nuclear weapons tests has contaminated human diet and resulted in the accumulation of  $^{90}\text{Sr}$  in the skeleton. Measurements of  $^{90}\text{Sr}$  levels in the diet made over several years enable us to draw inferences as to the level of strontium and to predict changes in concentrations resulting from changes in diet variations.

Monthly measurements of the  $^{90}\text{Sr}$  content of food in the New York City area have been made at the Health and Safety Laboratory. In addition to measurements, starting in 1960 analyses for  $^{90}\text{Sr}$  in other composite foods purchased in New York City, such as meat, canned vegetables, etc., have been made at this laboratory<sup>1</sup>. Based on the results of more than 400 analyses, estimates have been made of the yearly  $^{90}\text{Sr}$  contamination of the diet in New York since 1954. These estimates are shown in Fig. 1. The  $^{90}\text{Sr}$  concentration of bone due to dietary  $^{90}\text{Sr}$  levels can be expected, since each year of bone mineral is replaced by minerals from the diet. In adult bone there is essentially no net loss or diminution in bone, hence the amount of  $^{90}\text{Sr}$  at each year must be equal to that gained. As the total calcium in bone does not change from year to year in adults, an equation expressing the changes in concentrations in bone with changes in  $^{90}\text{Sr}$  intake

$$B_n = 0.975B_{n-1} - f \cdot 0.975B_{n-1} + f K Z_{n-1} \quad (1)$$

is the  $^{90}\text{Sr}/\text{Ca}$  ratio of bone at the beginning of year 'n',  $B_{n-1}$  is the  $^{90}\text{Sr}/\text{Ca}$  ratio of the bone at the beginning of year 'n-1',  $f$  is the fraction of the bone turned over during the year 'n-1',  $K$  is the ratio of  $^{90}\text{Sr}/\text{Ca}$  in the bone to that in the diet (observed ratio)<sup>2</sup>,  $Z_{n-1}$  is the  $^{90}\text{Sr}/\text{Ca}$  ratio of the diet during year 'n-1'. The factor 0.975 is introduced to account for the radioactive decay of  $^{90}\text{Sr}$  in one year.

Various investigations have shown that the observed ratio ( $K$ ) for adults is about 0.25 (ref. 3). Rates of turn-over rates for different bones have been made. Liniecki<sup>4</sup>, using the data of Kulp and his co-workers<sup>5</sup>, found that the  $^{90}\text{Sr}$  concentrations in total adult skeleton in New York City (1954-58), estimated the turn-over rate of the skeleton to be about 3.5 per cent per annum by the method which is independent of the observed rate. Bryant and Loutit<sup>6</sup> have estimated that the rate of vertebrae is about 8 per cent per annum and the mid-shafts of femora is about 1.5 per cent per annum. Using the same method, involving specific activity ( $^{90}\text{Sr}/\text{mg Sr}$ ) measurements in diet and bone, we have found substantially these same turn-over rates for vertebrae and femur shafts<sup>7</sup>.

Fig. 1. The yearly strontium-90 content of the diet in New York. —, Estimated; —, measured; . . . , predicted.

### Radiation Damage in Graphite

J. H. W. Simmons, *Atomic Energy  
Research Establishment, Harwell*

**Partial Contents:** Introduction; The Wigner effect; The displacement of atoms by neutrons and fast charged particles; The displacement of atoms by high energy nuclear particles, electrons and heavy charged particles—fast neutrons; Defect structures in irradiated graphite; The use of diffraction to study radiation defects; The effect of irradiation on the electrical and magnetic properties of graphite; The effect of irradiation at low temperature; The effect of irradiation on the thermal and structural properties of graphite; The thermal conductivity of graphite; graphite.

International Series of Monographs  
in Nuclear Energy, Volume 102

258 pages/May 1966 80s./\$15.00

### Higher Algebra—Linear Algebra, Polynomials, General Algebra

A. P. Mikhlin and I. V. Proskuryakov

**Partial Contents:** Determinants and systems of linear equations; Elementary properties of determinants; Symmetric, skew-symmetric and pseudo-symmetric determinants; Cramer's rule; The rank of a matrix; Matrices and quadratic forms; Matrix polynomials; Jacobian matrices; Positive definite quadratic forms; The algebra of polynomials; Horner's scheme; Location of the roots of polynomials—the decomposition of polynomials into factors; Criteria of stability; General algebra; Homomorphism; Abelian groups; Lattices; Boolean algebras.

International Series of Monographs  
in Pure and Applied Mathematics,  
Volume 80

286 pages/October 1965 60s./\$9.50

### Elements of Probability Theory

L. Z. Rumshitskii

**Contents:** Events and probability; Random variables and probability distributions; Numerical characteristics of probability distributions; The law of large numbers; Limit theorems and estimates of the mean; Applications of probability to the theory of observations; Linear correlation.

172 pages/November 1965 35s./\$5.50

### The Spiral After-effect

H. C. Holland, *Lecturer in  
Psychology, University of London*

**Contents:** Introduction and historical review of studies investigating or using the illusion; A brief outline of selected stimulus variables and their influence on the incidence and duration of the after-effect; An outline of some of the programme variables relevant to the incidence and duration of the illusion; An outline of the influence of selected observer variables on the incidence and duration of the after effect; Scoring the illusion; Some theoretical explanations of the after-effect; Appendix 1. An abstract of Wohlgemuth's major finding and conclusions concerning his own and earlier work; Appendix 2. An annotated bibliography of the major works and findings since 1914; Appendix 3. Reproductions of some useful spirals.

International Series of Monographs  
in Experimental Psychology—  
Volume 2.

144 pages/November 1965 35s./\$6.00

### Science, Industry and the State

*Proceedings of a Symposium held at  
the Royal Society of Health*

Edited by G. Teeling-Smith, *Director,  
Office of Health Economics, London*

This book is based on a series of six lectures discussing some of the special considerations which arise when a science-based industry has the government as a major customer in its home market.

**Contents:** The influence of patents on the pattern of progress—G. R. Fryers; The economics of research-based industry—F. M. Lee; The role of marketing in scientific progress—G. Teeling-Smith; The international pattern of pharmaceutical research—J. Yule Bogue; Government relations with a research-based industry—C. S. Jones; Where does the public interest lie?—M. E. Beesley.

104 pages/October 1965 21s./\$3.50

### The International Journal of Applied Radiation and Isotopes

The object of this journal is to provide a medium for the publication of isotope and radiation techniques, especially novel ones and those capable of wide application.

**Partial Contents of a recent issue:** M. S. Elmanharawy—Experimental comparison of dosimetric data for yttrium oxide ( $Y^{90}$ ) rods; J. S. Lee, M. A. Shiflett and R. O. Sinnhuber—Radiation pasteurization of seafood. The combined effect of sodium benzoate and irradiation for retarding microbial growth in Dover sole; B. L. Campbell and W. R. Ellis—The development of oil-soluble gold-198 compounds for industrial radiotracing; M. F. Abdel-Wahab and S. A. El-Kinawy—Preparation of radioiodinated serum albumin and radioiodinated egg albumin by gel filtration; K. Samsahl, D. Brune and P. O. Wester—Simultaneous determination of 30 trace elements in cancerous and non-cancerous human tissue samples by neutron activation analysis.

# Academic Press

with 7 Distinguished Journals

## DEVELOPMENTAL BIOLOGY

managing editor: M. V. Edds, Jr.

Publishes articles bearing on problems of development in the broadest sense. It will contain papers dealing with embryonic and postembryonic development, growth, regeneration, and tissue repair, of both plants and animals.

Volumes 13-14 (Bimonthly) 1966, 128s. 6d. per volume, 257s. per year.  
 1s. 2d. postage outside U.S.A.  
 10 copies available upon request

## THEORETICAL BIOLOGY

chief editor: J. F. Danielli

Principal publishing medium for theoretical work in all fields of biology. Includes papers on generalized theories, theories of specific processes or phenomena, theoretical discussion of specific projects, and theoretical discussion of methods.

Volumes 10-12 (Bimonthly) 1966, 115s. per volume, 345s. per year.  
 1s. postage  
 10 copies available upon request

## CELLULAR AND MOLECULAR PATHOLOGY

editor: Frederick Coulston and Wilbur A. Thomas

Publishes manuscripts on disease processes in general, with emphasis on structural and biochemical alterations in mammalian tissues and fluids. Of particular interest are papers that apply the newer techniques of analytical chemistry, chemistry, pharmacology, toxicology, and electron microscopy to problems of pathology in man and animals.

Volumes 5 (Bimonthly) 1966, 186s.  
 1s. 3d. postage outside U.S.A.  
 10 copies available upon request

## ADVANCES IN COLLOID AND INTERFACE SCIENCE

editors: Milton Kerker and A. C. Zettlemoyer

Publishes original papers, letters and book reviews in colloid and interface science.

Volumes 21-22 (Monthly) 1966, 128s. 6d. per volume, 257s. per year.  
 15s. 8d. postage outside U.S.A.  
 10 copies available upon request

## ADVANCES IN CATALYSIS

editors: J. H. de Boer and P. W. Selwood

Publishes articles dealing with original studies in heterogeneous and homogeneous catalysis as well as studies relating catalytic properties with chemical processes at surfaces, studies of the chemistry of surfaces, and engineering studies related to catalysis.

Volumes 5-6 (Bimonthly) 1966, 143s. per volume, 286s. per year.  
 15s. 8d. postage outside U.S.A.  
 10 copies available upon request

## TOXICOLOGY AND APPLIED PHARMACOLOGY

edited by C. Boyd Shaffer

Journal of the Society of Toxicology

Deals with alterations in tissue structure and function resulting from the administration of chemicals, drugs, and natural poisons to animals and man. Emphasis is placed, where possible, on the applicability of the results to an evaluation of human toxicity.

Volumes 8-9 (Bimonthly) 1966, 143s. per volume, 286s. per year.  
 28s. 7d. postage outside U.S.A.  
 10 copies available upon request

## ADVANCES IN INVERTEBRATE PATHOLOGY

editor-in-chief: Edward A. Steinhaus

Publishes articles and notes on all aspects of original research concerned with the nature and study of microbial and parasitic diseases of invertebrates, the suppression of these diseases in beneficial invertebrates, their use in the control of invertebrate pests, and those phases of general invertebrate microbiology that may have some relation to disease in vertebrate animals.

Volume 8 (Quarterly) 1966, 178s. 6d.  
 17s. 10d. postage outside U.S.A.  
 10 copies available upon request

With the co-operation of the New York Medical Examiners Office, this laboratory has obtained over the past four years for  $^{87}\text{Sr}$  analyses more than 400 specimens of human vertebrae from victims of accidents. In addition, about 60 specimens of long bone shafts from osteogenic sarcoma victims obtained through the co-operation of Dr. H. Q. Woodard of the Sloan Kettering Institute were analysed for  $^{87}\text{Sr}$  (ref. 8). The results of the analyses of these bone specimens provide data to evaluate the accuracy of previously estimated bone turn-over rates.

Equation 1 was used to calculate  $^{87}\text{Sr}$  concentrations in vertebrae ( $V$ ) and femur shafts ( $F$ ) assuming the turn-over rates for these bones were 8 and 1.5 per cent per annum respectively. In addition, calculations of the  $^{87}\text{Sr}$  concentrations in the skeleton ( $S$ ) for New York City residents using a turn-over rate of 3.5 per cent per annum were made for the period 1954-64. The results of these calculations together with observed values are shown in Table 1.

Table 1. CALCULATED AND OBSERVED PROPORTIONS OF STRONTIUM-90 PER GRAM OF CALCIUM IN VERTEBRAE, FEMUR SHAFTS, AND SKELETONS OF NEW YORK CITY ADULTS

\* Calculated using equation 1.

† Calculated from  $V$  observed divided by 2.

The agreement between calculated and observed results indicates that equation 1 can be used to predict changes in  $^{87}\text{Sr}$  concentrations in bone and that the turn-over rates of vertebrae, femur shafts, and whole skeletons previously estimated are quite reasonable.

However, equation 1 implies that there is a single exponential law of excretion of strontium from bone. Since the skeleton comprises bones of different turn-over rates the assumption of a single turn-over rate for it must be only approximately valid.

From the work of Bryant and Loutit it would appear that the skeletal components with fastest and slowest turn-over rates are vertebrae and femur shafts respectively. It seemed reasonable, therefore, to attempt to describe the excretion of strontium from the skeleton as a combination of excretion from a vertebrae-like component and a femur-shaft-like component.

If  $W$  is the total amount of mineral in the skeleton,  $X$  is the amount of mineral in the vertebrae-like component, and  $Y$  the amount in the femur-shaft-like component, then:

$$W = X + Y$$

The amounts of mineral excreted each year from each component are  $f$  times the amount initially present. Hence:

$$0.035 W = 0.080 X + 0.015 Y$$

Solving these equations simultaneously, we find:

$$X/W = 0.3 \quad Y/W = 0.7$$

The skeleton can, therefore, be thought of as consisting of three-tenths vertebrae-like bone and seven-tenths femur-shaft-like bone. If this is the case, then:

$$S = 0.3 V + 0.7 F \quad (2)$$

where  $S$  is the  $^{87}\text{Sr}/\text{Ca}$  ratio of the skeleton and  $V$  and  $F$  are the  $^{87}\text{Sr}/\text{Ca}$  ratios of vertebrae and femur shafts, respectively. Calculations of  $S$  using equation 2 are listed in Table 1.

By comparing observed and calculated results in Table 1 it is evident that equation 1 has adequately described the

variation of vertebrae, femur shaft and skeletal  $^{87}\text{Sr}$  concentrations with time in the past and, therefore, probably provides a basis for predicting future  $^{87}\text{Sr}$  concentration in these bones. The skeletal  $^{87}\text{Sr}$  concentrations calculated by using equation 1 or 2 are similar. But, as can be seen, this similarity does not persist. The ratios of  $^{87}\text{Sr}$  concentrations in vertebrae to total skeleton have been about two and those of femur shafts to total skeletons have been about one-half. These ratios have remained remarkably constant. As Lindecki has indicated, these ratios should change only very slowly with time and, therefore, future estimates of skeletal  $^{87}\text{Sr}$  concentrations can be made by determining the  $^{87}\text{Sr}/\text{Ca}$  ratio of vertebrae and dividing by two ( $V/S$ ) or by measuring the  $^{87}\text{Sr}/\text{Ca}$  ratio of femur shafts and dividing by  $F/S$ , that is, one-half.

The average  $^{87}\text{Sr}/\text{Ca}$  ratio of the diet in New York City ( $Z$ ) has been related to the cumulative deposit of  $^{87}\text{Sr}$  in the soil ( $D$ ) and to the fall-out rate experienced during the year ( $R$ ) in the following way:

$$Z = 0.1 D + 0.2 R$$

where  $Z$  is in  $\mu\text{g}/\text{g}$  Ca,  $D$  is in  $\text{mc./mile}^2$  and  $R$  is in  $\text{mc./mile}^2/\text{yr.}$

From estimates of expected fall-out rates for the next nine years provided by Volchok<sup>9</sup>, values of  $Z$  were calculated and used with equations 1 and 2 to predict vertebrae, femur shaft, and total skeletal  $^{87}\text{Sr}$  concentrations. These results are shown in Table 2. The estimated average dose to the skeletons of New York City residents by the end of 1964 from  $^{87}\text{Sr}$  was 8.6 millirads. By 1974 the average accumulated dose will be about 60 millirads. Doses received by vertebrae will be about twice this amount while those to femur shafts will be about half as great. These estimates are probably high since no account has been taken of the lesser availability of  $^{87}\text{Sr}$  in the soil to plants with time, which would cause the diet (and bone-levels) to decrease somewhat faster than has been assumed.

\* Assuming no further atmospheric tests of nuclear weapons.

† Calculated using equation 2.

The dose rate to bone from natural background radiation has been estimated to be about 130 mrad/yr<sup>10</sup>; in the period 1954-64 the dose to bone from background would be 1,300 mrad and from 1954-74 the dose would be 2,600 mrad. It is evident, therefore, that the radiation dose to bone from  $^{87}\text{Sr}$  has been negligible compared with that from natural background.

$^{87}\text{Sr}$  from nuclear weapons tests has provided a tracer material which can be used to examine mineral metabolism for individuals of all ages. In the adult it appears that the turn-over rate of the vertebrae-like component of the skeleton is 8 per cent per annum while that for the femur-shaft-like component is 1.5 per cent per annum. The total skeleton can be thought of as consisting of 30 per cent vertebrae-like bone and 70 per cent femur-shaft-like bone. In the adult these turn-over rates as well as the bone diet  $^{87}\text{Sr}/\text{Ca}$  observed ratios do not appear to change. In children, however, it is known that this is not the case. For example, in the very young (< two years old) the diet bone observed ratio  $\bar{X}$  is greater than 0.25 and may approach 1.0 during the first month of life and the turn-over rate may also approach 1.0 during early infancy<sup>11</sup>. Investigations, now in progress in this laboratory, of the changes in  $^{87}\text{Sr}$ -levels in bone with changes in dietary

may provide new information on the rate of bone mineral metabolism of individuals twenty years of age. Kletzing for help in the calculations and J. S. E. Kelley for the preparation and plates.

# AL OF PUMICE, SUPPOSEDLY FROM THE 1962 SOUTH SANDWICH ISLANDS ERUPTION, ON SOUTHERN AUSTRALIAN SHORES

By F. L. SUTHERLAND  
Queen Victoria Museum, Launceston, Tasmania

Strandings from external eruptions are fairly common along Australian shores. One of the first was that of Clarke<sup>1</sup> in 1842, who remarked: "The range of this drift pumice along the coast of Australia and Tasmania would not be an employment". Generally, however, there have been little work done in this connexion. Considerable quantities of pumice were washed ashore on the coasts of Australia. The arrival of the first pumice on the Tasmanian coast was recorded by me<sup>2</sup>. It was noted that the pumice was a remnant of the large eruption from a submarine eruption near the South Sandwich Islands in March 1962 (ref. 3). Strandings of pumice along the coast of the South Sandwich Islands at time-intervals consistent with the drift of pumice towards the West Wind Drift have been recorded from Bouvet Island<sup>4</sup>, Heard Island<sup>5</sup>, and Macquarie Island<sup>6</sup> (K. G. Simpson, personal communication). The geological and oceanographical aspects of the South Sandwich Islands eruption are being examined by Adie, University of Birmingham. This article reports the results of further examination of the pumice washed up on southern Australian shores during 1964-65, and its dispersal. The specimens referred to are collections of the Queen Victoria Museum.

## The Pumice

The pumice, as found washed up, is commonly rounded and encrusted with marine growth, mainly algae (*Lepas*) and algae. The pieces vary in size, rarely greater than 1 ft. across. Most of the pieces are uniform whitish-grey in colour, but some, particularly from Western Australia, show colour variations from whitish to dark grey. A number of specimens of small xenoliths of olivine basalt, the largest being 7 cm x 6 cm x 4 cm in size.

A general petrological description of the pumice washed up on Tasmania has already been given<sup>7</sup>. Macroscopically the pumice from Australian strandings is closely similar in appearance to a sample from the original South Sandwich Islands raft and to samples stranded on Heard and Macquarie Islands in 1963.

In thin sections the pumice consists of vesicular glass containing crystals of plagioclase, hypersthene, clinopyroxene; lesser amounts of quartz, magnetite, hornblende; a little biotite, and rare small crystals of apatite and sphene. The plagioclase is andesine-labradorite in composition and the crystals are mainly euhedral. A few enclose a core pitted and riddled with generally elongate inclusions of glass (?). The hypersthene is pleochroic with X yellowish brown, Y pale yellow, Z pale green, and has a 2V<sub>a</sub> of about 50°-60°. The clinopyroxene shows a ZAC extinction angle of 40°, a 2V<sub>γ</sub> of about 60°, and is weakly pleochroic from pale brown to pale green. It is ferroan diopside or augite. The proportions of the two pyroxenes vary and they occur both as separate crystals and in association, mainly in parallel intergrowth. The hornblende and biotite appear to have formed from late magmatic alteration of the pyroxenes. The quartz occurs mainly as sporadic clusters of deeply embayed phenocrysts, up to 1.5 mm across.

The pumice shows petrological similarities with the description of the South Sandwich Islands material<sup>8</sup> in the size and relative abundances of the plagioclase and pyroxene phenocrysts and in the twinning, zoning, and composition of the plagioclase. It differs in the presence of ferroan diopside, corroded quartz, hornblende and biotite. However, I was able to observe both the first two features in thin sections of pumice samples from the South Sandwich Islands raft and from Heard Island. A comparison of the mineralogy of pumice samples from Australian localities, from the South Sandwich Islands, and from Heard Island is given in Table 1.

COMPARISON OF THE MINERALOGY OF THE CRYSTALS CONTAINED IN PUMICE SAMPLES FROM AUSTRALIA, HEARD ISLAND, AND THE SOUTH SANDWICH ISLANDS

Locality	Trial Harbour, W. Tasmania	Maatsuyker Is. S. Tasmania	D'Entrecasteau Pt. W. Australia	City Beach, Perth, W. Australia	Heard Is.	South Sandwich Islands
Plagioclase	Andesine-labradorite	Ditto	Ditto	Ditto	Ditto	Ditto
Quartz	Present	Ditto	Ditto	Ditto	Ditto	Ditto
Hypersthene	Carlsbad, Albite	Ditto	Ditto	Ditto	Ditto	Ditto
Pyroxene	Some crystals with cores riddled with glass inclusions	Ditto	Ditto	Ditto	Ditto	Ditto
Pyroxene	Hypersthene, pleochroic	Ditto	Ditto	Ditto	Ditto	Ditto
Pyroxene	Ferroan diopside, weakly pleochroic	Ditto	Ditto	Ditto	Ditto	Ditto
Pyroxene	Present, corroded	Ditto	Ditto	Ditto	Ditto	Ditto
Biotite	Present	Ditto	Ditto	Ditto	Ditto	Ditto
Apatite	Present	Present	Present	Absent	Absent	Absent
Sphene	Present	Present	Absent	Present	Absent	Absent

The glass in Australian samples has largely altered to palagonite and anisotropic breakdown products, thus making accurate determinations of its refractive index difficult. Chemically, the pumice shows the same low potash content and low potash/soda ratio of the South Sandwich Islands material (Table 2).

### Source of the Pumice

The close match, both petrologically and chemically, of the pumice with that of the South Sandwich Islands eruption indicates it is a remnant of the original raft ejected in 1962. Data, given later, on the dispersal of the pumice in Australian waters indicate a south-westerly derivation, also supporting this correlation. A submarine eruption to the south-west of Australia, distinct from the 1962 South Sandwich Islands eruption, but which ejected a similar type of pumice, is a further possibility. I am unaware of any reports of such an eruption, and this is considered to be unlikely. Another possible source which must be considered, however, is the eruption of Mt. Agung, Bali, on March 17, 1963. In her eye-witness account of the eruption, Matthews<sup>4</sup> describes the ejection of ash, sand and volcanic bombs, but not pumice specifically. Although not a scientific document, her writings make it clear that she was well acquainted with the nature of pumice. M. M. Purbo Hadiwidjojo, Geological Survey of Indonesia, has also informed me that no pumice was found following the eruption of Mt. Agung. There remains the remote possibility that pumice was ejected during the explosive eruption with sufficient violence to carry it out to sea without any falling on land. Chemical analyses of lapilli and ash deposits from Mt. Agung (supplied by M. M. Purbo Hadiwidjojo) are similar to analyses of the Australian pumice (Table 2) in having low potash contents and low potash/soda ratios, but in all cases the soda contents are somewhat lower. An analysis showing the highest soda content determined for the eruptive products of the Mt. Agung eruption is shown in Table 2. It would seem, then, that it is unlikely this eruption was the source of the pumice. This is further substantiated by the recovery of small balls of pumice apparently identical with that of the Australian strandings, from the stomachs of fledgling mutton birds on March 29, 1963, in Bass Strait<sup>5</sup>. It is highly improbable that pumice erupted from Bali on March 17, 1963, could have drifted far enough in 12 days to be picked up by mutton birds nesting almost 4,000 miles to the south-west.

### Dispersal of the Pumice

The following account of the dispersal of the pumice in southern Australian waters is based on numerous reports of strandings received by me during 1964 and early 1965. In nearly every case a specimen of pumice was forwarded enabling its identity to be checked. All the samples of pumice, with one exception from the coast of New South Wales, are of similar nature and were presumably derived from the one source, considered to be the South Sandwich Islands raft. It must be pointed out that the reported date of finding of stranded pumice is not necessarily the date of arrival.

From all available reports the first pumice strandings appear to have occurred on the west coast of Tasmania in late December 1963 or at the beginning of January 1964. Pumice was found on the south-west coast of King

Island in mid-January, showing it had reached western Bass Strait by this time. It was first reported from the south coast of Tasmania in February, from the east coast in May, and from the north coast in late August. No pumice strandings were observed by me during a visit to Flinders Island, eastern Bass Strait, in mid-April. The earliest record of the pumice on the mainland of Australia is late April at Port Campbell, Victoria. These reports suggest the pumice arrived from west, rather than east of Tasmania.

The current flows in Tasmania differ in summer and winter (Fig. 1). This has been demonstrated by a recent drift bottle programme<sup>6</sup> and is supported by a scrutiny of the earlier drift bottle data of Russell<sup>8-14</sup>. The winter flow is eastwards and southwards, and reverses in the summer, setting westerly and northerly. The arrival of the pumice on the west coast of Tasmania by January in terms of the summer flow suggests the pumice was carried up from the south-west. This is compatible with the pumice being part of the South Sandwich Islands raft. Weather conditions experienced at this time also would greatly assist the currents in driving the pumice ashore on Tasmania. The local meteorological report for January<sup>15</sup> states: "Rarely has a mid-summer blasted Tasmania with the westerlies like the period December 25, 1963-January 28, 1964. The scale and duration of low pressure systems affecting the State was extreme—only occasionally in some winters does this occur". Reported sighting of pumice washing ashore during the later half of January and early February suggest a southward drift down the west coast of Tasmania. It is possible that the abnormal

Fig. 1. Drift of surface water in Tasmanian and Victorian waters in summer and winter (after ref. 7)

; January caused a brief anomalous reversal in flow to winter flow as occurred in the 59-60 (ref. 7).

current flows and prevailing weather explain the absence of any pumice strandings until the beginning of 1964, although the South Sandwich Islands raft would be to the south, probably in April or May 1963. Migration of the pumice would be inhibited by the current flow then operating. Furthermore, the weather systems exercised a dominant influence on the weather during the autumn from late July to early August, greatly reducing the severity of the 19-20. Most of August was also quieter than the marked absence of strong west winds<sup>10</sup>.

to compare the arrival of the pumice on a like stranding on New Zealand. Here, as the first strandings appear to have occurred after the passage of the front of the South Sandwich Islands raft to the south. The pumice was on Stewart Island off the south coast in 1963. Large quantities of pumice came ashore at Mason Bay, which faces due west, and a washing up at the end of March 1964 (Watters, personal communication). Dr. Watters informed me that Stewart Island experienced gale-force south-westerly winds over the winter of 1963. The front of the South Sandwich Islands raft reached Macquarie Island by June 1963, so that during the winter and spring 1963 it was positioned less than 500 miles to the south. The marked effect of pressure on the drift of floating objects in the Southern Ocean is a fact that the pumice was not blown ashore until November suggests a mitigating effect.

The arrival of the pumice on Stewart Island all have resulted from a reversal in October of current flow, south-west of New Zealand, been shown to occur about this time in Tasmania. There are comparatively few data at this point, but it is perhaps significant that the survey of the coastal currents of New Zealand in summer and autumn releases off the south coast recovered but no winter and spring releases. A later date of the pumice strandings compared to Stewart Island can be accounted for by the northerly latitude of

number of pieces of pumice covered with recent marine growth, washed up on the beaches during a visit to the west coast of Tasmania in August. These observations indicate a further influx of pumice into southern Australian waters associated with the winter current flows. It is considered that the pumice was brought in on the strong north-easterly indraft of the West Wind Drift which impinges on the south-western corner of Australia<sup>11-14</sup>: the main body of the South Sandwich Islands raft having by this time dispersed sufficiently far northwards to be tapped. This current breaks against the Australian continent, forming branches that sweep the west and south coasts, and these would carry the pumice northwards and eastwards respectively. The extent of the northward drift is not well known, but eastwards the pumice was passing through Bass Strait and also washing up on the west coast of Tasmania by July. The influx of pumice on these currents was probably checked somewhat with the establishment of the summer flows, as the beaches near Fremantle, Western Australia, were bare of pumice in November (G. Smith, personal communication).

During January 1965 pumice gravel was observed washing up on the southern coast of Western Australia at Denmark. By March, strand lines on the beaches between Denmark and Cape Leeuwin were well marked with fine granular pumice with only an occasional larger piece, and there were quite large banks of this material west of D'Entrecasteau Point (G. Kendrick, personal communication). Small pumice pieces were also being stranded on the east coast of Tasmania in early March 1965 above Cape Bougainville where there was no pumice washing ashore in late January 1965 (M. Olsen, personal communication). These strandings are interpreted as resulting from the passage of the dispersed 'tail' of the South Sandwich Islands raft. In the eastward drift of the raft across the Southern Ocean the larger pieces of pumice would be more subject to assisting wind pressures and the finer material would tend to lag behind at the tail end. Calculations based on the date of the arrival of pumice on Macquarie Island indicate the front of the raft covered the 8,000-mile journey at an average speed of approximately 18 miles/day. Such a speed has been recorded for a drift bottle that covered 1,250 miles in the Southern Ocean<sup>15</sup>, but the maximum average speed recorded by bottles that have covered 8,000 miles is about 12 miles/day<sup>16</sup>. This suggests that the larger pumice pieces were more responsive to wind assistance than drift bottles. With the foregoing speed it would seem that the front

strandings on the mainland were reported from many points along the southern coast (Fig. 2). Presumably some of the pumice also drifted up on to the east coast of the continent as the data of Russell<sup>17-19</sup> show a number of cases of northward drift of cases of northward drift of the southerly sweep of the Australian Current. Strandings reported from the west coast north as Wedge Island. Noticeable amounts of pumice were reported washed up on the beaches of Western Australia on the onset of the weather about the middle of the most northerly stranding in August, but had arrived a bit earlier. Counts of pumice were also being taken up on the Southern Ocean coast near Robe in June; Sydney, Victoria, in late June; Furneaux Islands, eastern Tasmania in mid-July. I also noted a

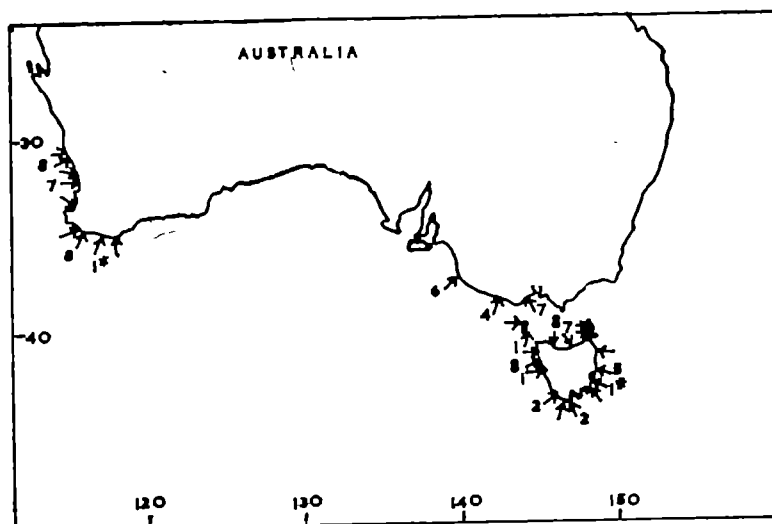

Fig. 2. Reported localities of the pumice strandings on the southern Australian coast, 1964-65. The figures indicate the month in which the strandings were first reported or the month of later fresh arrivals. For strandings taking place in 1965 the monthly figure is marked with an asterisk.

of the raft, provided there had not been complete dispersion or sinking due to water logging, circumnavigated the Southern Ocean by the time the 'tail' of the raft passed Tasmania in early 1965. This gives an idea of the extent of the longitudinal dispersion of the raft under the influence of the West Wind Drift from the time of its first sighting in March 1962, when it covered a degree and a quarter of longitude\*. The average drift speed of the fine pumice gravel which appears to form the 'tail' of the raft, based on its arrival on Australian shores, is about 6-7 miles/day. This agrees quite well with the speed of 8 miles/day quoted by Deacon<sup>17</sup> for the drift of objects in the West Wind Drift lying more or less awash and presumably not greatly assisted by wind pressures.

### Ornithological Implications

The recovery of pumiceous balls, mentioned earlier, from mutton bird (*Puffinus tenuirostris*) fledgelings in Bass Strait in late March 1963 (ref. 2) is of ornithological interest. The balls were found in the stomachs of fledgelings on Big Dog Island in the Furneaux Group on March 29. On examination the pumice balls appear to be petrologically identical with the pumice stranded on southern Australian coasts in 1964, and chemically show the same potash and soda content (Table 2). The Australian strandings are correlated with the South Sandwich Island raft, and knowledge of the position of the raft at the time of recovery of the pumiceous balls from the fledgelings should give information on the feeding range of the parent birds.

The front of the South Sandwich Islands raft apparently reached Macquarie Island in June 1963. Barber, Dedswell and Ingle<sup>22</sup> record that: "A message bottle dropped about 1,250 miles to the east of Macquarie Island was recovered from that Island 10 weeks later". This gives a surface drift speed of at least 18 miles/day, which is also the average drift speed previously determined for the front of the South Sandwich Islands raft. Calculations based on these data suggest that at the time of the recovery of the pumiceous balls from the fledgelings in Bass Strait, the front of the raft was, at least, about 1,200 miles west of Macquarie Island. The raft was presumably not farther north than latitude 47° S., as shown by the absence of strandings on Tasmania and Stewart Island until several months after the front of the raft crossed these longitudes.

On this basis the parent mutton birds must have flown about 1,000 miles to the south-west of their breeding ground to have picked up the pumice. Even if allowances are made for a possible over-estimation of the drift speed of the pumice raft in the milder than normal westerly spring weather of 1963, a conservative estimate suggests a south-westerly flight of at least 500 miles. Pumiceous

balls were again recovered from mutton bird fledgelings on Bass Strait Islands in the following breeding season in 1964 (M. Olsen, personal communication), but by this time pumice had drifted into Tasmanian waters. Other cases of sea-birds, notably the albatross, picking up floating pumice were observed at Macquarie Island in 1963 (K. G. Simpson, personal communication) and at Heard Island (P. J. Stephenson, personal communication) in 1933.

I thank the numerous persons who sent in reports and specimens of the drift pumice and generally assisted in making this compilation possible. In particular I acknowledge the assistance of Dr. W. A. Watters, New Zealand Geological Survey, for a sample of the original South Sandwich Islands pumice and information of the New Zealand strandings; of Dr. N. H. Fisher, Bureau of Mineral Resources, Australia, for specimens and information on pumice strandings on Heard Island; of Mr. M. M. Purbo Hadidwidjojo, Geological Survey of Indonesia, for information on the eruption of Mt. Agung, Bali; of Mr. K. G. Simpson, C.S.I.R.O., Australia, for information and pumice samples from Macquarie Island; of Mr. M. Olsen for oceanographical information; of Mr. W. St. C. Manson, Tasmanian Department of Mines, in regard to chemical analyses; of Messrs. D. Merilees and G. Kendrick, Western Australian Museum, for samples and information of Western Australian strandings; of Mr. R. Both, Tasmanian Museum, for thin sectioning of pumice samples; and of Mr. W. F. Ellis, director, Queen Victoria Museum, for his advice.

## NEWS and VIEWS

### Electronic and Electrical Engineering in the University of Birmingham

E. D. R. SHEARMAN, senior lecturer in the Department of Electronic and Electrical Engineering in the University of Birmingham, has been appointed to an additional chair in that Department. The new chair is being established from October 1, 1965, as a result of the continued growth of the Department of Electronic and Electrical Engineering. There will thus be four professors in this Department; the others are Prof. D. G. Tucker (head of Department), Prof. J. T. Allanson and Prof. H. A. Prime. The Department will soon be moving to a new building and already has nearly 120 graduate workers and staff in addition to the undergraduate students.

Prof. E. D. R. Shearman

MR. SHEARMAN graduated with first-class honours in electrical engineering from the Imperial College of Science and Technology in 1945. He was awarded four Premiums from the Institution of Electrical Engineers for outstanding merit in his publications. From 1945 until 1947 he worked with the Admiralty on naval communications, and from 1947 until 1961 at the Radio Research Station, Slough, on radio propagation and ionospheric research. During 1960 he spent six months in Canada assisting in the design of the *Alouette* topside-sounder satellite. Since 1961 he has been senior lecturer in electromagnetism in the University of Birmingham, where he has built up an active research group in communication systems. He

number of Government and professional

Mathematics in the University of Newcastle  
Prof. A. Jeffrey

Dr. J. H. Jeffery, senior mathematician in the Advanced Laboratories at Rolls-Royce Ltd., has been appointed to the newly established chair of engineering at the University of Newcastle upon Tyne. Dr. Jeffery is thirty-six years of age, and was educated at the Grammar School, Croydon Polytechnic, and the University of London, from which he received his Ph.D. degree in 1953. From 1953 until 1956 he was engaged in guided-missile problems in the research department of the General Electric Co. In 1956 he joined Rolls-Royce Ltd., and was engaged initially on mathematical problems which arose in the design of nuclear reactors for submarine propulsion. Later on, he became a senior mathematician in the Company's Advanced Laboratories, and during this period he spent a year in the Magneto-Fluid Dynamics Division, of the University of the State of New York, working under the direction of Prof. H. Grad. Dr. Jeffery also co-operated with T. Taniuti from the University of Tokyo, in the preparation of a book on *Nonlinear Wave Propagation*. Dr. Jeffery's research has been the study of nonlinear partial differential equations and, in particular, a detailed study of the appearance and propagation of discontinuities in solutions. He has applied this work to a wide variety of different physical problems to illustrate the physical interpretation of the mathematical phenomena. He took up his new appointment in 1958.

3 In the University of Aberdeen :  
Prof. J. R. Mallard

FALLARD has been appointed to the newly  
r of medical physics in the University of  
will take up his duties on October 1. Dr.  
up in 1944 from Northampton Grammar  
iversity College, Nottingham, where he  
30. He stayed on at Nottingham as a  
ent and demonstrator, working on the  
erties of uranium and its alloys. After  
J., he went in 1951 to the Liverpool Radium  
1953, he took a post at the Hammersmith  
the Postgraduate Medical School. Rapid  
owed and, when the Department of Medical  
reated in the Postgraduate School in 1958,  
deputy director and was appointed reader  
ity of London. Then, in 1964, he moved  
iversity to St. Thomas's Hospital Medical  
up a new Department of Biophysics. Dr.  
-doctoral work has covered many topics in  
35. He has been particularly interested in  
pplications of radioactive isotopes, usually  
one collaboration with clinical colleagues;  
is on scanning are well known. In addition,  
ctively engaged on electron spin resonance  
, especially as applied to wet tissue speci-  
earch on scanning methods and on electron  
e will be continued, along with other work,  
rity of Aberdeen. The arrival there of  
and his associates seems sure to give that  
l aspects of medical physics in the North  
and which the creation of the chair was  
rovide.

the University of Zambia :  
Prof. C. T. Mortimer

MOBTINER has been appointed to the chair at the University of Zambia, on secondment from the University of Keele, for a three-year period from

January 1, 1966. In addition, a Special Commonwealth Award has also been made to him by the Ministry of Overseas Development. Educated at Askworth School, Yorkshire, he took a B.Sc. degree at the University of Manchester in 1950 and the M.Sc. and Ph.D. degrees in 1951 and 1953, respectively. After two years at the University of Kharrourm, Dr. Mortimer took an appointment at the University of Keele in 1955, where he is now a senior lecturer. A Commonwealth travel grant enabled him to visit the University of Ibadan, Nigeria, for three months in 1960. Dr. Mortimer is the author of some forty papers and a monograph on thermochemistry, and a D.Sc. degree was recently conferred on him by the University of Manchester for this research. He has also published a number of papers on higher education in Africa.

Social Studies in the University of Newcastle upon Tyne : Prof. P. Collison

DR. P. COLLISON has been appointed to the chair of social studies in the University of Newcastle upon Tyne with effect from September 1. Dr. Collison was born in May 1925. After service in H.M. Forces he entered the University of Birmingham in 1947 and was awarded the degree of B.Com.(Hons.) in 1950. After a period of research he was awarded a Ph.D. degree in 1953 when he also became a research student at Nuffield College, Oxford. In 1954 he started to undertake part-time teaching in the Department of Social and Administrative Studies at Oxford, and since 1955 he has had a full-time post in that department. He is now university lecturer in sociology. His main research work has been in the field of urban studies, but he has had a subsidiary interest in institutions of higher education. He has published a large number of papers, and his book, *The Outer-School Walls: a Study in Social Class*, was published in 1963.

### Grants to Universities and Colleges

THE recommendations of the Estimates Committee in its fifth report for the session 1964-65 on grants to universities and colleges are discussed on p. 1319 of this issue of *Nature*. Nevertheless, the report contains such voluminous information on the functioning of the university grants system that a brief note on its contents seems desirable. Included with the report of the Estimates Committee itself and the minutes of evidence taken before its sub-committee are a number of memoranda. These include a memorandum submitted by the Department of Education and Science, which describes the system, including the constitution and the functioning of the University Grants Committee. Also presented are memoranda from the Committee of Vice-Chancellors and Principals describing its constitution and functions, and one from the Department of Scientific and Industrial Research on its Research Grants Committee, as well as on its policy in regard to computing science. Furthermore, there are memoranda from the Ministry of Health on its relations with the University Grants Committee, and from the National Health Service on the responsibility for the cost of building teaching hospitals. One submitted by the Royal Institute of British Architects deals with architects' fees for university buildings, and another, by Mr. W. E. Parker on university grants, considers the scope of the audit made of university accounts; the latter memorandum comments on the possibilities of using *post facto* examinations to make a comparative assessment of efficiency in regard to the expenditure of non-recurrent grants for buildings. A note by the Vice-Chancellor of the University of Birmingham deals with the control of expenditure and incentives to economy in university financial administration. A memorandum by the Department of Education and Science describes the *Trees* index used for measuring the change in university recurrent costs other than those on academic and related salaries.

Two particularly interesting tables from the University Grants Committee itself set out staff/student ratios on two different bases for each university, except Oxford and Cambridge, and university recurrent costs per student; while a note from the University of Kent instances losses of efficiency through inability to commit capital except at short range. It may be noted here that the Estimates Committee thought that it was time for the Vice-Chancellors' Committee to become more effectively representative, and that there was room for more intimate co-operation between the universities and the regional economic councils which have recently been set up. It also thought that the colleges of advanced technology might be unduly optimistic as to their prospects in the larger world of university finance, and was concerned that these colleges as a whole possessed no cushion against financial rigours such as the newly founded universities possessed in their large appeals. The Estimates Committee was critical of the lengthy process of negotiation between the Ministry of Health, the Department of Education and Science and the University Grants Committee involved in the development of medical schools and would welcome a simplification of the present procedure.

#### Production of Phosphorus and Its Compounds in Canada

The largest subsidiary overseas of the well-known Albright and Wilson Chemical Group of the United Kingdom is the Electric Reduction Company of Canada, Ltd., the main interest of which is in the manufacture of phosphorus, phosphoric acid, industrial and agricultural phosphates, and chlorates. 'ERCO', as it is known, operates in four factories: at Buckingham and Varennes, Quebec; at Port Maitland, Ontario; at Vancouver, British Columbia; and maintains its research laboratories and executive offices in Toronto, Ontario. A newly-issued and copiously illustrated brochure entitled *Ercos Today* vividly tells the growth story of this chemical manufacturing company and of its place as a supplier of these products to world markets (Pp. 48. Toronto: Electric Reduction Company of Canada, Ltd., 1965). The functions of each main plant and the processes involved are clearly described. At Varennes the primary concern is elemental phosphorus; the source is phosphate rock from Florida, whence it is shipped in 20,000-ton cargoes up the Atlantic seaboard and by way of the St. Lawrence Seaway to a wharf near the plant. Each shipload is unloaded and transported to the Varennes stock-piles within 30 h to cope with the daily capacity of two giant electric furnaces (more than 750 tons) to which are fed precisely sized and mixed quantities of coke, silica, and phosphate rock (tri-calcium phosphate) every 24 h. "Inside the steel-clad, carbon-walled furnaces, 35,000 kilowatts of Quebec's abundant hydro-electric power flow through huge carbon-based electrodes to convert these raw materials into more than 20,000 tons of yellow, wax-like elemental phosphorus each year." From Varennes phosphorus in water is transported to the Buckingham plant for further processing. Fundamental at Buckingham is the production of phosphoric acid; much of this is reacted with sodium carbonate or hydroxide to form eight different kinds of soda phosphate; some, with lime, goes to manufacture of mono-calcium phosphate, also, with appropriate chemicals, to organic phosphates; Buckingham also produces red amorphous phosphorus and phosphorus sesquioxide used in the match industry. Products of the Chlorate and Agricultural Chemicals Divisions are described; the role of the latest Port Maitland plant in manufacture of superphosphates and phosphatic fertilizers is particularly impressive.

#### World-wide Radio Noise Measurements

Since July 1967, measurements of the level of atmospheric noise received on eight radio frequencies between

0.013 and 20 Mc/s have been made at eighteen stations throughout the world in a co-operative programme coordinated by the U.S. National Bureau of Standards. The results of these measurements are published in a series of *Technical Notes* entitled *Quarterly Radio Noise Data*, the latest of which is No. 18-21 (Pp. vi+98. Washington, D.C.: Government Printing Office, 1965. 50 cents). This tabulates the results obtained during the three-month period December 1964-February 1965. These *Technical Notes* are prepared by W. Q. Crichtow, R. T. Disney and M. A. Jenkins of the Central Radio Propagation Laboratory, Boulder, Colorado. The present publication contains photographs of the standard type of atmospheric radio noise recorder and of the aerial system used at all the stations. An accompanying map shows the distribution of the 17 land stations, and a typical position of the floating Antarctic research vessel, U.S.N.S. *Ellanor*, which operates as a mobile station in the South Pacific. Following an introductory description of the evaluation of the three basic parameters of the noise—mean power, mean envelope voltage and mean logarithm of the envelope voltage—the values measured at every hour of each day during the three-month period are tabulated. A separate set of tables summarizes the observed values of radio noise for each of the frequencies and in 4-h time blocks throughout the three-month period, in accordance with the provisions of Report No. 322 of the International Radio Consultative Committee (CCIR). The values presented in the tables reflect the actual measured values of radio noise. The only editing for man-made noise or other contamination of the records has been done by the station operators, and no statistical study has been made in order not to delay the dissemination of the data in their present preliminary form. A short bibliography is attached to the report. This refers not only to individual scientific papers, but also to the publications of the CCIR and of the International Scientific Radio Union.

#### Advance In Knowledge of a Fossil Fern

Almost a century ago, Carruthers described a British Tertiary fern stem as *Osmundites douckeri*; he realized it was like *Osmunda* but he felt he knew too little to identify it with *Osmunda*. Recently, the stems of the Recent *Osmundaceae* have been investigated and we know how to distinguish the genera and even the sub-genera from a transverse section of the stem. Recently, also, a second British specimen was found, very carefully sectioned by the late W. N. Croft, and now described by Miss Marjorie E. J. Chandler (*Bulletin of the British Museum (Natural History)*. Geology. Vol. 10, No. 6: *The Generic Position of Osmundites douckeri Carruthers*. Pp. 139-161+12 plates. London: British Museum (Natural History), 1965. 42s.). She finds that it is a true *Osmunda* but belongs to the section *Plenasium* and not to the section which includes the British *O. regalis*. The ferns of *Plenasium* grow in South-east Asia. This then is another item in which our Eocene flora agreed with the living plants of Malaysia. It is interesting, too, that fragments of an *Osmundaceous* fern leaf from the British Tertiary (*O. lignitum*) also probably belongs to the sub-genus *Plenasium*—perhaps the two kinds of fossil represent a single species.

#### Soil Moisture

ALTHOUGH an estimate of moisture content is one of the most common exercises in soil analysis, it is realized that the methods used have various disadvantages. A useful review, with a comprehensive bibliography, on "Measuring Soil Moisture", by F. Cope and E. S. Trickett, appears in *Soils and Fertilizers* (28, No. 3, 201; 1965). As in other analytical techniques, the sampling error imposes limits on the reliability and reproducibility of the results, and the need for a quick and accurate method for measuring soil moisture *in situ* is emphasized. The authors deal with the estimation of the amount of soil moisture by

netric, lysimetric, penetration, chemical, methods. The most successful nuclear probe containing a source of fast neutrons, slowed down by the hydrogen of the soil, is a slow neutron detector. The energy of neutrons may be measured by tensimetric-pressure, resistive, thermal and electrical methods. The neutron probe is cheap and can give values over a wide range, but its accuracy is not very precise. Other methods await investigation or improvement, and some system of recording is required to reduce the labour needed because of soil variability.

#### In Tasmania

Archaeological research in Tasmania has been initiated, and one of the first reports appears in *Man* ("Excavations on a Stone in Tasmania", by Rhys Jones; 65, No. 62, 65). This is a short interim report of an excavation of the Bay of Fires on the north-east coast of which resulted in the excavation of a shell two stratified stone alignments. The stone alignments of Australia have for long been known to be excavations demonstrated that at least some arrangements must be of aboriginal origin. With certain stone settings of the Australian is possible that the Bay of Fires alignments are ceremonial centres, and the nature of the site is the first time that the tradition of such stone alignments in Tasmania must have existed for an unknown length of time.

#### The Shipwreck

The wreck off the island of Antikythera, first discovered in 1900, is well known not only because it was the earliest wreck found but also because of the wide range of objects recovered, including the papyrus. Some controversy has developed over the date of the wreck, and, using a recent use of the computer as a basis, a team of specialists has examined in detail the glass vessels, the Greek Roman pottery and amphorae, in an attempt to determine precisely the date of the disaster (*The Shipwreck Reconsidered*. By G. D. Weintraub, G. R. Edwards, H. S. Robinson, Morton and E. K. Ralph. Pp. 48. *Trans. Soc.*, New Series, 55, Part 3, 1965). All the evidence suggests a time between 80 and 50 B.C., a fragment of wood from the ship yielded a date of  $220 \pm 43$  B.C. (T-846, half-life of  $^{14}\text{C}$  represents the time of the cutting of the plank). The main cargo of the vessel, sculpture, have been on its way to Rome as spoils from the Mediterranean shores, although its exact place is unknown. Fragments of the actual ship were discovered in 1900, and P. Throckmorton contributes a statement of their value towards a reconstruction of the ship. This has been augmented by the 1953 examination of the wreck by men from the island which suggests that a substantial part of the ship still await recovery from the great depth of the sea.

#### Human Affairs

Years ago biology was little studied in the British Isles. In the junior schools the teaching consisted almost entirely of nature study or botany; in secondary schools little but botany and that largely in girls' schools. In 1935 the *British Biology* was founded by the then British Biological Council with the general aim of developing biology in schools. The particular aim was to encourage growth up with a better understanding of nature and working of their own bodies and

acquire a greater sense of responsibility for their conduct in personal and social life. With the spread of biology teaching, the Council broadened its aims to focus greater attention on human biology and, in 1942, the name of the journal was changed to *Biology and Human Affairs*. From the beginning it has appeared once a term and, largely through voluntary effort, has maintained a high standard of contributions which have done much to bring about greater awareness of social biology among those who teach biology in schools and colleges. For nearly the whole of its existence the editor of the journal has been R. Weatherall, late of Eton College, who must be congratulated on maintaining such a high standard in a wide range of contributions over so many years. Further information about the journal can be obtained from the Editor, British Social Biology Council, 69 Eccleston Square, London, S.W.1.

#### Experiments on Living Animals

The Universities Federation for Animal Welfare (UFAW), 7a Lamb's Conduit Passage, London, W.C.1, has issued the following statement: "The Home Office report on the above subject for the past year, which was published on August 17, shows that of the 4.5 million animals affected, 4 million were used for the testing of drugs, for experimental inoculations, and for like purposes. A large proportion of such procedures are concerned with toxicity-testing, which has greatly increased since the thalidomide tragedy was so dramatized as to give rise to a panic. In our view, which seems to be shared by most scientists who have a knowledge of the subject, many of the tests are necessitated by what may be called 'political' rather than scientific considerations and are, in fact, valueless, entailing a wasteful use of animals; moreover, in other cases it may well become possible to improve the technique from a humane point of view. UFAW is accordingly about to set on foot, under the guidance of its expert Scientific Advisory Committee, a three-year investigation of toxicity-testing, centred in the Medical School in the University of Birmingham and directed by one of the most eminent authorities on the subject. This undertaking will cost at least £30,000, but while its primary object is to save animals from useless suffering it is almost certain to lead also to results beneficial to human medicine, if the requisite financial support can be obtained".

#### Field Equipment for Naturalists

Much useful advice for naturalists contemplating the purchase of binoculars, telescopes, tape-recorders, tents, clothing, transport, compasses, thermometers, barometers, light meters, maps or cameras is contained in a special supplement of *Animals* (6, No. 14). The issue also contains articles on "Marine Life of North America's Pacific Coast", by Prof. C. M. Yonge; "Bird Watching in Jamaica", by M. S. Curtler; "Pets", by Dr. Maurice Burton; "The Ngorongoro Crater", and "Lake Manyara National Park"; and "Britain's Bats", by S. L. Bissacrot.

#### Lincolnshire Naturalists

In his presidential address to the Lincolnshire Naturalists' Union, Frank Norris reviewed present knowledge about the snakes of Lincolnshire, and appealed for an extension of the reporting system, with emphasis on observations of behaviour (*Transactions of the Lincolnshire Naturalists' Union*, 16, No. 1; December 1964). Besides the usual sectional reports, the *Transactions* also contain articles on the "Basal Lias near Long Bennington", by Dr. P. E. Kent; "Lincolnshire Natural History Recording Units", by Mark R. D. Seaward; and "Biological Surveys of the Humber Estuary", by E. Hinton Clifton.

#### The Beilby Medal and Prize, 1966

Awards from the Sir George Beilby Memorial Fund are made by the Administrators of the Fund, representing

the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals. Sir George Beilby was president of each of these three bodies, and they jointly sponsored the appeal for subscriptions whereby the Fund was raised as a memorial to him after his death in 1925. The Beilby Medal and Prize, which consists of a gold medal and a substantial sum of money, is specified as being "For Advancement in Science and Practice". Such an award is now being offered annually. The awards are made to British scientists in recognition of independent original work of exceptional merit, carried out continuously over a period of years and involving the development and application of scientific principles in any field related to the special interests of Sir George Beilby, namely chemical engineering, fuel technology or metallurgy, in their modern interpretations. The awards are intended as an encouragement to younger men and women (preferably under the age of 40) who have done distinguished work of practical significance in any of these fields. The award for 1966 is shortly to come up for consideration. Outstanding work of the nature indicated may be brought to the notice of the Administrators, either by persons who desire to recommend the candidate or by the candidate himself, not later than December 31, 1965, by letter addressed to the Convener of the Administrators, Sir George Beilby Memorial Fund, the Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

#### Meldola Medal, 1965

THE next award of the Meldola Medal, the gift of the Society of Macrobasians, will be made early in 1966 to the chemist who, being a British subject and less than 30 years of age on December 31, 1965, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31, 1965. Further information can be obtained from the President, the Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, the envelope being marked "Meldola Medal".

#### Announcements

DR. M. C. WILLIAMS has been appointed to the directorship of the Virus Research Institute at Entebbe, and has already taken over his duties.

THE 1965 congress of the International Federation for Documentation will be held in Washington during October 10-16. Further information can be obtained from the

Secretariat of the Congress, 9650 Wisconsin Avenue, Washington, D.C.

A SYMPOSIUM on "Computers in Medicine" will be held in Queen's University, Kingston, Ontario, during October 7-8. Further information can be obtained from the Director of Continuing Education, Faculty of Medicine, Queen's University, Kingston, Ontario.

THE national conference of the Institute of Personnel Management on "Making the Most of Manpower" will be held at Harrogate during October 7-9. Further information can be obtained from the Institute of Personnel Management, 80 Fetter Lane, London, E.C.4.

A MEETING on "Oxidation of Metals", organized by the Société d'Etudes, de Recherches et d'Applications pour l'Industrie, will be held in Brussels during October 6-8. Further information can be obtained from Mr. C. Sonnen, o/o S.E.R.A.L., 1091 Chaussée d'Alsemberg, Brussels 18.

A SYMPOSIUM on "Industrial Organic Analysis" sponsored by the Analytical Chemistry Division of the Chemical Institute of Canada, will be held at Sarnia during October 4-6. Further information can be obtained from R. M. Small, Research Department, Polymer Corporation, Ltd., Sarnia, Ontario.

AN informal meeting of the Physical Biochemistry Group of the British Biophysical Society on "Light Scattering" will be held at the School of Pharmacy, University of London, on October 4. Further information can be obtained from Prof. L. Saunders, School of Pharmacy, Brunswick Square, London, W.C.1.

A CONFERENCE on "Mathematics for Engineers", sponsored jointly by the Engineering Institutions Joint Council, the Institute of Mathematics and its Applications and the Joint Mathematical Council of the United Kingdom, will be held at Queen Mary College, London, during September 30-October 1. Further information can be obtained from the Registrar, Institute of Mathematics and its Applications, o/o Imperial College of Science and Technology, London, S.W.7.

CORRECTION. Prof. A. H. Glasser has written to the Editor stating that the chemical compound described in his joint communication with Dr. C. Beretta and Dr. R. Ferrini, which appeared on p. 421 of the July 24, 1965, issue of *Nature*, was in fact "1,6-Dimethyl-8 $\beta$ -carbobenzylxyaminomethyl-10 $\alpha$ -ergoline" and not "1-Methyl-8 $\beta$ -carbobenzylxyaminomethyl-10 $\alpha$ -ergoline".

## THE NIGHT SKY IN OCTOBER

All times are in Universal Time

MOON		CONJUNCTIONS WITH THE MOON	
New Moon	24d 14h	Venus	28d 00h, 2° S.
Full Moon	10d 14h	Mars	28d 02h, 0.01° N.
		Jupiter	16d 04h, 3° S.
		Saturn	7d 16h, 3° N.

#### PLANETS

Times of Rising (R) and Setting (S) during the month							
Name	R/S	Beginning	Middle	End	Mag.	D <sub>g</sub> (10 <sup>6</sup> miles)	Zodiacal position
Mercury	—	Unfavourably placed for observation			—	120	—
Venus	S	18h 45m	18h 26m	18h 25m	-3.8	84	—
Mars	S	19h 10m	18h 45m	18h 30m	+1.4	180	Scorpio
Jupiter	R	21h 00m	20h 05m	19h 05m	-2.1	484	Gemini
Saturn	S	2h 30m	2h 25m	1h 30m	+0.9	836	Aquarius

D<sub>g</sub> is the distance of planet from the Earth on the 15th of the month

#### OCCULTATIONS OF STARS BRIGHTER THAN MAGNITUDE +6 AT GREENWICH

Star	R/D	Time	Mag.
27 Cap	D	5d 21h 58.4m	+5.6

(D, disappearance; R, reappearance)

#### MEMOIRS

Name	Active period	Date of maximum	Radiant	Remarks
Glaucobids	9d-10d	9d 18h	262° R.A. + 54° Dec.	Unfavourable as minor activity expected
Orionids	15d-25d	21d	96° R.A. + 15° Dec.	Fairly favourable

#### OTHER PHENOMENA

16d 12 h, Mars 4° N. of Antares.  
17d 15h, Venus 2° N. of Antares.  
19d 15h, Venus 1.6° S. of Mars.  
28d 02h, Mars occulted by Moon (visible Australasia and Pacific only).  
Taurid meteors became active after 28d.

## THE ELECTRICAL RESEARCH ASSOCIATION

fourth annual general meeting of the Research Association held on April 28 annual report for 1964\*.

rd, Sir Ronald German, president of the fers to the work of the Association having d, in the main, in relation to the electricity y, but in recent years increasing attention oted to light current problems and this most certainly be accentuated.

rrations on the year's work are made in a tory section constituting the report of the s is followed by the Director's report on ich summarizes the activities of the six ons and the Electronics Department. A s devoted to membership, public relations, reau and library. A full list is given of the ts issued during the year. The remainder mprises a list of members of the Association, members of the Council and committees. es are listed under the particular division is attached, and of particular value is the statement of the terms of reference of

of Government grant to the Association, the Department of Scientific and Industrial e to an end in December 1964, and during w application had been prepared and sub- result of this application had been the r cent grant for a three-year period, subject ion collecting at least £350,000 of grant- e.

the income of the Electrical Research s increased by 90 per cent, or, more realistic- of 1955 spending power, by 52 per cent, e annual total of some £352,000. It is, ularly noteworthy that during this period a of total income derived from sponsored supported researches has increased from ent.

of the year, the Association transferred to of Reading the Field Station at Shinfield, past twenty years work has been carried on e applications of electricity in agriculture ure. It was felt that there would be co-ordinating more closely the work at the ion with that of the Faculty of Agriculture sity and to that end a joint agreement was - the University, the Electricity Council rical Research Association.

association moved its headquarters and main o Leatherhead in 1956, the facilities for ting remained for the time being at Perivale. 64 a new switchgear laboratory was built at Leatherhead and the work transferred. ening of this new laboratory was in October

sion dealing with insulating materials, results a two programmes of fundamental investiga- tion to the stable state, work on the dielectric rogen bonding has been completed and a ed dealing with possible implications for uctures. An important fact has emerged e mechanism of degradation of ceramics ric field at high temperatures, namely, that chemical rather than purely electrical in is very dependent on the materials of the d on the ambient atmosphere. Further

investigations have been made on the trapping of surface charges in dielectrics and an apparatus has been constructed which enables charges to be deposited, either directly electrically or as a result of photo-electric emission. Theoretical work on dielectric properties has led to a generalization of the Onsager theory to the frequency-dependent case, and it has been shown that electrostatic dipole coupling plays an important part in determining the distribution of relaxation times. Research on fundamental phenomena of instability has included the development of a theory of ionic diffusion in impregnated paper capacitors and this has been found to be in satisfactory agreement with observation. Another theoretical study deals with the propagation of breakdown channels through liquids and regards the channel as a vapour bubble at high pressure. The subject of the intrinsic electric strength of plastics is being re-examined using an improved technique of measurement. By the new method, intrinsic electric strengths of about twice the value given by the old method have been obtained at a temperature of 85° C.

In the Power Plant Division work on steels for high temperature and on the properties of steam continues. The investigation of the magnetically constricted low-pressure d.c. arc has been completed. This study has provided useful information on the effects of boundary layers at electrodes immersed in a low-pressure laminar stream of plasma.

A special Research Advisory Committee and Technical Panel is directing the work on the synthetic testing of circuit breakers which comes within the Division of Switchgear, Transformers and Power System Behaviour. This represents a major co-operative undertaking in which manufacturers, the Central Electricity Generating Board and the Association are involved. It is hoped that the work will lead to the national adoption of a standard method of synthetic circuit-breaker testing. Work in progress to establish the validity of the method as applied to air-blast circuit breakers has compared the severity of the direct and the synthetic test in several hundred trials made at three of the major stations of the Association of Short-circuit Testing Authorities. The maximum power-level of these tests has been 1,200 MVamp and the maximum current =0 k.amp.

Work continues at the British Iron and Steel Research Association Laboratories on improved alloys for transformer sheet. The demonstration of a relationship between resistivity and saturation has prompted a design study among manufacturers to determine whether any reduction in saturation could be accepted in return for reduced losses from increased resistivity.

In relation to switching over-voltages, useful information on the detail of surge generation and transfer has been obtained from the analysis of data from site tests on a 100-MV generator-transformer installation. Energizing a 132/33-kV transformer, to which a 33-kV earthing transformer was connected, demonstrated magnification of the switching surges transferred to the earthing transformer resulting from resonances between the 132-kV and the 33-kV systems. An investigation in progress on tolerable levels of discharge severity for oil-impregnated, paper-insulated bushings has demonstrated that degradation can be caused by test over-voltages and by surges such as may occur in service.

In the field of power system analysis, the increased facilities of the network analyser or, as it is termed, "the Integrated Computer" have been used to study transient problems of greater complexity. In addition, feasibility studies have been made of the desirability of coupling a small digital computer to the transient analyser and of

1 Research Association. Forty-fourth Annual Report for December 31, 1964. Pp. 96. (Leatherhead: The Electrical Association, 1965.)

the potentialities of such a hybrid system in power system applications.

Experimental work on the current-carrying capacity of cables continues in relation both to steady-state and to fault conditions, and considerable information has been obtained from the co-operative field investigation on the influences of the thermal properties of soil. In relation to the calculation of cable ratings, methods are being developed for the utilization of digital computer programmes.

The behaviour of the British electricity supply system in relation to thunderstorm activity throughout the ten-year period 1950-60 is the subject of a comprehensive report. The report examines the frequency of supply interruptions in the high-voltage system, their relationship with thunderstorm activity, the effect of arc suppression coils, the rate of equipment failure and the protective effects of surge diverters and spark gaps on the rate of transformer failures. Reports have also been issued analysing the frequency and distribution of thunderstorms in Britain for the years 1962 and 1963, and a ten-year thunderstorm map of Britain for the period 1955-64 is in preparation. The collection of statistical information on the frequency of lightning discharges in different parts of the world is being facilitated by the adoption, as an interim international standard, of a modification of a form of lightning-flash counter originally developed in association with the Electrical Research Association.

Electric heating is represented, in the main, by a group of researches relating to off-peak floor heating, to ceiling heating and to thermal storage. The storage of off-peak energy by means of the lime-water reaction has been studied on a full-scale test equipment in the laboratory and, following a comprehensive theoretical assessment, experiments have been put in hand on the use of sodium hydroxide.

Within the division dealing with industrial applications, the programme of work on electrical equipment for hazardous atmospheres continues. In the same division research on methods of reducing contact erosion is being pursued by a detailed study of a novel dissimilar metal system.

It appears, from theoretical considerations, that metal transfer could be virtually eliminated for a certain range of circuit conditions by the use of suitably chosen dissimilar contact metals. This has been confirmed in a series of experiments using platinum as the positive and silver or palladium as the negative electrode. Experimental work on unbalanced magnetic pull in electrical machines is now in progress on a machine specially constructed and instrumented for these measurements.

The major part of the programme of the Electronics Department is on thin films and is supported by a group of industrial contributors and by the Ministry of Aviation. It is reported that work on the deposition of metal from an ion beam has encountered difficulties, due to a flow of neutral gas molecules from the ionization chamber through the extractor electrode. The Penning ion source has been replaced by one utilizing electron bombardment to ionize copper vapour. Experimental capacitors have been made by depositing silicon oxide dielectric films on gold electrodes. Early results, however, suggest that the silicon oxide films deposited under ultra-high vacuum conditions may be insufficiently oxidized. Work on the conduction mechanism in thin films has led to an investigation of the influence of the substrate material. It has been shown that the electrical conductivity of glasses used as substrates for microcircuits is high enough to contribute to the transport of electric charges by a thin film deposited on the surface. Two new lines of investigation have been started, one on the properties of semi-conductor materials in thin film form and the other on the resistance changes occurring in thin gold films when subjected to mechanical strain.

Some of the fundamental theoretical work which has been done in applying the theory of the electrical discharge to certain astrophysical phenomena has undergone further comparison with observation. During the past year it has been demonstrated that the maximum magnetic fields recorded by Babcock's solar magnetograph of the order of 1,000 gauss are compatible with the much larger fields of  $10^4$ - $10^5$  gauss deduced from the theory of solar flares some years ago.

J. GRING

## POWER SUPPLY IN BRITAIN

IN asking the House of Commons on August 4 to note the Report and Accounts of the Electricity Council for 1963-64 and of the Central Electricity Generating Board for 1963-64, Mr. F. Leo, the Minister of Power, said that the average cost of new conventional power stations had fallen from about £80 per kW in 1955 to about £40 to-day. Britain had by far the largest output from commercial nuclear power stations of any country, and was producing more nuclear power than the whole of the rest of the Western world, including the United States. Whatever the outcome of the Government's present review of the second nuclear power programme, the industry would continue to need coal for many years to come, and the Generating Board was now using 64 million tons of coal, compared with 61 million tons in 1963-64. Fifteen new coal-fired stations were under construction, partly to replace the older stations which were closing down, and on completion of these stations the Generating Board would have much of its capacity in the form of new coal-fired stations. The working life of the new stations would be twenty-five years or more, and they would burn coal with high efficiency in the 500-MW sets which had been adopted as standard for the next few years. Forty-seven of these sets were now on order and they would produce substantially more power than the entire capacity of the industry ten years ago.

On the transmission side, the industry was introducing transmission at 400 kV. Great efforts were being made at

considerable cost to reduce the impact of the new lines on the countryside and this research had high priority. Some research was being undertaken into the use of d.c. transmission instead of a.c., and about one-third of the total expenditure of the Board on transmission lines in 1964 was spent on underground cables. This was expected to rise to more than two-thirds by 1970, and during the three years, commencing in 1968, the Board expected to spend £39 million on 1,350 miles of overhead lines, and £107 million on 500 miles of underground cable. Rural electrification was now approaching completion, and 94 per cent of the 280,000 farms in England and Wales had an electricity supply. In distribution, as in generation and transmission, research was going ahead and a new laboratory had been set up at Copenhurst. The major effort at the new laboratory would be concentrated on research into distribution and on appliances and methods of using electricity as part of a research programme covering generation, transmission and distribution, on which the industry planned to spend £10 million this year.

The Minister's observations on research were generally welcomed in the debate, but Mr. A. F. Palmer suggested that there might have been some neglect of research into the use of direct current. Sir Richard Nugent pointed out that the Select Committee on the Nationalized Industries had been critical of expenditure on research on transmission, and especially on distribution, particularly

boards. Mr. J. H. Osborn suggested that the Central Electricity Generating Board, and Energy Authority might survey the variety of water reactors, and asked whether the virtues of water and similar types of reactor for smaller units were being considered. The achievement of the Atomic Energy Authority in developing the gas-cooled reactor was welcomed in the debate. Mr. E. Lubbock and Mr. P. Jenkin were also present. The comparative cost of the gas-cooled reactor developed in the United States at

Oyster Creek: this, it was said, could produce electricity at 0.84d. per unit. These and other speakers in the debate repeatedly stressed the importance of research. In replying on the debate, Mr. J. Morris, the Parliamentary Secretary to the Ministry of Power, said that the Minister was satisfied with the programmes to date and referred to the greater co-operation and co-ordination recently established between the gas, electricity and coal industries. As regards Oyster Creek, he said that this was not a comparison of like with like, and the Dungeness tenders were all competitive under British conditions.

## BRITISH RESEARCH AND DEVELOPMENT IN TECHNOLOGY

In an answer in the House of Commons on July 27, 1965, the Minister of Technology, said that the Research Development Corporation was making grants in support of programmes and projects of research and development by various firms in the country. His Department would continue to support research by sharing the cost of contracts under the Computer Techniques Programme, involving commitments by the Government of about £965-66 and through contracts with universities and industry to a further £500,000. It had been made with the Minister of Housing and Government to bring the Computer Advisory Committee to the notice of local authorities. Twenty-three American computers were on order for Government departments, including the General Post Office. Computers of American design and foreign origin were in use in Government departments, nationalized industries. Eighty computers in Britain were in use in Government departments and 66 in the nationalized industries. A programme between the Atomic Energy Research Establishment and industry on the desalination of sea-water was under study for a 30-Mgal./day plant, distillation techniques, had been completed in 1964 with Weir, Westgarth, Ltd.

He said that he had appointed Dr. J. B. Condon to the Ministry of Technology with effect from July 12, and that Dr. Adam would be in charge of the scientific and technological work of the industry. An chart for the Ministry of Technology was the Official Report for July 27, and the work of the Economics and Statistics Division in detail. This Division is organized in four branches: Economics Branch, responsible for advising on economic aspects of the Ministry's policies and

This Branch provides support for the industries conducted by the technological units within the Ministry. (2) Statistics Branch is responsible for collating, analysing and statistics of industries for which the Ministry has functions. These statistics are collected by the Board of Trade. (3) Manpower

Branch, which is concerned with manpower resources for science and technology and keeps under review the human and social problems resulting from technological change. (4) Engineering Branch, which has the main function of initiating or encouraging action to enhance the status of engineers and to improve the supply. It is also responsible for co-ordinating the implementation of the recommendations of the Fielden Report on Engineering Design.

Mr. Cousins also stated that the Ministry communicated technological information by personal contact, scientific and technical publications, exhibitions, conferences, press, film, radio and television, and was building up a network of regional offices and industrial liaison centres to supplement this effort. The Ministry's laboratories dealt with about 2,500 enquiries each month, mainly from industry. Much information was being received from scientific counsellors in foreign countries. The Department was undertaking a technical and economic study of the scientific industrial process-control instrument industry, and had initiated studies of engineering standards, the metric system and the industrial use of new materials. Also contained in the Official Report for July 27 was a full list of the leaders of the various scientific and technological teams studying selected industries and processes, with their date of appointment and relevant experience.

On July 27, replying to a question regarding the Advisory Council on Technology in the House of Lords, Lord Snow, the Parliamentary Secretary to the Ministry, said that the Council had met ten times; its terms of reference were to advise on the application of advanced technology in British industry and to give special attention to the industries for which the Minister had sponsorship responsibility. Among subjects considered have been the status of engineers and designers, development of British standards for export markets, the promotion of the metric system and problems of industrial structure. The relations between the Council for Scientific Policy and the Advisory Council on Technology were close and there was common membership. Lord Snow thought that there was no danger of any serious lacuna between them. Relations between the Ministry and the Department of Economic Affairs must also be close and he thought there was little danger of overlapping.

## THE MELLON INSTITUTE

The second annual report of the Mellon Institute \* for the year ended February 28, 1965, at the close of which the staff of 539 included 355 professional and technical personnel. A list of visitors' lectures at colloquia and another of members' publications during the year, and brief accounts of research investigations

during the year refer, under biochemistry and molecular biology, to improvements in instrument design and experimental procedures which have given a precision of 0.2-0.3 per cent in determining sedimentation coefficients in examining structural transformations in *Bromegrass* mosaic virus, while further electron microscopical studies of actomyosin have confirmed the identification of 'ladders' as the principal morphological form of con-

\* Fifty-second Annual Report for the Fiscal Year ended February 28, 1965. (Pittsburgh: Mellon Institute, 1965.)

tractile suspensions. Visible light shadows of a model of part of the tropocollagen macromolecule, made from foam plastic atomic models, with one or more of the three strands broken indicate that electron microscopy should detect collagenase activity on tropocollagen.

Environmental investigations have been concerned with the purification of the atmosphere, the electrokinetic properties of particles suspended in water and the presence of organic compounds in water. A revision of Volume 2 of *Systems and Specifications of the Steel Structures Painting Manual* was prepared, and the feasibility of protecting steel temporarily by depositing small amounts of metallic zinc on bare metal surfaces by shot-blasting was examined. An investigation of the damaging effects of light on art objects and of new methods for technical examination of museum objects continued; several reviews of the literature were published.

Under "Structure and Properties of Organic Materials" reference is made to a kinetic study of the nucleocarbamoylpyridinium ion and to the ring-opening reaction of dimethylcarbamoylpyridinium chloride with hydroxide ion to give a compound which afterwards decomposes to glutacondialdehyde; to the synthesis of the tetracyano-dimethane derivative of dibenzopentalenoquinone, which forms deeply coloured salts with amines; to the synthesis of turnefordene and hastanecine and their identification with the basic nitrogenous fragments obtained by cleavage of *Sesecio* alkaloids; and to the identification of hydrocarbons obtained by heating 1 : 2 : 6-cyclononatriene. Further work on the thermal degradation of wet marine muds has demonstrated the formation of benzene, thiophen, styrene and possibly methylthiophen, in addition to the toluene and *m*-xylene known to arise from the carotenoid components. Since phenylalanine yields benzene, toluene, styrene and other products, it may be a natural precursor of these aromatic hydrocarbons. Investigations of petroleum asphaltene in the bending region of the infra-red have indicated the existence of four distinct absorption bands, and an extension of the dry-filtration theory has provided a reliable means for specifying requirements of filter media based on the electrostatic contributions of both the fabric and the collected particulate matter.

Considerable information was obtained during the year on internal motions in radicals by examining details of their electron spin resonance patterns, while the Bendix Time-of-Flight mass spectrometer has proved very suitable for examining ionization reactions occurring with electrons of less than several thousand electron volts energy. A series of cyclo dienes and their diepoxides has been synthesized for cyclopolymerization investigations of dicyclic compounds; light-scattering and viscosity examinations of a series of linear polystyrenes of narrow molecular weight distribution between 10° and 110° C in dilute solutions in decalin were almost completed. Light scattering and viscosity investigations of some poly(*bis*-phenol-*A*-carbonate) fractions were undertaken, and a comparison was made of the crystallization kinetics of nylon 6 and nylon 66 in the light of recently developed concepts of crystallization. Search continued for improved weather- and corrosion-resistant coatings for building materials.

The viscoelastic behaviour of glass-forming materials is being examined and further mathematical analyses made on the theory of the free-vibration experiment for a linear viscoelastic material. The crystal structure of tetrahydro-*p*-benzoquinone dehydrate has been determined and refined from three-dimensional Weissenberg data and an electron spectrometer further developed and used to investigate inelastic electron scattering. Experimental facilities for low-frequency internal rotation spectroscopy were greatly expanded, and work on internal rotation continued vigorously, while the procedure for obtaining accurate solutions of the molecular Schrödinger equation was improved. The measurement and interpretation of the electronic spectra of transition metal cyanide complexes were extended to all the known complex cyanides, and the presence of hydrophobic bonding in the quaternary ammonium halides in aqueous solution was investigated by electrical conductance, transference and viscosity measurements. Chemical and physical properties of a set of molten quaternary ammonium salts were investigated, as well as the electrical conductivity of acidic solids in ultra-high vacuum and the silica-alumina catalysed isomerization of cyclopropane and the heat capacity below liquid-helium temperature of a series of copper-zinc alloys.

## MAGNETOSPHERE AND THE MARTIAN BLUE CLEARING

By DR. RONALD BLUM

Department of Physics and the College, University of Chicago

WHEN Mars is observed in yellow or red light, surface details of the planet can be seen; however, in blue or ultra-violet light of wave-length  $\lambda < 4550 \text{ \AA}$  one sees a uniformly hazy disk with occasional bright patches, which obscures surface details<sup>1</sup>. This blue haze, believed to be due to a 'violet layer' in the upper Martian atmosphere, has been observed to clear up for several days at a time, particularly near opposition, when the Earth is between Mars and the Sun. It has been suggested<sup>2</sup> that the blue haze may be due to the ionizing effect of solar protons on the Martian atmosphere; the protons are deflected by the Earth's magnetic field when the two planets are in opposition. This hypothesis has been rejected by Sagan<sup>3</sup> on the grounds that: (1) 2-MeV protons are required to produce molecular ions with the requisite absorption bands at an altitude of 150 km in the Martian atmosphere, whereas solar wind protons are of the order of 1 keV; (2) proton fluxes of  $5 \times 10^{14}/\text{cm}^2\text{-sec}$  are needed—large compared to solar wind fluxes of the order of  $10^8/\text{cm}^2\text{-sec}$ ; (3) the magnetosphere is too small to produce the required shadow effect at Mars; (4) the dipole field falls off too rapidly to have any effect at Mars's radius.

A possible answer to objections (3) and (4) may be found in Michel's calculation of the Mach angle of the oblique hydromagnetic shock extending into the solar wind downstream of the magnetosphere<sup>4</sup>. Typical values of the solar wind parameters yield a hydromagnetic Mach number of 6, and a Mach angle of  $8.5^\circ$ – $9.5^\circ$  (the Mach cone is slightly asymmetrical). Thus, the region behind the shock, or 'wake', would have the appearance of a circular cone with its apex at the Earth, and an apex angle of approximately  $9^\circ$ . The axis of the cone should actually lag the Earth-Sun line by about  $5^\circ$  due to the orbital motion of the Earth. This is very suggestive when compared with the observation<sup>5</sup> that the Martian blue clearing is not observed whenever Mars lies very far above or below the ecliptic at opposition. Thus it would seem that clearing is possible only when Mars passes through a cone of small angle the apex of which is at the Earth, and the axis of which is approximately along the Earth-Sun line.

If we assume that the Earth and Mars both lie in the ecliptic plane and have nearly circular orbits, we may roughly calculate how long it would take Mars to pass through the conical wake of the Earth. We let  $R_e$  be the radius of the Earth's orbit;  $R_m$  = the radius of Mars's

orbit;  $T_e$  = the period of the Earth's orbit;  $T_m$  = the period of Mars's orbit;  $\alpha$  = the Mach angle of the Earth's wake;  $T$  = the time required for Mars to pass through the wake. Since the base of the wake at Mars's orbit has a radius:

$$R = (R_m - R_e)(\tan \alpha) \quad (1)$$

it subtends an angle of  $2R/R_m$  at the Sun. If Mars's trajectory subtends an angle  $2\pi T/T_m$  at the Sun during time  $T$ , then the Earth's trajectory subtends an angle:

$$2\pi T/T_e = 2\pi T/T_m + 2R/R_m \quad (2)$$

during this time. Thus we find:

$$T/T_e = \left( \frac{R_m - R_e}{R_m} \right) \left( \frac{T_m}{T_m - T_e} \right) \left( \frac{\tan \alpha}{\pi} \right) \quad (3)$$

which yields  $T = 10.5$  days for closest opposition (34.5 million miles) and  $T = 16.1$  days for furthest opposition (63.5 million miles), for  $\alpha = 9^\circ$ . Sagan<sup>8</sup> notes: 'Most reported durations of opposition blue clearings lie in the range between 1 and 30 days, although there is a tendency for blue clearings at favourable oppositions to last nearer 30 days than 1'. W. M. Sinton<sup>9</sup> estimates the average clearing to last about ten days. Thus, the interference of the Earth's Mach cone with the solar wind yields clearing times of the right order of magnitude. This wake should not be confused with the extended tail of the magnetosphere, a cylinder of approximately forty Earth radii in diameter and far too small to account for the observed clearing times.

We may adduce further observations to favour the hypothesis that the Martian blue clearing is caused, in some way, by the magnetohydrodynamic wake due to the interaction of the geomagnetic field with the solar wind. These are: (1) clearing may lead or lag opposition by as much as 10–14 days, an effect which shows some dependence on the heliocentric latitudes of the Earth and Mars; (2) clearing durations seem to depend inversely on the difference in heliocentric latitudes of the Earth and Mars; (3) there is a statistical tendency for blue clearings to lag opposition<sup>1</sup>. The first two observations are plausible if one considers the asymmetries and fluctuations in the solar wind; the last agrees with the lag due to the Earth's orbital motion. Furthermore, preliminary *Mariner IV* results<sup>6</sup> indicate that the surface pressure of the Martian atmosphere is only about ten millibars, that its magnetic field is not greater than 0.1 per cent that of the Earth, but that it does possess an ionosphere with a density of about  $10^6$  electrons/cm<sup>3</sup>. Thus, the violet layer is much more exposed to the solar wind than previously surmised.

If we now repeat Sagan's calculations, using Chamberlain's model<sup>7</sup> of the Martian atmosphere, reduced in density by an order of magnitude to agree with the *Mariner IV* results, we find that there are approximately  $10^{-4}$  g/cm<sup>3</sup> of gas above the violet layer. If we compare this figure with the range of protons in air<sup>10</sup> we find that  $> 85$ -keV protons can penetrate to this depth in the Martian atmosphere. Such energies are commonly found in solar flares; furthermore, since the notoriously turbulent interplanetary magnetic field should be even more unstable in the vicinity of Mars, there is an enhanced possibility of local acceleration processes. Objection (2) still holds, implying that some other mechanism besides that of Urey and Brewer gives rise to the blue haze; however, my hypothesis does not stipulate the mechanism of interaction, only that such an interaction may occur.

The question arises: Will the shock attenuate appreciably as it expands downstream of the Earth, and will the energy density in the shock be a significant fraction of the energy density of the solar wind arriving at the orbit of Mars? To answer these questions we must look at the shock from the point of view of an observer moving outward from the Sun with the solar wind. As the Earth approaches him the solar wind is forced to flow around the magnetosphere, which is approximately a cylinder with a hemispherical nose some twenty to forty  $r_e$ ,

Earth radii ( $r_e = 6,400$  km), in diameter. This will compress the interplanetary magnetic field around the obstacle and form a cylindrical magnetosonic wave propagating radially outward into the solar wind from the surface of the magnetosphere. This is, in essence, the stationary shock wave as seen by a terrestrial observer.

To calculate the energy in this wave we may estimate energy density by means of the normal one-dimensional magnetohydrodynamic Rankine-Hugoniot conditions applied at the front of the magnetosphere. For typical values of the solar wind's parameters its internal (magnetic plus thermal) energy density at Mars's orbit is  $U \sim 10^{-10}$  erg/cm<sup>3</sup>, its convective energy,  $W \sim 20 \times 10^{-10}$  erg/cm<sup>3</sup>. The internal energy density behind the shock at Earth is calculated<sup>11</sup> to be  $U_{se} \sim 100 \times 10^{-10}$  erg/cm<sup>3</sup>, initially located in an annular pulse of radius  $10r_e$  about the Earth-Sun axis. For a hydromagnetic Mach number  $M = 6$ , this annular pulse will undergo an increase in radius of  $(R_m - R_e)/M$  by the time it reaches the orbit of Mars. Since the conductivity of the solar wind is  $\sigma \sim 5 \times 10^{-7}$  (E.M.U.), the characteristic decay time of hydromagnetic disturbances is  $\tau \sim 4\pi\sigma L^2$ , where  $L \sim 10r_e/M \sim 10^6$  cm; hence,  $\tau \sim 6 \times 10^{13}$  sec. Thus, neglecting turbulence or dissipation we assume that the wave propagates undistorted through the interplanetary medium; the decrease in its energy density is solely due to geometrical factors. At Mars the energy density of the pulse is  $U_{sm} \sim (10Mr_e/(R_m - R_e))U_{se} = 0.5 \times 10^{-10}$  erg/cm<sup>3</sup>, or 50 per cent of  $U$  and 2.5 per cent of  $W$ . Despite the imprecision of such a calculation, these numbers lend credence to the idea that the shock wave may persist with sufficient strength to affect significantly the flow of the solar wind at the orbit of Mars, where the weakness or absence of a Martian magnetic field leaves the violet layer vulnerable to changes in the solar wind.

Although the shock does not attenuate, one would expect its energy density to be degraded in the form of a turbulent wake as it propagates outward; in such a case it has been suggested<sup>12</sup> that the passage of the shock may serve to trigger an instability in the wind capable of causing the blue clearing. Another possibility is that the tail of the Earth's magnetosphere is kept open, and even broadened, by the radiation pressure of hydromagnetic waves propagating into the tail from regions of higher magnetic field<sup>13</sup>. It should be mentioned that preliminary *Mariner IV* results from measurements made over a period of 5 days at  $3,000r_e$  downstream of the Earth showed no evidence of a geomagnetic tail; this does not, however, preclude the possibility of the shock, through which the spacecraft may have already passed.

In my calculations I have assumed the duration of the pulse to be determined by the radius of the magnetosphere, not by the length of the magnetospheric tail.

In conclusion, I should emphasize that this article was written in a speculative vein in the hope of stimulating further discussion of this topic. There is, at present, only one competing theory<sup>14</sup>, namely, that the blue haze is caused by dust particles from meteor streams passing Mars, and that the blue clearing is a purely random effect, unrelated to opposition.

I thank Drs. E. N. Parker, A. Palm and W. M. Sinton for their advice.

# MAGNETOTURBULENT ENERGY AND STABILITY OF SUPERMASSIVE STARS

By S. P. S. ANAND

California Institute of Technology, Pasadena, California

THE discovery and subsequent investigation of the quasi-stellar radio objects, or 'quasars', have aroused great interest by many investigators<sup>1-3</sup>. The observed luminosities are of the order of  $10^{44}$  ergs sec<sup>-1</sup> and their lifetimes fall in the range of  $10^4$ - $10^6$  years. Hoyle and Fowler<sup>4</sup> proposed that a mass of the order of  $10^6 M_\odot$  has condensed in the galactic nucleus into a single massive star in which nuclear energy generation occurs. Later on they suggested the release of gravitational energy during general relativistic collapse after the exhaustion of nuclear matter by the ONO bi-cycle. Fowler<sup>5</sup> showed that these massive stars become unstable before the central temperature has risen to  $5.8 \times 10^7$  °K for  $10^6 M_\odot$ . This discussion was based on the binding energy of massive stars in hydrostatic equilibrium which he derived from general relativistic equations in the post-Newtonian approximation of general relativity. Chandrasekhar<sup>6-11</sup> used the exact dynamical equations of general relativity and obtained the same result. Fowler showed that general relativistic instability sets in for masses greater than  $10^6 M_\odot$ .

Recently, Fowler<sup>12</sup> suggested that this general relativistic instability can be removed by a small amount of rotation. On assuming that these massive stars are uniformly rotating gaseous systems, he showed that masses up to  $10^7 M_\odot$  are possible, consistent with the maximum angular momentum. If one takes a non-uniformly rotating system in which the central regions rotate faster than the outer regions, then stable masses of  $10^6 M_\odot$ - $10^{10} M_\odot$  are also possible. In the case of uniform rotation, Roxburgh<sup>13</sup> also obtained the same result.

Layzer<sup>14</sup> suggested that magnetoturbulent energy can also be effective in stabilizing these massive stars. In this article, I shall show, using Fowler's binding energy method, that the turbulent kinetic energy associated with the internal magnetic disturbances (with conservation of magnetic flux) is also an effective physical mechanism to remove the general relativistic instability. It is found that stable masses of  $10^6 M_\odot$ - $10^{10} M_\odot$  are possible depending on the parameter  $\alpha$ , which will be defined later.

The binding energy  $E_b$  of a star is equal but opposite in sign to the total energy  $E$  due to rest mass energy and 'bulk motions' throughout the star and is given by:

$$-E_b = E = (M - M_0) c^2 + E_{\text{dyn}} \quad (1)$$

where  $E_{\text{dyn}}$  is the dynamical energy due to 'bulk motions'. Here:

$$M = \int_0^R dM_r = \int_0^R 4\pi r^2 \rho \, dr \quad (2)$$

where  $R$  is the radius of the star,  $M_r$  is the mass interior to radius  $r$ , and  $\rho$  is the mass-energy density measured by a local observer and is given by:

$$\rho = \rho_0 + \frac{u}{c^2} \quad (3)$$

where  $\rho_0$  is the rest mass density and  $u$  is the internal energy due to gas and radiation. The rest mass ( $M_0$ ) of the star is given by:

$$M_0 = \int_0^R \rho_0 \left(1 - \frac{2GM_r}{rc^2}\right)^{-1} dV \quad (4)$$

where  $dV$  is the co-ordinate element of volume  $V$ . Using equations (2)-(4) in equation (1), we get  $E$  in the post-Newtonian approximation as follows:

$$E = \int u dV - \int \frac{GM_r}{r} \rho \, dV + \int \frac{GM_r}{rc^2} u dV - \frac{3}{2} \int \frac{G^2 M_r^2}{r^2 c^2} \rho \, dV + E_{\text{dyn}} \quad (5)$$

The physical interpretation of each term is already given by Fowler<sup>5,12</sup>.

In the present case, the contribution of dynamical energy which arises due to magnetic disturbances is considered. It is well accepted now that, in a medium of high electrical conductivity, turbulence will be associated with a spontaneous generation and subsequent amplification of magnetic fields since the pioneer work by Batchelor<sup>15</sup>. Also, in a state of equilibrium, the energy per unit volume in the magnetic field and the velocity fields will approach equality or equipartition<sup>16,17</sup>. Later on Chandrasekhar<sup>18</sup> showed for stationary, homogeneous and isotropic turbulent conditions that magneto-turbulent energy ( $m_e$ ) is given by:

$$m_e = \frac{1}{8\pi} \langle H^2 \rangle = \alpha \frac{1}{2} \rho \langle v^2 \rangle \quad (6)$$

where  $\alpha$  is 1.6265,  $\langle v^2 \rangle$  and  $\langle H^2 \rangle$  are the mean square velocity and magnetic intensity respectively.

Assuming conservation of flux,  $\langle H \rangle R \sim \text{constant}$ <sup>14,18</sup>, since lines of force are frozen and they are crowded together. In this case we write  $E_{\text{dyn}}$  as:

$$E_{\text{dyn}} = \frac{m_e}{\alpha} = \frac{\Phi^2}{\alpha R^2} \quad (7)$$

where  $\Phi$  is the magnetic flux and all other constants are now included in  $\Phi^2$ .

The equation of hydrostatic equilibrium in the post-Newtonian approximation of general relativity is<sup>4</sup>:

$$\frac{dp}{dr} = - \frac{GM_r \rho}{r^2} \left(1 + \frac{p}{\rho c^2} + \frac{2GM_r}{rc^2} + \frac{4\pi p r^2}{M_r c^2}\right) \quad (8)$$

To obtain the virial theorem, we multiply equation (8) by  $4\pi r^2 dr$  and integrate, we get:

$$3 \int p dV - \int \rho \frac{GM_r}{r} dV + \int \frac{GM_r}{rc^2} p dV - 3 \int \frac{G^2 M_r^2}{r^2 c^2} \rho dV = 0 \quad (9)$$

Combining equations (5), (7) and (9), we get:

$$E = - \frac{(3\bar{\Gamma}_4 - 4)}{3(\bar{\Gamma}_4 - 1)} \int \frac{GM_r}{r} \rho dV + \frac{2}{3} \int \frac{GM_r}{rc^2} u dV + \frac{3}{2} \frac{5 - 3\bar{\Gamma}_4}{3(\bar{\Gamma}_4 - 1)} \int \frac{G^2 M_r^2}{r^2 c^2} \rho dV - \frac{1}{\alpha} \frac{\Phi^2}{R^2} \quad (10)$$

where we have put<sup>12</sup>:

$$p = (\Gamma_1 - 1) u, \quad \Gamma_1 - 1 = \frac{\gamma - 1}{3(\gamma - 1) - \beta(3\gamma - 4)} \quad (11)$$

where  $\beta$  is the ratio of gas pressure to total pressure due to gas and radiation. For massive stars  $\beta < 1$ , then:

$$\Gamma_1 \sim \frac{4}{3} + \frac{1}{\beta} \quad (12)$$

It should be noted that if we include Newtonian non-linear terms due to velocity (as Fowler<sup>12</sup> included centrifugal acceleration) in equation (8), then the coefficient of  $1/\alpha \Phi^2/R^2$  in equation (10) will become  $(5 - 3\Gamma_1)/3(\Gamma_1 - 1)$ , which, for massive stars, is of order one. I shall discuss this case more elaborately in a later publication, in which the interaction of magnetic fields with rotation will be considered. Using equation (2) in (10) and evaluating the integral for polytropic index  $n = 3$ , we get<sup>13,14</sup>:

$$\frac{E}{Mc^2} \sim -\frac{3}{8}\beta\left(\frac{R_g}{R}\right) + 1.265\left(\frac{R_g}{R}\right)^2 - \frac{1}{\alpha}\left(\frac{\Phi^2}{Mc^2 R^2}\right) \quad (13)$$

where  $R_g$  is Schwarzschild's radius and it is given by:

$$R_g = \frac{2GM}{c^2} = 3 \times 10^3 (M/M_\odot) \quad (14)$$

The condition of magnetic stability of a magnetic star due to Chandrasekhar and Fermi<sup>15,16</sup> is the following:

$$(3\Gamma_1 - 4)(|\Omega| - m_*) > 0, \Gamma_1 = \beta + \frac{(4 - 3\beta)^2(\gamma - 1)}{\beta + 12(\gamma - 1)(1 - \beta)} \quad (15)$$

where  $\Gamma_1$  is Chandrasekhar's radiative adiabatic coefficient. In general relativity  $\Gamma_1 \rightarrow 4/3$ , hence magnetic instability sets in if  $|\Omega| < m_*$ . This gives the critical value of  $\Phi_{cr}$  as:

$$\Phi_{cr}^2 = \frac{3}{2} GM^2 R \quad (16)$$

for polytropes  $n = 3$ . We define a parameter 'a' given by:

$$a = \frac{\Phi^2}{\Phi_{cr}^2} \quad (17)$$

which shows that magnetically stable configurations are possible only for  $a \leq 1$ . Using equations (16) and (17) in equation (13), we get:

$$\frac{E}{Mc^2} \sim -\frac{3}{8}\beta\left(\frac{R_g}{R}\right) + 1.265\left(\frac{R_g}{R}\right)^2 - \frac{3a}{4\alpha}\left(\frac{R_g}{R}\right) \quad (18)$$

Choosing the critical value of  $R_g$  at the moment when the minimum in  $E/Mc^2$  is reached, equation (18) gives:

$$R_{cr} = \frac{5.487}{a(1 + 0.8\beta/\alpha)} R_g \quad (19)$$

Now the radius of main-sequence massive objects given from the structure of the star in Schwarzschild radius unit is given by<sup>8</sup>:

$$R_{ms} = 7.5 \times 10^3 R_g \left(\frac{M}{M_\odot}\right)^{-1}$$

Hence from equations (19) and (20) we have:

$$\frac{R_{ms}}{R_{cr}} = 1.387 \times 10^3 a_1 \left(\frac{M_\odot}{M}\right)^{\frac{1}{2}}$$

where  $a_1 = (a + 0.81\beta)$ . Equation (21) shows that stability sets in for masses greater than:

$$M = 1.88 \times 10^{10} a_1^2 M_\odot$$

It can be seen from equation (22) that the magnetically stable masses (for  $a = 1$ ) up to the order of  $1.8 \times 10^{10}$  are possible (since  $\beta < 1$ ).

I have shown in this article that magnetoturbulent energy is also very effective in removing general relativistic instability. On varying  $a_1^2$  from  $10^{-1}$  to  $10^{-4}$ , we find that stable masses of  $10^9 M_\odot$ – $10^{10} M_\odot$  are possible. How the interaction between non-uniform rotation and magnetic fields reduces the angular velocity for equatorial instability, and their maintenance in supermassive stars will be discussed in much detail in a later publication.

I thank Prof. William A. Fowler for directing my interest to this problem, and for showing me the manuscript of his paper<sup>15</sup> in advance of sending it for publication. I also thank Dr. Gerard Stephenson, jun., for suggestions and comments.

## A NEW METHOD FOR DEUTERON STRIPPING CALCULATIONS (I)

By PROF. S. T. BUTLER

Dally Telegraph Theoretical Department, School of Physics, University of Sydney

AS is well known, all deuteron stripping reactions are potentially capable of yielding considerable information regarding nuclear energy-levels and nuclear structure. The simple theory developed many years ago by the present author<sup>1,2</sup> has proved useful for determining spins and parities of nuclear states in many cases. It suffers the disadvantage, however, that it over-estimates absolute cross-sections, so that it may reasonably be expected to yield information only of ratios of nuclear reduced widths. Moreover, experimental angular distributions of reactions involving medium and heavy nuclei sometimes

show little relationship to the results of the simple theory and for such cases no determination of spins and parities can be made on the basis of this theory.

Attempts to improve the theory have generated several distorted wave Born approximation (DWBA) theories<sup>3</sup>. The DWBA approach, however, is based on a premise which in my opinion is unjustified<sup>4</sup>. It describes the centre of mass motion of the deuteron by an optical model wave function, but leaves the internal motion unpolarized. Yet it is likely that contributions to stripping reactions arise predominantly from deuterons which

considerably stretched, with one particle interacting on the average much more strongly with the nucleus than the other, so that deuteron distortion effects are in all probability quite crucial<sup>1</sup>. Although it may well be possible to choose optical model parameters to fit deuteron elastic scattering, this does not mean to say that the full deuteron wave function is known, particularly in those configurations relevant in stripping.

These remarks are borne out by actual results of calculation. As a general rule agreement with experimental stripping angular distributions can be obtained in the DWBA theory only by a choice of parameters different from those required in elastic scattering. Moreover, the number of parameters involved is so great that any unique assignment of spins and parities is lost.

I suggest a new approach which appears quite promising, particularly for  $(d,p)$  reactions. This was reported briefly at the 1964 Conference of the Australian and New Zealand Association for the Advancement of Science<sup>4</sup>.

The basic matrix element for a  $(d,p)$  reaction, for example, may be written in the form:

$$I(\mathbf{k}_p, \mathbf{k}_d) = \langle \psi_d^+(\mathbf{k}_d, \mathbf{r}_p, \mathbf{r}_n) | V_{np} | F(\mathbf{r}_n) \psi_p^-(\mathbf{k}_p, \mathbf{r}_p) \rangle \quad (1)$$

Here  $\mathbf{r}_p$  and  $\mathbf{r}_n$  are the neutron and proton co-ordinates respectively,  $\mathbf{k}_d$  is the incident deuteron momentum and  $\mathbf{k}_p$  is the outgoing proton momentum. The wave function  $\psi_d^+$  describes elastically scattered deuterons with outgoing spherical waves,  $\psi_p^-$  describes elastically scattered protons with incoming spherical waves and  $F$  is the wave function of the final bound neutron. The normal neutron proton interaction is represented by  $V_{np}$ . In the form of equation (1) all other nuclear co-ordinates have been integrated out, so that  $\psi_p^-$  may be considered to be a known optical model wave function.

Now we assume, instead of the usual distorted wave, that  $\psi_d^+$  satisfies the equation:

$$(T_n + T_p + V_{np} + V_n + V_p) \psi_d^+ = E \psi_d^+ \quad (2)$$

where  $T_n$  and  $T_p$  are kinetic energy operators and where  $V_n$  and  $V_p$  are optical potentials for neutron and proton, respectively, incident on the initial nucleus. Strictly these are energy dependent and should be considered as operators dependent on the square of the momenta of the particles.

We know that a plane wave deuteron has the following transform:

$$e^{i\mathbf{k}_d \cdot \mathbf{r}} \chi(\mathbf{r}) = \frac{N}{2\pi^3} \int d\mathbf{k}'_p G(\mathbf{k}'_p, \mathbf{k}_d) e^{i\mathbf{Q}' \cdot \mathbf{r}_n} e^{i\mathbf{k}'_p \cdot \mathbf{r}_p} \quad (3)$$

where  $\mathbf{Q}' = \mathbf{k}_d - \mathbf{k}'_p$ . The internal deuteron wave function is written:

$$\chi(\mathbf{r}) = N (e^{-\gamma r} / r - e^{-\zeta r} / r)$$

and:

$$G(\mathbf{k}'_p, \mathbf{k}_d) = \left\{ \frac{1}{(\mathbf{k}_d/2 - \mathbf{k}'_p)^2 + \gamma^2} - \frac{1}{(\mathbf{k}_d/2 - \mathbf{k}'_p)^2 + \zeta^2} \right\} \quad (4)$$

Equation (3) may be discussed in time-dependent terminology in a way which can be instructive. If a 'snap-shot' be taken of a moving deuteron wave packet with an 'exposure time' short compared with the natural period of the deuteron, the neutron and proton would appear to be described by independent wave packets with momenta  $\mathbf{k}'_p$  and  $\mathbf{Q}'$ . The probability for finding given momenta is described by  $G$ .

For deuterons with a sufficiently high momentum involved in a stripping reaction it would seem plausible that any interaction of the neutrons and protons with the initial nuclei might occur in a period small compared with the natural period of the deuteron; this might be particularly the case if the reaction tends to be confined to a surface volume. It could then be a reasonable approach to use a 'sudden' approximation for  $\psi_d^+$  in equation (1) and to write it:

$$\psi_d^+ = \frac{N}{2\pi^3} \int d\mathbf{k}'_p G(\mathbf{k}'_p, \mathbf{k}_d) \psi_n^+(Q', \mathbf{r}_n) \psi_p^+(\mathbf{k}'_p, \mathbf{r}_p) \quad (5)$$

where  $\psi_n^+$  and  $\psi_p^+$  are optical model wave functions for neutron and proton respectively with the appropriate momenta. Thus  $\psi_n^+$  and  $\psi_p^+$  satisfy wave equations:

$$(T_n + V_n) \psi_n^+ = E_n \psi_n^+$$

and:

$$(T_p + V_p) \psi_p^+ = E_p \psi_p^+ \quad (6)$$

with  $E_n$  and  $E_p$  being energies appropriate to the momenta  $\mathbf{k}'_p$  and  $\mathbf{Q}'$  respectively.

We use equation (2) to re-express the quantity  $V_{np} \psi_d^+$  of the matrix element (1) as follows:

$$V_{np} \psi_d^+ = \{E - (T_n + T_p + V_n + V_p)\} \psi_d^+ \quad (7)$$

On now substituting the approximation (5) for  $\psi_d^+$ , and making use of the wave equations (6), the matrix element (1) takes the form:

$$I(\mathbf{k}_p, \mathbf{k}_d) = - \frac{\lambda^2 N}{2\pi^3 m} \int d\mathbf{k}'_p g(\mathbf{k}_d, \mathbf{k}'_p) \langle \psi_p^+(\mathbf{k}'_p, \mathbf{r}_p) | \psi_p^-(\mathbf{k}_p, \mathbf{r}_p) \rangle \langle \psi_n^+(Q', \mathbf{r}_n) | F(\mathbf{r}_n) \rangle \quad (8)$$

where  $m$  is the nucleon mass and:

$$g(\mathbf{k}_d, \mathbf{k}'_p) = \{(\mathbf{k}_d - \mathbf{k}_p/2)^2 + \gamma^2\} G(\mathbf{k}_d, \mathbf{k}'_p) \quad (9)$$

The element  $\langle \psi_p^+(\mathbf{k}'_p, \mathbf{r}_p) | \psi_p^-(\mathbf{k}_p, \mathbf{r}_p) \rangle$  is determinable; it is predominated by a term  $2\pi^3 \delta(\mathbf{k}_p - \mathbf{k}'_p)$ . Thus the predominant term in equation (8) is simply:

$$I(\mathbf{k}_p, \mathbf{k}_d) = - \frac{4\pi N \lambda^2}{m} g(\mathbf{k}_d, \mathbf{k}_p) \langle \psi_n^+(Q, \mathbf{r}_n) | F(\mathbf{r}_n) \rangle \quad (10)$$

Equation 10 is much more amenable to numerical calculation than the usual DWBA approach. It involves a bound state neutron wave function  $F$ , characterized by a given orbital angular momentum  $l$ , and the neutron optical model wave function  $\psi_n^+$ . Thus the angle integrations in equation (10) may be trivially performed leaving a one-dimensional integral over the neutron radial co-ordinate  $r_n$ . Parameters of the radial neutron optical model wave function are appropriate to an energy  $\lambda^2 Q^2 / 2m$  and are therefore different for each angle of scattering. Nevertheless neutron optical model parameters have been well tabulated over large energy ranges, so that equation (10) may be considered to have no unknown parameters except the orbital angular momentum of the bound neutron.

Perhaps the main difficulty of this approach lies in the treatment of the coulomb interaction between proton and nucleus which is not of short range and for which the sudden approximation cannot be expected to apply accurately. To the extent, however, that the main coulomb deviations of the proton occur in the vicinity of the nucleus no serious coulomb error should occur within this formalism, at least for  $(d,p)$  reactions.

In a forthcoming publication<sup>5</sup> by Dr. C. A. Pearson and me it will be shown how equation (8) can be formally derived by means of standard impulse approximation techniques. Numerical calculations are being undertaken by Dr. Pearson and will also be published shortly. Preliminary results of these calculations, which include also the polarization resulting from stripping reactions, appear to be in remarkably good agreement with experiment.

This work was supported in part by the Nuclear Research Foundation within the University of Sydney, and I thank its director, Prof. H. Messel, for his interest.

## A NEW METHOD FOR DEUTERON STRIPPING CALCULATIONS (II)

By DR. ROBERT M. MAY

Dally Telegraph Theoretical Department, School of Physics, University of Sydney

A FEW impulse approximation method for use in deuteron stripping and pick-up calculations has recently been presented by S. T. Butler<sup>1</sup>. This method goes beyond the simple Butler-Born (B-B) approximation<sup>2</sup>, yet is free from the conceptual and methodological difficulties which beset distorted wave Born approximations.

To exemplify the method, Butler considers a  $(d,p)$  reaction. The basic matrix element may be written, in the usual notation<sup>3</sup> and with the nuclear co-ordinates integrated out, as:

$$I(\mathbf{k}_d, \mathbf{k}_p) = \langle F^*(\mathbf{r}_n) \psi_p^-(\mathbf{k}_p, \mathbf{r}_p) | V_{np} | \psi_n^+(\mathbf{k}_d, \mathbf{r}_n, \mathbf{r}_p) \rangle \quad (1)$$

Here  $\mathbf{k}_d$  and  $\mathbf{k}_p$  are respectively the incident deuteron and outgoing proton momenta, and  $F$  is the wave function of the final bound neutron with binding energy  $-E_B$  ( $E_B \equiv \hbar^2 \chi^2 / 2m$ ). The impulse approximation consists of writing the initial deuteron wave function  $\psi_n^+$ , as a momentum space convolution integral between a free deuteron wave function and the optical model wave functions for neutron and proton interacting separately with the nucleus. Then, after some manipulation<sup>1,2</sup>, one obtains the result (the final equation (10) of ref. 1):

$$I(\mathbf{k}_d, \mathbf{k}_p) = -\frac{\hbar^2}{m} g(\frac{1}{2}\mathbf{k}_d - \mathbf{k}_p) \langle F^*(\mathbf{r}) | \psi_n^+(\mathbf{Q}, \mathbf{r}) \rangle \quad (2)$$

Here  $\psi_n^+(\mathbf{Q}, \mathbf{r})$  is the optical wave function for an (outgoing) neutron elastically scattered from the nucleus, with energy  $E(\mathbf{Q}) = \hbar^2 \mathbf{Q}^2 / 2m$ ;  $\mathbf{Q}$  is defined as  $\mathbf{Q} = \mathbf{k}_d - \mathbf{k}_p$ ; and as usual the function  $g(\mathbf{p})$  is:

$$g(\mathbf{p}) = \{p^2 + \gamma^2\} G(\mathbf{p}) \quad (3)$$

where  $G$  is the Fourier transform of the deuteron internal wave function, and the deuteron binding energy is written as  $\hbar^2 \gamma^2 / m$ .

(The B-B result is obtained from (2) by writing  $\psi_n^+$  as a plane wave outside the nucleus, and as zero within.)

In the work recorded here we use a square well for the neutron-nucleus interaction to effect an exploration of the consequences of the approximation (2). The results shed light on the agreements and discrepancies between B-B theory and experiments.

Suppose the optical wave function,  $\psi_n$ , for a neutron elastically scattered by the nucleus is given by the complex potential:

$$\begin{cases} V(r) = V_0 + iV_I; & r < a \\ V(r) = 0 & ; r > a \end{cases} \quad (4)$$

Let the bound state wave function,  $F$ , be given by a real square well potential with the same radius:

$$\begin{cases} U(r) = U_0; & r < a \\ U(r) = 0 & ; r > a \end{cases} \quad (4')$$

By the argument which usually leads to the orthogonality result, we obtain:

$$(E(\mathbf{Q}) + E_B) \int F^*(\mathbf{r}) \psi_n^+(\mathbf{Q}, \mathbf{r}) d\mathbf{r} = \int F^*(\mathbf{r}) \{V(r) - U^*(\mathbf{r})\} \psi_n^+(\mathbf{Q}, \mathbf{r}) d\mathbf{r} \quad (5)$$

We now take the real parts of  $V$  and  $U$  to be equal. In practice,  $V_0 = U_0$ , to within at most a few MeV; such equality is a self-consistency check on the optical model. (The character of the subsequent results is not altered if we allow a difference  $|V_0 - U_0| \approx |V_I|$ .) Equation (5) becomes:

$$(E(\mathbf{Q}) + E_B) \int F^*(\mathbf{r}) \psi_n^+(\mathbf{Q}, \mathbf{r}) d\mathbf{r} = i V_I \int F^*(\mathbf{r}) \psi_n^+(\mathbf{Q}, \mathbf{r}) d\mathbf{r} \quad (6)$$

Rearranging equation (6), we get for the matrix element in equation (2):

$$| \langle F^* | \psi_n^+ \rangle | = \frac{|V_I|}{\{E(\mathbf{Q}) + E_B\}^2 + V_I^2} \left| \int_{r>a} F^* \psi_n^+ d\mathbf{r} \right| \quad (7)$$

For our square well, the radial parts,  $f(r, l, m)$  and  $\varphi_n(r, l, m)$ , of the wave functions  $F(r)$  and  $\psi_n^+(r)$  can be written down for  $r > a$ :

$$f(r, l, m) = A(l, m) h_l(i\chi r) \quad (8)$$

$$\varphi_n(r, l, m) = e^{i\delta_l} \{ \cos \delta_l j_l(Qr) - \sin \delta_l n_l(Qr) \}$$

Here  $h_l$  is the spherical Hankel function of the first kind,  $j_l$  and  $n_l$  are the spherical Bessel functions of the first and second kind, respectively,  $A$  is the same constant which appears in the B-B theory, and  $\delta_l(Q)$  is the (complex) phase shift<sup>4</sup> for the  $l$ -th partial wave.

If the bound state neutron can be characterized by a unique orbital angular momentum quantum number  $l$ , the angle integrals on the right-hand side of equation (7) can be readily performed. Next the properties of Bessel functions can be used to evaluate the radial integral. Choosing the vector  $\mathbf{Q}$  as the polar axis, we can finally write:

$$\int_{r>a} F^*(\mathbf{r}) \psi_n^+(\mathbf{Q}, \mathbf{r}) d\mathbf{r} = \frac{\{4\pi(2l+1)\}^{1/2} a^3}{Q^3 + \chi^2} A(l, 0) e^{i\delta_l} \cos \delta_l [W(j_l(Qa), h_l(i\chi a)) - \tan \delta_l W(n_l(Qa), h_l(i\chi a))] \quad (9)$$

Here  $W$  denotes the Wronskian defined as:

$$W(u, v) = \left\{ u \frac{\partial v}{\partial r} - \frac{\partial u}{\partial r} v \right\}_{r=a} \quad (10)$$

Equations (2) (7) and (9) thus give the matrix element for a  $(d,p)$  reaction in the new approximation. We proceed to comment on the relationship between the present results and the B-B theory, with respect to: (A) absolute magnitudes of cross-sections; (B) angular variation in differential cross-sections; (C) zeros in the differential cross-section.

(A) Returning to my earlier remarks, we observe that the B-B estimate of the matrix element in equation (2) is just the expression in equation (9) with  $\delta_l = 0$ . Thus, from equation (7) we see that in the limit when  $\delta_l = 0$ , the new approximation gives differential cross-sections which differ from the B-B theory only by a factor:

$$\frac{V_I^2}{\{E(\mathbf{Q}) + E_B\}^2 + V_I^2} \quad (11)$$

Since the angle dependence of this factor (contained in  $\mathbf{Q} = \mathbf{k}_d - \mathbf{k}_p$ ) is much weaker than that contained in the Wronskian  $W(j_l, h_l)$ , we may say that if the optical phase shift is small, the new approximation and the B-B approximation will give essentially the same angular distribution, but the new approximation will give an absolute cross-section smaller than the B-B one by the significant factor (11).

This is relevant to the notorious experimental fact that even in the many instances when B-B theory explains the angular distribution excellently, it over-estimates the absolute cross-section by as much as an order of magnitude<sup>5</sup>. Indeed, nuclear reduced widths are extracted by fitting the shape of the B-B angular distribution; such empirical reduced widths are generally smaller than those

calculated by B-B theory by factors which increase from about 2-6 at low binding energies up to about 6-20 at larger binding energies ( $E_B > 10$  MeV). This is the behaviour to be expected from equation (11); the value of  $V_1$ , taken from neutron elastic scattering<sup>4</sup>, is about 3 MeV for  $E(Q)$  around a few MeV.

In Table 1, we take  $E(Q)$  to be around 3 MeV, and display the factor (11) alongside the ratio of empirical reduced widths,  $\theta_s^2$  (exp.), to B-B reduced widths,  $\theta_s^2$  (B-B), for neutron capture into  $2s$  states and for capture into  $1d$  states<sup>5</sup>.

Table 1

Neutron binding energy (MeV)	The factor (11)	$\frac{\theta_s^2(\text{exp.})}{\theta_s^2(\text{B-B})}$ ( $2s$ )	$\frac{\theta_s^2(\text{exp.})}{\theta_s^2(\text{B-B})}$ ( $1d$ )
2	0.25	0.4 (4)	0.1 (5)
7	0.08	0.1 (6)	0.07
12	0.04	0.08	0.05

(B) For a more detailed comparison between equations (7) and (9), and the simple B-B theory, it is necessary to compute  $\delta_l(Q)$  as a function of  $Q = |\mathbf{k}_d - \mathbf{k}_p|$  for any particular ( $d, p$ ) reaction.

For this article we note that for given  $l$ , the modulus of the phase shift is generally small for small  $Q\alpha$  (for example, for  $l = 3$ ,  $\alpha = 4f$ ,  $V_0 = 50$  MeV, then  $|\tan \delta_l| < 0.1$  for  $E(Q) < 13$  MeV). Thus without going into detail we can estimate that the corrections to the B-B angular distributions, which are contained mainly in the term  $\tan \delta_l W(n, h_i)$  in equation (9), will be more significant for higher energies of the incident deuteron, and for larger angles ( $Q = |\mathbf{k}_d - \mathbf{k}_p|$  is then larger for given

$\mathbf{k}_d, \mathbf{k}_p$ ). These remarks accord with experimental tendencies<sup>6,7</sup>.

(C) Finally we note that equation (9) does not permit zeros in the differential cross-section. Such zeros (the zeros of the Wronskian  $W(j, h)$ ) are an unphysical feature of the B-B theory.

To prove this assertion, we write the complex phase shift as  $\tan \delta_l = \alpha + i\beta$ . Then apart from obviously non-vanishing terms, the differential cross-section can be written:

$$\frac{d\sigma}{d\Omega} \propto \frac{1}{(1+\beta)^2 + \alpha^2} [(W(j, h) - \alpha W(n, h))^2 + \{\beta W(n, h)\}^2] \quad (12)$$

This expression has no zeros (unless  $\beta = 0$ , that is, unless  $V_1 = 0$ ).

I thank Prof. S. T. Butler for his advice, and also Prof. H. Messel, director of the Nuclear Research Foundation within the University of Sydney, for his support.

## POTASSIUM-ARGON AGES OF ROCKS FROM JAN MAYEN AND AN OUTLINE OF ITS VOLCANIC HISTORY

By F. J. FITCH

Department of Geology, Birkbeck College, University of London

AND

DR. R. L. GRASTY and DR. J. A. MILLER

Department of Geodesy and Geophysics, University of Cambridge

JAN MAYEN is the most northerly of the volcanic islands which rise from the Mid-Atlantic Ridge. It occupies an isolated position just north of the 70th parallel, some 500 km east of Scoresby Sound in East Greenland. Its maximum dimensions are 54 km  $\times$  16 km; it is elongated in a north-east-south-west direction and is widest at the north-eastern end. The present-day island is a small emergent portion of an extensive submarine volcanic accumulation rising from the crest of the mid-Oceanic ridge on the south-east flank of the central rift. The island is wholly volcanic in origin, and to-day is dominated by one great volcanic mountain, Beerenberg, 2,277 m high, forming the entire northern half of Jan Mayen. The central volcanic vent of Beerenberg has been inactive for several thousand years, but parasitic activity on the flanks has occurred more recently. Eruptions on the southern flank of the mountain were observed in 1732 and 1818, and seismic shocks have been reported frequently. Beerenberg is the most northerly of the world's large volcanic mountains, and its summit is covered by a permanent icefield drained by some 20 radial glaciers. The southern half of the island is a narrow volcanic tableland, nearly 500 m high, built by repeated fissure-controlled eruptions and characterized by strings of trachytic domes.

The first extensive geological reconnaissance of Jan Mayen was made by Wordie in 1921 (refs. 1 and 2). Between 1948 and 1963, a series of British university expeditions have gradually extended detailed geological mapping over most of the island. Their work is described

in accounts by Dollar<sup>3</sup>, Nicholls<sup>4</sup> and Fitch<sup>5-7</sup>. The Norwegian geologist, Carstens, mapped the far south of the island in 1959 (ref. 8) and has discussed the petrology of a number of the trachytic domes<sup>8</sup>. Very little is known of the composition of the submarine bank, but evidence from accidental blocks in agglomerates and tuff-breccias suggests that it is composed of both tholeiitic and alkali-basaltic rocks with related differentiates. The rocks above sea-level, both lavas and pyroclastics, are predominantly of alkali-basalt and picrite, with subordinate amounts of trachybasalt, mugearite and trachyte. Ankaramites (both ultrabasic and basaltic varieties) are very common in some lava sequences, and in this respect Jan Mayen is unique among the volcanic islands of the Atlantic Ocean. The petrology of the rocks is discussed in the papers by Nicholls, Carstens and Fitch already mentioned here, and also in papers by Holmes<sup>9</sup>, Tyrell<sup>11</sup> and Roberts and Hawkins<sup>12</sup>. Notwithstanding the presence of Beerenberg and numerous other central volcanoes, fissure volcanism, both pyroclastic and effusive, is the dominant eruptive mechanism on Jan Mayen. Accounts of the more unusual volcanic phenomena have been given by Dollar<sup>13</sup> and by Hawkins and Roberts<sup>14</sup>.

The geological history of Jan Mayen begins with the building of the submarine bank by extensive basaltic eruptions along and close to the crest of the mid-Oceanic ridge. The age range of this phase in its development is unknown; but, by analogy with Iceland, this phase most probably occurred during mid-Tertiary to Early Pleistocene times. The oldest rocks seen above sea-level are well

exposed along the base of the great sea cliffs between Sorbukta and Ullringbukta in the far south of the island. They consist predominantly of pyroclastic whalebacks and related flows of ankaramitic and trachybasaltic lavas that appear to have been erupted from a fissure swarm aligned close to N. 50° E. This early phase of emergence was followed in South Jan by a period during which an extensive plateau of trachybasaltic and less basic lavas was erupted from an intersecting network of fissure swarms, the older N. 50° E. set and a new N. 40° E. swarm. North Jan and the proto-Beerenberg began to grow where this new and powerful fissure-swarm was intersected by a major cross-fault. This, possibly rather lengthy, period was brought to a close by the intrusion of numerous trachytic plug domes sealing the principal volcanic throats. For some time after the intrusion of the trachytic domes, volcanism on Jan Mayen was much reduced in intensity. During this interval, extensive erosion occurred throughout the island and a large ice-cap formed on the proto-Beerenberg. Tillites or fluvioglacial deposits of this age are found throughout the island. As the massive tillites of this time are the only evidence of major glaciation known from Jan Mayen, it has been assumed that they were formed during the last maxima of the Pleistocene (see the arguments in ref. 6). If this is a correct assumption, then the preceding volcanism must have occurred within the Pleistocene, unless evidence of previous maxima is missing.

In the period immediately following the deposition of the tillite sheets, erosion continued to be more important than volcanism in South Jan. The principal focus of activity moved north-eastwards to the Beerenberg and the major part of the mountain was constructed in four successive stages.

First, a series of explosive fissure eruptions occurred along the N. 40° E. fissure swarm, especially along the north-east ridge of Beerenberg, extending the mountain considerably in that direction. On the south flank of the mountain, sub-glacial hyaloclastic tuffs<sup>18</sup> indicate that ice was still present on the proto-Beerenberg at the beginning of this stage. In the second stage a gigantic ash-flow eruption from the central vent deposited a thick sheet of basic pumice siller on the southern flanks of the mountain. The third stage was a prolonged period of Hawaiian-type volcanism from the central vent which resulted in the development of a large ankaramitic basalt shield volcano. Finally, after a short erosion interval, a large composite trachybasaltic lava cone was built on the summit of the lava dome, completing the major part of Beerenberg. The formation of the summit cone was followed by an important erosion interval during which extensive sea-cliffs developed all around Jan Mayen.

There have been two major phases of volcanism subsequent to the formation of the summit cone, both entirely fissure-controlled. At first volcanism was related to the N. 40° E. fissures which became active again throughout the island except across the higher parts of Beerenberg. A number of radial fissures were active, however, on the

south-west and south flanks of the mountain during this episode. This fissure volcanism was both ankaramitic and trachybasaltic in character. It frequently consists of extensive and violent pyroclastic eruption followed by quiet lava effusion. Throughout Jan Mayen great pyroclastic ridges were built along fissure lines, and lava streams flowed into the intervening depressions and spread over existing cliffs to make coastal laval platforms. During the later phase of this post-Beerenberg volcanism an additional fissure trend at N. 65° E. became apparent especially in the far north-east of the island. A study of Jan Mayen geomorphology and of the history of growth and decay of the Beerenberg icefield over the past 10,000 years suggests that the high summit cone was completed at least 5-6,000 years ago and that the most important subsequent volcanic episodes occurred between 4-5,000 and 2,500-3,500 years ago (see arguments in ref. 6 and 15-18). The coastal lava platforms of the latter episode sit on a widespread post-glacial raised beach.

The age estimates referred to here were made in 1963 after consideration of the available geological and geomorphological evidence, and are necessarily based on a number of unproved assumptions. Recent discussion of Continental Drift and of the evolution of the Atlantic Ocean by Wilson<sup>19,20</sup>, Miller and Fitch<sup>21</sup> and others has made it essential for accurate age information to be obtained from the volcanic islands of the Atlantic.

This investigation of the most northerly of the volcanic islands on the mid-Ocean ridge was undertaken as a test of the methods to be used. It is intended that it should be the first of a number of such investigations. A stratigraphically representative collection of some fifty Jan Mayen rocks was made by Fitch during the 1963 Imperial College Beerenberg Expedition. From this stratigraphical collection ten rocks were selected for potassium/argon age determination by omegatron. The instrument has recently been described by Grasty and Miller<sup>22</sup>. To minimize possible errors introduced by any serial changes in potassium content that might occur, especially in flow-aligned igneous rocks, each specimen was cut into three parallel slices using a diamond saw. The rocks were examined petrologically in thin sections cut at right angles across the direction of slicing. Potassium oxide contents were determined in the two outer slices and an average value calculated. Two independent argon determinations were then made on the inner slice.

The results of potassium/argon age measurements on the three geologically oldest rocks are listed in Table 1. As the youngest two rocks of this sequence were found to be too young to produce a satisfactory potassium/argon age, it was obviously impracticable to attempt the analysis of the even younger specimens, and, therefore, this has not been done. The oldest rock analysed was SJ 1, an olivine-basalt lava flow exposed at the base of the cliffs at the far southern end of Sorbukta. In thin section it is seen to be an unaltered, strongly flow-aligned, olivine-basalt, in which small microporphyritic groups of olivine and, much more rarely, augite (occasionally associated

Table 1. NW POTASSIUM/ARGON AGE DETERMINATIONS

		1.21	> 99.5	—	Less than 0.09

$$\lambda_8 = 4.72 \times 10^{-10} \text{ y}^{-1}, \quad \lambda_6 = 0.584 \times 10^{-10} \text{ y}^{-1}.$$

with plagioclase) are carried in a matrix of labradorite laths with interstitial augite, olivine and iron ores.

The next oldest rock was *SJ 9*, a vesicular lava flow of ankaramitic basalt exposed at the base of the vertical cliffs in the middle of Ullringbukta. In thin section it is seen to consist of euhedral augite and olivine phenocrysts set in a fine-grained matrix of minute plagioclase laths, pyroxene and iron ores, which encloses also numerous small microphenocrysts of augite and olivine. Widespread iddingitization of the marginal zones of olivine crystals is probably deuteric in origin and does not necessarily indicate that any significant argon loss from the feldspars or pyroxenes has taken place. The feldspars and pyroxenes are quite fresh and unaltered. Both these rocks belong to the earliest phase of emergence of Jan Mayen. The volcanic formation of which they are members is the older of the two pre-tillite volcanic sequences of South Jan. The ages obtained fall in the range 500,000 to less than 30,000 years; the better determination, that of *SJ 1*, suggests an age of  $400,000 \pm 80,000$  years for that rock. *SJ 9* must be considerably younger, certainly less than 240,000 years old, but exactly how young it is cannot be determined as yet with absolute certainty.

The same age arguments apply to *SJ 15*, an absolutely fresh ankaramite lava flow exposed immediately below the tillite in Kroesbukta, North Jan. Stratigraphically, it is at the top of the two pre-tillite sequences of Jan Mayen. In thin section the rock is seen to consist of numerous euhedral olivine and augite phenocrysts set in a fine-grained pyroxene-rich matrix of labradorite, pyroxene, olivine and iron ore. The potassium/argon evidence suggests that *SJ 15* is younger than either *SJ 1* or *SJ 9*, certainly less than 190,000 years old and possibly much younger. All these rocks are Pleistocene in age. The latest evidence from Africa and America suggests that the Pleistocene Period lasted from between 2.5 and 1.5 m.y. to about 10,000 years ago. The rocks of the oldest

part of Jan Mayen would therefore appear to belong to the upper part of the Pleistocene.

The potassium/argon age investigation reported in this article confirms the conclusions reached by geological interpretation, that is, that the emergent part of Jan Mayen began its development in late Pleistocene times, and that the majority of the visible rocks are very young, mostly post-Pleistocene in age. This conclusion is further strengthened by the absence of reversed magnetization among the post-tillite lava sequences of Beerenberg sampled in 1961 and 1963 (ref. 7, and work in preparation). It suggests that volcanism on Jan Mayen is closely related in time to the latest Pleistocene and Recent volcanism in Iceland. At present the combined evidence from Jan Mayen and Iceland appears to be compatible with the hypothesis of ocean floor spreading, for in this region the youngest rocks are certainly found closest to the central parts of the mid-Oceanic ridge.

## TWO NEW TAXA OF THE GLOBOROTALIINAE (GLOBIGERINACEA, FORAMINIFERA) ASSISTING DETERMINATION OF THE LATE MIOCENE/MIDDLE MIOCENE BOUNDARY

By DR. F. T. BANNER and DR. W. H. BLOW

BP Research Centre, Sunbury-on-Thames, Middlesex

THE proposed Swansea symposium, to be held jointly by the Palaeontological Association and the Geological Society of London, will review the fossil record and provide a summary of present knowledge of the ranges of fossil organisms in geological time. In order to provide a biostratigraphical sub-division of the Neogene as a framework for this purpose, as proposed by the Comité du Néogène<sup>1</sup>, research in the Palaeontology Branch, Exploration and Production Research Division of the BP Research Centre, Sunbury-on-Thames, has been directed towards the establishment of a sequence of zones based on the ranges of planktonic foraminifera. This sequence of zones has been compiled from evidence obtained from many areas (for example, Trinidad, Jamaica, Barbados, Venezuela, Italy, Sicily, Malta, Libya, Tanganyika, West Irian, Papua and New Zealand), is being related to the succession of other fossil faunas, and is being correlated, so far as is possible, with the European standard stages. This preliminary account is intended to outline the distinction between the planktonic foraminiferal zones which are believed to permit the determination of the boundary between the Middle Miocene (Tortonian) and the "Upper Miocene" (Late Miocene, Messinian) in circum-equatorial areas of the world.

A total of twenty-three zones, based on planktonic foraminifera, will be proposed to sub-divide the geological

succession from the Early Miocene to the Holocene. Of these zones, Zone N.16 is believed to comprise the late Middle Miocene and Zone N.17 is believed to represent the early part of the Late Miocene. The base of Zone N.16 is defined by the first evolutionary appearance of *Globorotalia* (*Turborotalia*) *acostaensis* (*sensu stricto*) Blow, 1959, which occurs at virtually the same horizon as the first evolutionary appearance of *Globorotalia* (*G.*) *morotumida*, n.sp. The top of Zone N.16 is placed immediately below the first evolutionary appearance of *Globorotalia* (*G.*) *tumida pleiotumida*, n.sub-sp., which defines the base of Zone N.17. The presence of these zones may be recognized on the occurrence of other species, for the stratigraphically earliest *Candolina nitida* (*sensu lato*) appears just below the base of Zone N.16, and *Globorotalia* (*Turborotalia*) *acostaensis humerosa* (Takayanagi and Saito) and *G.(T.) crassaformis* (*sensu stricto*) (Galloway and Wisler) both first appear just below the base of Zone N.17. The boundary between the two zones is taken at the first evolutionary appearance of *Globorotalia* (*G.*) *tumida pleiotumida* from *G.(G.) morotumida* because such evolutionary lineages are believed to provide the most reliably isochronous datum-planes in biostratigraphy<sup>2,3</sup>.

The succession of Zones N.16 and N.17 has been recognized by us to occur in the Pozón section<sup>4</sup>, eastern Falcón, Venezuela, in the lower part of the type Bowden formation

(at present being re-described by E. Robinson, University of the West Indies, Mona, St. Andrew, Jamaica), Jamaica, in the Sarimi formation of the Sarimi region, West Irian, in the Muruan and Toa mudstone succession of western Papua\*, and in a sub-surface section in Somalia. The Tortonian succession at Rio Mazzapiede-Castellania, Italy, has been sampled by D. D. Bayliss (British Museum, Natural History) and the Units 2-4 of Gino\* have been found to comprise Zone N.16, the Zone N.17/N.16 boundary occurring there near the top of the section, very near the top of Unit 4. The sub-surface successions penetrated in the Cubagua wells Nos. 1 and 2, which were originally studied by J. P. Beckmann (in Kugler\*), have been re-examined, and the cored samples from well Cubagua No. 2 have provided the sequence of foraminiferal assemblages which are used as paratype for these zones. The detailed biostratigraphy of these wells, and of the other stratigraphical sections referred to here, will be described later with the full account of the complete succession of Neogene planktonic foraminiferal zones. A horizon referred to the lowest part of Zone N.16 yielded assemblages of specimens morphologically intermediate between *Globorotalia* (*Turborotalia*) *languensis* Bolli and *G.(G.) merotumida* n.sp. The morphological transition between *G.(G.) merotumida* and *G.(G.) tumida plesiotumida* n.sub-sp. occurs at the base of Zone N.17. *G.(G.) tumida tumida* first occurs at the base of Zone N.18, where it is associated with morphologically intermediate forms from *G.(G.) tumida plesiotumida*. This evolutionary sequence, from *G.(T.) languensis* to *G.(G.) tumida tumida*, parallels the analogous evolution, in the Early Miocene, of *G.(G.) lobata robusta* (Bolli) from *G.(T.) fohsi barisanensis* (LeRoy)\*; in each case, a species of carinate *Globorotalia* (s.s.) evolved from *G. (Turborotalia)* with concomitant increase in test-size, and the evolution within the forms referable to *Globorotalia* (s.s.) in each case led to the development of more tumid tests with massive carinae.

*Globorotalia* (*G.*) *merotumida* Blow and Banner n.sp. (Figs. 1a-c).

**Description of holotype**<sup>14</sup>. The test consists of three whorls of regularly enlarging chambers, six in each whorl; successive whorl heights are in the approximate ratios 1 : 2 : 5. The test is completely evolute dorsally, and the dorsal walls of all the chambers are thin, translucent and finely perforate; there is no conspicuous deposit of thick, secondary laminae to obscure the early whorls. The

dorsal surface is slightly convex, but the dorsal chamber walls are but little, if at all, inflated; the dorsal sutures are very weakly depressed, but they are marked by continuously developed, slightly raised sutural limbations of clear, imperforate shell material. The spiral suture is lobulate. The globular proloculus (c. 0.015 mm diameter) is surrounded by a whorl of reniform chambers with smoothly curved intercameral sutures; in succeeding whorls, the intercameral sutures become straighter and are, in their mid-parts, oblique to the weakly lobulate spiral suture at angles of about 45°; however, the proximal ends of the later intercameral sutures may be sharply re-curved, meeting the spiral suture virtually at right angles. The axial periphery is acute and is furnished, throughout ontogeny, with an imperforate carina, which is continuous with the dorsal sutural thickenings. In axial profile, the chambers are slightly concave immediately dorsally and ventrally to the carina. The ventral surface of the test is much more strongly convex than the dorsal surface, the ratio of ventral to dorsal convexity being about 2 : 1. The ventral side is completely involute, only six chambers being visible. The ventral intercameral sutures are narrowly and shallowly depressed and, throughout most of their length, are nearly straight (or only very slightly curved) and radially arranged, meeting the weakly lobulate periphery and the narrow, closed umbilicus at right angles. The ventral chamber walls are very finely perforate; the pores, being spaced at distances no greater than 0.005 mm, are approximately equal in size and density of distribution to those on the dorsal surface. Most of the ventral surface is smooth, but granules are developed in the immediate vicinity of the umbilicus on the earlier chambers and on the area of the wall of the first two chambers which immediately faces the aperture. The last-formed chamber possesses a very low, rounded umbilical shoulder; the umbilical shoulders of the earlier chambers are concealed by embracing overlap of the succeeding chambers. The apertural face is flattened and broad; it is broadest near the axial periphery, where it is delimited by the carina, and narrowest near the umbilicus; at its mid-point, the breadth of the apertural face is approximately equal to two-thirds of its total length. The apertural face is separated from the ventral face of the last chamber by an abrupt change in slope, but the area of the change in slope is rounded (not sharply angular), and the texture and structure of the apertural face and the ventral wall are very similar.

The narrow, interiomarginal aperture extends from the umbilicus to the ventral margin of the peripheral carina, and it is of approximately uniform breadth throughout. The aperture is furnished, through its length, by a thick, narrow lip, which is most strongly developed towards the umbilicus. The maximum diameter of the test is 0.38 mm.

**Provenance of holotype**: from a core taken at 2,700 ft. depth, well Cubagua No. 2, Island of Cubagua, Venezuela; "*Globorotalia menardii*/*Globigerina nepenthes* zone" of Blow, 1959; paratype locality and level for Zone N.16, *Globorotalia* (*Turborotalia*) *acostaensis*/*Globorotalia* (*G.*) *merotumida* Zone of Blow and Banner, MS; Middle Miocene (Tortonian).

**Depository of holotype**: British Museum (Natural History) No. P45684.

**Comparative diagnosis of species**: *Globorotalia* (*G.*) *merotumida* typically differs from *G.(G.) tumida plesiotumida* in possessing (1) a test which is smaller in size at the same growth stage as measured by the numbers of chambers present, (2) a slower increase in whorl height as seen dorsally, (3) more uniformly enlarging chambers, (4) more consistently oblique dorsal intercameral

Fig. 1. a-c. *Globorotalia* (*G.*) *merotumida* n.sp., dorsal, axial and ventral views of holotype ( $\times 45$ ).

Fig. 2. a-c. *Globorotalia* (*G.*) *tumida* (Brady) *plesiotumida* n.sub-sp., ventral, axial and dorsal views of holotype ( $\times 45$ ).

Fig. 3. a-c. *Globorotalia* (*G.*) *tumida* (Brady) *sensu stricto*, ventral, axial and dorsal views of hypotype ( $\times 45$ ).

sutures, (5) a thinner and more finely perforate test wall, (6) a thinner carina, (7) a relatively greater ventral convexity, and (8) a relatively broader apertural face. *G.(G.) merotumida* differs from *G. (Turborotalia) languensis* Bolli in possessing (1) a clearly developed imperforate peripheral carina, (2) a test which has about 25 per cent greater diameter at the same growth stage, as measured by the number of chambers present, (3) a more rapidly increasing whorl height, and (4) less strongly curved dorsal intercameral sutures. *G.(G.) merotumida* has a much more convex and tumid test than any sub-species of *G.(G.)* *ultrata* (s.l.) (d'Orbigny). *G.(G.) unguata* Bermúdez, although possessing a dorso-ventral convexity comparable with that of *G.(G.) merotumida*, has a much weaker carina, circumferentially longer chambers in dorsal aspect, a shorter aperture, and a much more rapid increase in whorl height.

*Globorotalia (G.) tumida* (Brady)

*Globorotalia (G.) tumida* (Brady) *sensu stricto* (Fig. 3a-c). *Pulvinulina menardii* (d'Orbigny) var. *tumida* Brady, 1877, *Geol. Mag.*, n.s., dec. 2, vol. 4, p. 535; Brady, 1879, *Quart. Jour. Micr. Sci.*, vol. 19, n.s., p. 80.

*Pulvinulina tumida* Brady, 1884, *Rept. Voy. Challenger*, Zool., vol. 9, Pt. 22, p. 692, pl. 103, Figs. 4-6.

*Globorotalia tumida* (Brady), Cushman, 1927, *Contr. Cushman Lab.*, vol. 3, p. 91, pl. 19, Fig. 12; Bolli, Loeblich and Tappan, 1957, *U.S. Nat. Mus. Bull.*, 215, pp. 41-42, pl. 10, Figs. 2a-c; Banner and Blow, 1960, *Contr. Cushman Fdn.*, vol. 11, pp. 26-27, pl. 5, Fig. 1a-c.

*G.(G.) tumida tumida*, as here restricted by the separation of its ancestral sub-species (*G.(G.) tumida plesiotumida*), first appears at the base of Zone N.18, the zone which, in its lower part, is believed to represent the late Messinian. *G.(G.) tumida tumida* is nominally validated by its described and illustrated lectotype<sup>10</sup> and paralectotype<sup>11</sup>, both of which were originally obtained from the "post-Tertiary" (probably Pliocene or latest Miocene) of New Ireland; *G.(G.) tumida tumida* has also frequently been recorded and illustrated from recent seas<sup>12-14</sup>.

The specimen of *G.(G.) tumida tumida*, illustrated here for comparison with *G.(G.) tumida plesiotumida*, was obtained from the lower part of Zone N.18, latest Miocene, from a section in the Moencok River, West Irian (sample Su 596).

*Depository of hypotype*: British Museum (Natural History) No. P45685.

*Globorotalia (G.) tumida* (Brady) *plesiotumida* Blow and Banner n.sub-sp. (Fig. 2a-o).

*Description of holotype*<sup>14</sup>. The test consists of three whorls of chambers; the successive whorl heights are in the approximate ratios 1:4:8. The test is completely evolute dorsally and the dorsal walls of all the chambers are translucent and uniformly perforate; the dorsal surface of the early whorls is clearly thickened by secondary laminae, but the surface is smooth, not pustulate, and the perforation distribution and density is not appreciably affected, nor is the chamber arrangement obscured. The dorsal surface is smoothly convex, but the dorsal chamber walls are uninflated. The dorsal intercameral sutures are very weakly depressed between the last two or three chambers only; the sutures between the earlier chambers are flush with the surface of the test (because of the laminal thickening) but are marked by continuously developed, flush or very slightly raised, sutural limbations of imperforate, clear shell material. The globular proloculus (c. 0.010 mm diameter) is surrounded by a whorl of five reniform chambers, with smoothly curved intercameral sutures. The succeeding whorl, of six chambers, possesses straighter intercameral sutures, which are oblique to the very weakly lobulate spiral suture at angles of about 45°. The proximal ends of the later sutures become increasingly re-curved, so that in the last whorl (of 6+ chambers) the inner ends of the intercameral

sutures are approximately sub-radial, only their distal parts being curved to meet the periphery obliquely. The axial periphery is acute and is furnished, throughout ontogeny, with an imperforate carina which is continuous with the dorsal sutural limbations. In axial profile, the last-formed chamber is slightly concave immediately ventrally to the carina. The ventral surface of the test is slightly more strongly convex than the dorsal surface, the ratio of ventral to dorsal convexity being about 3:2. The ventral side is completely involute, only the six and one-half chambers which comprise the last whorl being visible. The ventral intercameral sutures are narrowly and shallowly depressed, are nearly straight or very slightly curved or sinuous, and are radially arranged, meeting the weakly lobulate periphery and the narrow, almost completely closed umbilicus approximately at right angles. The ventral chamber walls are finely and uniformly perforate, the pores, being spaced at distances no greater than 0.01 mm, being approximately equal in size and density of distribution to those of the dorsal surface. Most of the ventral surface is smooth, but granules are developed in the immediate vicinity of the umbilicus on the four earlier chambers of the last whorl as well as on areas of the walls of the first two chambers which immediately face the aperture. The last-formed chamber possesses a low, rounded umbilical shoulder; this shoulder is visible, to a decreasing extent, on the two preceding chambers, but it is concealed on earlier chambers of the last whorl by intercameral embrace and overlap. The apertural face is flattened and broad; it is broadest near the axial periphery, where it is slightly concave and is delimited by the carina, and narrowest near the umbilicus; at its mid-point, the breadth of the apertural face is approximately equal to one-half its total length. The apertural face is separated from the ventral face of the last chamber by a change in slope; the area of the change is rounded (not sharply angular), and the texture and structure of the apertural face and the ventral wall are very similar. The narrow, interiomarginal aperture extends from the umbilicus almost to the ventral margin of the peripheral carina; the aperture, which is a low arch, broadest just dorsal to its mid-point, is furnished, throughout its length, with a narrow, uniformly developed lip. The maximum diameter of the test is 0.52 mm.

*Provenance of holotype*: from a core taken at 1,400 ft. depth, well Cubagua No. 2, Island of Cubagua, Venezuela; "Sphaeroidinella seminulina Zone" of Blow, 1959; paratype locality and level for Zone N.17, the *Globorotalia (G.) tumida plesiotumida*/*Globorotalia (Turborotalia) crassaformis* Zone of Blow and Banner, MS; Late Miocene (Messinian).

*Depository of holotype*: British Museum (Natural History) No. P45683.

*Comparative diagnosis of sub-species*: *Globorotalia (G.) tumida (sensu stricto)* differs from *G. (G.) tumida plesiotumida* in developing a much larger test at the same growth stage (as determined by the number of chambers attained), with a much more rapid increase in whorl height (successive whorl heights being in the approximate ratios 1:4:12). *G.(G.) tumida tumida* also characteristically differs from *G.(G.) tumida plesiotumida* in possessing a much more massive carina, thicker test walls, a greater development of coarse granules on the earlier chambers of the ventral side, a tumid test of approximately equal dorso-ventral convexity (that is, dorsal height/ventral depth being in the approximate ratio 1:1) and often in possessing a higher aperture, furnished with a very broad, thick lip.

## MICROBIAL AND RESIDUAL MYCOSTASIS IN SOILS

By DR. C. G. DOBBS and M. J. GASH

University College of North Wales, Bangor

IN 1953, Dobbs and Hinson<sup>1</sup> described a widespread inhibition of fungal spore germination and hyphal growth in soils, now commonly referred to as soil myco-stasis or fungistasis. Further work in many parts of the world has since confirmed the general occurrence of this phenomenon in surface soils, and its complex, mainly microbial, origin, although there is still much discussion about the mode of action and the identity of the organisms concerned.

Many organisms, bacteria, actinomycetes and fungi, have been shown to produce, when cultured on agar media or autoclaved soil, an inhibition of the germination of test spores or the growth of hyphae separated by agar or cellulose film from the culture, or directly in contact with it; but before any of these can be shown to produce myco-stasis in natural soils, their active growth in such soils must be demonstrated.

The restoration of myco-stasis by re-infection of autoclaved soil from natural soil provides no clear evidence, since autoclaved soil may be a relatively rich and artificial medium. Possibly the nearest approach to a demonstration of the involvement of particular micro-organisms in a naturally induced soil myco-stasis was that provided by Dobbs, Bywater and Griffiths<sup>2</sup>, who showed that myco-static properties were restored to a neutral, acid-washed dune sand, both by natural aerial infection and by inoculation from untreated sand or soil. The only organisms which could be isolated from the re-infected sand were bacteria, of which only the Gram-negative isolates were inhibitory in agar culture to the test spores.

However, despite the difficulties in identifying the organisms responsible for the phenomenon in any given soil, there can be no doubt that this type of soil myco-stasis is associated with the presence of soil micro-organisms, and may be referred to as 'microbial myco-stasis'. It is characterized by its complete removal by autoclaving and all sterilizing agents, its continued absence so long as sterile conditions are maintained, its absence also from naturally sterile or near-sterile sub-soils, and by its temporary masking by the addition or presence of certain nutrients, notably sugars, and organic soil amendments, including those liberated by partial sterilization. Though the inhibitory substance or substances concerned have not been identified, when obtained in sterile filtered soil extracts, or in sterile agar disks, they have been shown to be thermolabile.

This distinction is necessary in view of the occurrence of a more stable type of inhibition, first observed in several of a collection of about 40 soil samples from England and Wales examined at Bangor in 1957-58 (ref. 3). In these the inhibition did not react to glucose and survived autoclaving. The soils in question were all calcareous, varying from marine sands containing about 4 per cent to chalk and limestone sub-soils with more than 90 per cent calcium carbonate. Since these soils, where tested, could be shown to give rise to the microbial type of inhibition in sterile, neutral sands, they must be assumed to possess both types

of myco-stasis: the unstable microbial type, and the stable type which remains after that has been removed by sterilization. This thermostable and non-sugar-sensitive type of inhibition is therefore referred to as 'residual myco-stasis' and has been the subject of recent study at Bangor.

The marine sands of Newborough Warren, Anglesey, were chosen for the main investigation in the hope of simplifying the problem by the use of simple soils. Samples from all the ecological zones of the Warren, when tested by the cellulose film method<sup>4</sup> with spores of *Mucor ramannianus*, were strongly myco-static, as they were also to a range of other fungi, including some isolated from the sand. After autoclaving, certain samples supported growth on the test films. All these came from the fixed dunes or the *Salix* slack associates, which had accumulated an appreciable organic content. All the sands which were deficient in organic matter, that is, those from the mobile dunes and the sea strand, exhibited a strong residual inhibition after autoclaving, giving zero germination on the test films.

Fig. 1 shows the average percentage germination (based on 6 experiments with 25 replications each) of test spores of *Mucor ramannianus* on water agar disks. These were first incubated at 21° C for 48 h, with a 'Cellophane' separator to maintain sterility: A, on autoclaved dune sand; B, on acid- and water-washed, neutral, control sand, re-infected with untreated dune sand; C, on uninfected, neutral, control sand. The disks of each series were then exposed for 10 min, in air, to a range of temperatures of 20° C-85° C in a water-bath, before, finally, the spores were added and tested for germination. The marked difference between the graphs for A and B clearly illustrates the relative thermostability of the residual inhibitor

Fig. 1. Germination of spores of *Mucor ramannianus* on sterile water-agar disks pre-incubated on dune sands. Effect of temperature (5-10 min exposure) on: A, residual myco-stasis in autoclaved sand; B, microbial myco-stasis in re-infected, neutral 'control' sand; C, non-mycostatic control on acid- and water-washed, sterile, neutral sand.

and the breakdown of the microbial inhibitor when exposed to temperatures above 50° C. These results would also seem to eliminate competition for nutrients as the main causal factor in soil mycoastasis, at least as demonstrated in these sands—a suggestion which arises from time to time, and has recently been revived by Lockwood<sup>4</sup>.

The residual mycoastasis of the heat-sterilized dune sand was unaffected by extensive washing in up to 40 times its volume of hot water, or by the addition of glucose in solution to the sand. Sand sterilized with alcohol also showed a similar mycoastasis. These preliminary tests, therefore, were taken to have eliminated the autoclaving process, and also sea-salt or other simple and highly water-soluble constituents of the sand, as causal factors; while the absence of a counter-inhibitory effect from the addition of glucose suggested that the effect of organic matter is not to be attributed to its sugar content.

On the other hand, washing or leaching the sand with dilute hydrochloric acid, followed by water-washing until the pH was restored to within the range 5–8, was effective in completely removing the inhibition, leaving a neutral 'control' material, neither inhibitory nor stimulatory to spore germination, on the cellulose film.

Constituents regularly detected in the acid leachate were calcium, ferrous and ferric iron, sodium, potassium, phosphate and nitrate. The effects on spore germination were investigated of the addition of laboratory chemicals to neutral 'control' sand, these being chosen to match so far as possible those found to be present, and added both singly, and in various combinations, in the proportions naturally present.

The progressive addition of 'AnalaR' CaCO<sub>3</sub> to 'control' sand was ineffective in reducing appreciably the germination of test spores of *Mucor ramannianus* until levels of about 30 per cent w/w were reached, inhibition being complete when the mixture contained more than 70 per cent CaCO<sub>3</sub> (Fig. 2). The level of calcium carbonate in Newborough Warren sands is about 4 per cent and never exceeds 8 per cent, so that it is evident that this constituent, though capable of inducing a complete residual mycoastasis at high concentrations, could not be responsible for that found in the Warren sands.

Of the remaining constituents of the acid leachate, only iron was present in appreciable quantities (0.5–1.2 per cent). All the artificial mixtures containing inorganic ferrous or ferric iron, at levels comparable to those found, were inhibitory to some extent to spore germination, while controls containing the same acid radicals with no iron were not, the ferric iron being more active than the ferrous. None of the mixtures lacking iron (or high levels of calcium carbonate) was inhibitory.

However, the inorganic iron compounds, such as ferric chloride, oxide, hydroxide and citrate, ferrous hydroxide,

Fig. 2. Effect of calcium carbonate on germination of spores of *M. ramannianus* on water-agar disks pre-incubated on a range of mixtures of 'AnalaR' CaCO<sub>3</sub> with neutral 'control' sand.

Fig. 3. Effect of chelated iron on germination of spores of *M. ramannianus* on water-agar disks pre-incubated on mixtures of 'control' sand with a chelating agent (EDTA): A, containing iron in sodium/ferric/EDTA compound expressed as per cent iron w/w added to sand; B, controls containing no iron but equivalent amounts of disodium EDTA. Both unbuffered; pH 5.9–6.0.

Fig. 4. As in Fig. 3, but both mixtures buffered to pH 8.5 liberating iron from the chelating bond.

sulphate and ferrous ammonium sulphate, tend strongly to alter the pH when added to 'control' sand. The effect was therefore tested of adding the iron to the 'control' sand in chelated form, as the ferric sodium salt of sequestric acid (EDTA). Fig. 3 shows in graph B the effect of adding increasing quantities of the disodium salt of EDTA to control sand, resulting in a slight fall in germination, at present unexplained. Graph A gives the corresponding curve for the ferric sodium salt, resulting in a greater fall, from more than 90 to about 50 per cent germination. In this case the ferric salt was unbuffered, resulting in a fall of pH from 5.9 to 5.0, the controls following a closely similar range of pH. At this pH the chelating bond presumably would remain intact.

Fig. 4 shows the results of a similar experiment in which the EDTA/sand mixtures were buffered with sodium hydroxide to a pH of 8.5. In graph B (disodium salt control), the germination falls slightly as in Fig. 3, graph B; but in graph A (ferric sodium salt of EDTA) the fall is much more pronounced than in Fig. 3 and germination approaches zero at all levels above 1 per cent iron (w/w). At this pH the ferric/EDTA bond will be broken, liberating free iron. This would appear to confirm the hypothesis, based on the experiments with inorganic iron compounds, that the iron content of the sand is responsible for its residual mycoastasis. Samples of a relatively pure Barton sand from the New Forest which were found to have a very low iron content have been found to possess no residual mycoastasis, or, occasionally, to reduce germination

slightly. On the other hand, an Old Red Sandstone soil which was lacking in residual mycoestasis was also found to have a considerable organic content. When this was leached with NaOH and Na<sub>2</sub>CO<sub>3</sub>, it showed a moderate degree of inhibition. A recent paper by D. A. Griffiths<sup>5</sup> reports residual mycoestasis in a red latosol in Malaya.

The addition of the chelating agent (the disodium salt of EDTA) to mobile dune sand was found to modify its residual mycoestasis, though not completely to abolish it; germination being increased from 0 to the region of 50–70 per cent, as compared with 94 per cent for neutral washed sand. A similar result was obtained by the addition of organic material, mechanically separated from the fixed sand of a wet slack, to the mobile dune sand, both when autoclaving followed and when it preceded the making of the mixture. The indication would therefore seem to be that the organic material removes the free iron by chelation, an effect which is known in other connexions. For example, the fertilizing effect of a lignite on mustard plants has been related to its chelating effect on iron, which is then rendered available for absorption by the plant<sup>6</sup>.

Work on residual mycoestasis in calcareous soils, mainly from the limestone areas near Penmon in Anglesey, indicates two potential sources of the inhibition. When the CaCO<sub>3</sub> level is high, as in the powdered limestone subsoil, this in itself would seem to account for the inhibition, as indicated by the data graphed in Fig. 2. This situation, however, may be modified by the presence of a high humus content, and further complicated by the presence of iron. In certain soils under grass, over carboniferous limestone, the removal of most of the humus by mechanical and chemical means, before sterilization, resulted in a drop in germination from 90 per cent to 35–40 per cent, with a minimum of 15 per cent. In these cases removal of the calcium carbonate did not appreciably increase germination, but subsequent leaching with a chelating agent did, raising the germination level to about 70 per cent.

Though we found it convenient to continue to use as our main test fungus *Mucor ramannianus*, a species usually found in acid soils, but with a germination rate not

appreciably affected by pH within the range found in natural soils, other fungi, including some isolated from the alkaline sands, have also been tested. These have shown broadly similar results, although, in the case of the limestone inhibition, the shape of the germination curve may vary somewhat with the fungus used.

It would thus appear that both calcium carbonate and iron may contribute to the residual mycoestasis found in these soils. There remains also a probability that other inorganic materials, either naturally present or artificially added, may later be found to be responsible for a similar condition in other soils.

There are indications also that the microbial type of inhibition may also be of several kinds; for instance, the 'toxic' surface soil of Gore Heath, near Wareham, Dorset, first described by Rayner and Neilson-Jones<sup>7</sup>, possesses a thermolabile inhibition which is less sensitive to the addition of glucose than is that responsible for the ordinary widespread soil mycoestasis<sup>8</sup>. Information from other workers, mainly unpublished, seems to show that, especially with the pathogenic fungi, more complex nutrient requirements than sugars are present; for example, Boocallis<sup>9</sup> found that, with *Helminthosporium sativum*, soil amended with potato broth gave 38–44 per cent germination, while dextrose broth gave only 0–1 per cent.

In conclusion, therefore, we would stress the necessity for distinguishing the type of inhibition being investigated, and the nutrient requirements of the test fungi used, in any further studies of this phenomenon of soil mycoestasis.

## STRUCTURE-FUNCTION RELATIONSHIPS IN THE ACTIVE C-TERMINAL TETRAPEPTIDE SEQUENCE OF GASTRIN

By DR J. S. MORLEY

Imperial Chemical Industries, Ltd., Pharmaceuticals Division, Alderley Park, Cheshire

AND

DR. HILDA J. TRACY and PROF. R. A. GREGORY, F.R.S.

Physiological Laboratory, University of Liverpool

THE heptadecapeptide amides gastrin I and II isolated from hog antral mucosa by Gregory and Tracy<sup>1</sup> are believed to be related to the hormone which is released from the antral mucosa during digestion and plays a major part in the stimulation of gastric secretion. The total synthesis of these peptides was accomplished by Anderson *et al.*<sup>2</sup>, following elucidation of their structures by Gregory *et al.*<sup>3</sup>. In an associated investigation, Tracy and Gregory<sup>4</sup> described the physiological properties of a series of synthetic peptides structurally related to gastrin I and showed that, of the 17 residues of the molecule, only the C-terminal tetrapeptide sequence Try-Met-Asp-Phe-NH<sub>2</sub> (which is found in both gastrins) is required for the remarkable range of physiological effects displayed by the natural hormones on the gastric and pancreatic gland-cells and on the gastro-intestinal musculature. They remarked that the simplicity of this active tetrapeptide and its wide range of distinctive actions make it a promi-

ing subject for the investigation of structure-function relationships by synthesis of analogues and exploration of their properties.

This article describes the results of such an investigation, in which 33 peptide derivatives have been synthesized and examined. Of these, 24 were analogues of the tetrapeptide in which a single substitution had been made in one of the amino-acid residues, or in the amide-group masking the C-terminal residue; in a further 4, more than one substitution was made. Two pentapeptide derivatives were also studied; one of these, *N*-*t*-butyloxycarbonyl-β-Ala-Try-Met-Asp-Phe-NH<sub>2</sub> (this and other active peptide derivatives are covered by pending patent applications in the name of Imperial Chemical Industries, Ltd.), proved to be particularly active. There were also examined: (1) the *i*-butyloxycarbonyl-tetrapeptide amide, BOC-Try-Met-Asp-Phe-NH<sub>2</sub>, which was comparable to the benzyloxycarbonyl-tetrapeptide amide in activity,

and the carbamoyl-tetrapeptide amide,  $H_2N.CO.Try.Met.Asp.Phe.NH_2$ , which was considerably more active; and (2) the *t*-butyloxycarbonyl tetrapeptide,  $BOC.Try.Met.Asp.Phe.OH$ , where the terminal amide group had been replaced by hydroxyl. Like related esters<sup>4</sup>, the latter was found to be almost inactive.

The two methods previously used in the synthesis of the C-terminal gastrin tetrapeptide amide by Anderson *et al.*<sup>3</sup> and the three additional methods (3-5) were suitably adapted in the synthesis of analogues. L- or D-Amino-acids of established purity were used in the preparation of all analogues except compounds 4-6, where DL-methyl-tryptophans were used (in method 3). Compounds 4-6 are therefore mixtures of the D-L-L-L- and L-L-L-L isomers. Compound 24 was prepared by methods 3 and 5 using aspartylphenylalanine in place of aspartylphenylalanine amide, and by saponification of  $BOC.Try.Met.Asp.Phe.OMe$ . The sulphone (compound 11) was also prepared by direct oxidation. The pentapeptide derivatives were prepared from the tetrapeptide amide by coupling with the appropriate active ester (compounds 29, 31), or by coupling with *N*<sup>α</sup>-benzyloxycarbonyl-*N*<sup>ε</sup>-*t*-butyloxycarbonyl-L-lysine 2,4,5-trichlorophenyl ester followed by hydrolysis of the product (compound 30). Compound 29 was also prepared by coupling *N*-*t*-butyloxycarbonyl-β-alanyl-L-tryptophan azide with L-methionyl-L-aspartyl-L-phenylalanine amide, and by coupling *N*-*t*-butyloxycarbonyl-β-alanyl-L-tryptophyl-L-methionine azide with L-aspartyl-L-phenylalanine amide. Compound 32 was prepared by direct carbamoylation of the tetrapeptide amide. The purity of all samples used for biological testing was established by thin-layer or paper chromatography in at least three different solvent systems, and, in some cases, by amino-acid analysis after acid or enzymatic hydrolysis, ultra-violet and p.m.r. spectroscopy and thin-layer or paper electrophoresis (after treatment of *BOC*-derivatives with cold trifluoroacetic acid). In cases where analogues were prepared by more than one method, the resulting samples had identical optical rotations; the rotations of compounds 3 and 27 and of 25 and 33 were equal and opposite to sign. In the synthetic work, details of which will be published elsewhere, we wish to acknowledge the valuable co-operation of Drs. H. Gregory, A. H. Laird and J. M. Smith.

BOC, Me<sub>3</sub>C.O.O.; Z, PhCH<sub>2</sub>; O, OCH<sub>2</sub>Ph; OCP, OC<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub> (2,4,5).

The actions of the natural gastrins and the experimental conditions in which they may be demonstrated have been described in detail by Gregory and Tracy<sup>1</sup>; the virtually identical properties of the C-terminal tetrapeptide amide, which is the parent compound of the present series of analogues, have been described by Tracy and Gregory<sup>4</sup>. Briefly, in conscious dogs provided with denervated pouches of the gastric fundus and/or isolated jejunal

loops, and in conscious or anaesthetized dogs arranged for the collection of pancreatic juice, the following effects are obtained: (1) Subcutaneous injections in appropriate dosage strongly stimulate gastric acid, but not pepsin, secretion; larger doses inhibit gastric acid secretion and stimulate pepsin secretion. (2) Rapid intravenous injections inhibit a 'background' secretory response maintained by continuous administration of histamine or of gastrin (I or II) and stimulate pepsin secretion; they also stimulate pancreatic secretion (volume-rate and enzyme secretion) and gastric tone and motility. They cause a biphasic intestinal response in which strong contraction is rapidly followed by inhibition of tone and motility. The C-terminal tetrapeptide amide has a small inhibitory action on basal gastric tone and motility following stimulation; this effect is not commonly seen with gastrin itself.

In the work recorded here, the same methods and the same group of surgically prepared animals were used as in the two previous investigations; the responses of these dogs to the gastrins and to the tetrapeptide were thus well established. As before, histamine was used as the stimulus for producing a steady 'background' secretion of gastric juice, against which to examine the power of each compound to: (1) inhibit gastric acid secretion; (2) stimulate pepsin secretion. In a few instances gastrin was used as the stimulus. In acute experiments in which pancreatic secretion was studied, the possibility (not previously explored) that gastrin or the peptides might act by liberating the intestinal hormones secretin and pancreozymin was excluded by removal of the entire small intestine.

For each peptide there were nine possible actions to be examined; and for a combination of reasons, formal assays of potency in respect of each were not feasible. It was therefore decided to express the findings in a simple manner based on the dosage level required for an effective response. This minimized the number of experiments required for each compound and made it possible to study a wide range of analogues, embracing several substitutions for each of the residues. The experimental procedure adopted was to test each compound first in a dose (50 μg) which was known to give a well-defined response in respect of all the possible actions when the 'parent' tetrapeptide was used. If comparable responses were observed with the analogue, this was indicated (Table 1) as +. If little or no effect was observed, larger doses were used on subsequent occasions, up to a maximum dose of 500 μg. Well-defined responses obtained at this dosage or small responses observed at a lower dose-level (200 μg) were marked as (+). Failure to respond to 500 μg was marked as 0; a doubtful positive response at this dose-level was indicated as (? +). As in the previous investigation<sup>4</sup> a few instances were found in which even maximal doses (500 μg) augmented, instead of inhibiting, a background histamine response when injected intravenously; as before, these were recorded as 0\*. The probable interpretation of this type of result is indicated by our finding that a very small (1 μg) intravenous injection of gastrin I or II augments a background histamine response; a larger dose (5 μg or more) causes the usual inhibition.

These are set out in Table 1, in which the peptides are arranged in five groups. The first four groups correspond to substitutions in the four residues of the parent tetrapeptide amide, and the final group is a miscellaneous group containing analogues with more than one substitution and *N*-acylated derivatives of the intact tetrapeptide amide. While, in general, the power to stimulate gastric acid secretion in a peptide derivative was associated with all the other types of activities enumerated for gastrins I and II, this was not always so. Thus, several peptides possessing the power to stimulate gastric acid secretion did not uniformly affect gastrointestinal motility (gastric motility in particular) (for example, compounds 9, 11, 12-15, 20, 21). Some that stimulated gastric secretion at high dosage did not inhibit at this level (for example, compounds 2, 3, 11, 12, 21) and there was an occasional

indication that inhibitory activity could be associated with lack of, or weak, stimulating properties (compounds 13 and 18). There were no cases of marked selectivity, in a qualitative sense, in respect of any of the properties studied. The power to stimulate the secretion of pepsin was more widely observed than any of the other physiological actions.

Restricting the discussion to the power to stimulate gastric acid secretion as seen in the gastrin C-terminal tetrapeptide amide, Try.Met.Asp.Phe-NH<sub>2</sub>, the following tentative conclusions may be drawn:

(1) Activity is preserved in all *N*-acylated derivatives of the tetrapeptide amide (compounds 29-33). The level of activity may vary considerably, but when the acylating group is *t*-butyloxycarbonyl- $\beta$ -alanyl or carbamoyl, the resulting peptide derivatives (compounds 29 and 32) show the same order of activity as gastrin on a simple weight-for-weight basis (Fig. 1). This situation parallels that reported<sup>4</sup> for  $\alpha$ -MSH; derivatives of  $\alpha$ -MSH in which the *N*-terminus is acylated may equal or exceed the biological activity of counterparts possessing a free *N*-terminal amino group.

(2) Substitution of all, or part, of the L-amino-acid residues by D-amino-acid residues leads to virtually complete loss of activity (compounds 10, 18, 25, 26, 27). There are two exceptions to this generalization:

(a) In compound 3, where L-tryptophan is replaced by D-tryptophan, some activity (chiefly on gland-cells) is shown at a high dosage level. This result is regarded as real, since there are clear indications that the geometry at this position is not critical (cf. high activity of compound 7). However, the possibility of activity being due, at least in part, to the presence of a small amount of the

L-L-L-L peptide cannot entirely be discounted; 1 per cent contamination would probably account for the activity shown. (b) Compound 22, where L-phenylalanine is replaced by D-phenylalanine, shows similar activity, particularly in respect of gastrointestinal motility.

Those compounds in which one or more D-amino-acids had been substituted for the L-forms were tested for their power to inhibit secretion when injected intravenously against a background response maintained by gastrin. The results did not differ significantly from those set out in column 2 of Table 1, which were obtained using histamine as the stimulus.

The general situation in regard to the D-form substitutions closely parallels that described for bradykinin by Stewart and Woolley<sup>6</sup> and contrasts with that described for the 6-10 MSH pentapeptide, His.Phe.Arg.Try.Gly, by Hano, Koida, Kubo and Yajima<sup>7</sup>. All D-bradykinin does not show bradykinin-like activity and does not inhibit the response to bradykinin, while inversion of a single amino-acid residue may preserve bradykinin-like activity. The all D-MSH pentapeptide is believed to be a competitive inhibitor of the physiological actions of the all L-pentapeptide and of MSH.

(3) Replacement of the tryptophan by other L-amino-acid residues (compounds 1 and 2) generally lowers activity considerably. However, activity may be preserved despite removal of the amino-group (compound 7), a result to be compared with the high biological activity of 'deamino-oxytocin'; and substitution of the tryptophan nucleus (compounds 4, 5 and 6) may produce highly active compounds (Fig. 1). This, to our knowledge, is the first recorded example of the biological effects of substitution in the tryptophan nucleus of a biologically active peptide,

Fig. 1. Secretory responses of a conscious dog provided with a denervated fundus pouch to the subcutaneous injection (on different occasions) of 10 µg of peptides 4, 5, 6, 7, 30, 32, 33 and gastrin II. Injection in each case at time 0. Ordinates, acid output per 15-min period (m equiv. total HCl) abscissae, time (h). The total acid output in each experiment is recorded.

although substituted tryptophan residues are probably present in the rufomycin group of antibiotics<sup>1</sup>.

(4) The methionine position will tolerate the greatest amount of change. Thus, the norleucine (compound 8) and ethionine (compound 9) analogues show high activity, and low activity is still found in the norvaline,  $\alpha$ -amino-butyric acid and alanine analogues (compounds 13, 14 and 15). The sulphone and *S*-oxide (compounds 11 and 12) are only marginally active.

The situation at the methionine position is closely paralleled by the results obtained by analogous replacements of methionine in ACTH<sup>10</sup> and  $\beta$ -MSH<sup>11</sup>.

(5) All changes at the aspartic acid position lead to virtually inactive compounds. Thus, the  $\beta$ -aspartyl and glutamic acid analogues (compounds 16 and 17) show only slight effects; while compound 19, where the polarity has been preserved while switching the terminal amide and aspartic hydroxyl groups, is the least active of any in this group, or indeed of any in the series except for the multi-D analogues 25–27. It is even less active than the free acid of the parent tetrapeptide, No. 24.

(6) At the phenylalanine position, the tyrosine analogue (compound 20) is only weakly active, but the *O*-methyl-tyrosine analogue (compound 23) has considerable activity. The former result recalls the considerable loss of activity that accompanies the replacement of phenylalanine by tyrosine in eliodoin<sup>12</sup>. Replacement of tyrosine by phenylalanine in oxytocin or in lysine vasopressin likewise lowers biological activity, but *O*-methyloxycytocin is either virtually inactive<sup>13</sup> or an antagonist of oxytocin<sup>14</sup>.

(7) Substitution of the terminal amide group by a cyclohexyl group (compound 21) greatly reduces the activity (dimethylation of the terminal amide group of eliodoin has a similar effect<sup>15</sup>), and the corresponding acid (compound 24) is almost inactive. This latter result confirms the observations on the methyl ester of the same compound made by Tracy and Gregory<sup>4</sup>; it was considered desirable to substantiate their findings by an independent synthesis and re-examination.

The interpretation of the fundamental importance of these structural changes in relation to physiological activity requires caution. First, many factors may influence the apparent biological activity seen in assays with intact animals. Secondly, there are many cases in the present investigation where a structural modification has resulted in a marked decrease of potency but not total inactivation. As Hofmann has pointed out<sup>6</sup>, an analogue exhibiting low activity still appears to retain the structural prerequisites for function although higher concentrations are required to achieve the biological effect. However, the results now obtained suggest that in the tetrapeptide amide sequence, and presumably also in gastrin, the tryptophan, methionine and phenylalanine positions are binding, rather than functionally active sites, and also that the most important feature of the molecules is the aspartic carboxylic-terminal amide relationship.

## EFFECTS OF RED AND BLUE LIGHT ON THE GROWTH AND MORPHOGENESIS OF *Acetabularia crenulata*

By DR. JOHN TERBORGH

Tyco Laboratories, Inc., Waltham, Massachusetts

**P**HOTOMORPHOGENIC responses are of great importance in the development of higher plants and have recently received much attention<sup>1</sup>. The only such response known for an alga, however, is that described by Lazaroff and Schiff for the blue-green alga, *Nostoc muscorum*<sup>2</sup>. Aseriate colonies growing in the dark on a medium containing sugar failed to differentiate unless exposed to weak illumination. Red light at 650 m $\mu$  was most effective in promoting the transition, and its effect was reversed by subsequent irradiation with wave-lengths between 500 and 600 m $\mu$ , but not by far-red. The findings of Haupt<sup>3</sup> and Haupt and Thiele<sup>4</sup>, respectively, that chloroplast orientation in the green alga *Mougeotia* and *Meoetacnium* is reversibly responsive to red and far-red light open the question of phytochrome-mediated reactions in algae. Moreover, the occurrence of photoperiodic responses in *Acetabularia* seems clear for vegetative growth, though not yet demonstrated as a direct effect for morphogenesis<sup>5</sup>.

One useful approach to the study of photomorphogenic reactions has been to explore the effects of exposing plants to light of limited spectral regions. Investigations of this kind have been carried out with several types of algae, but most of the recent work has been done with species having no clear-cut differentiation, such as *Ohlreella*. The siphonaceous green alga, *Acetabularia*, is remarkable for its large size and possession of a single nucleus which can easily be excised, leaving a nucleate and an enucleate fragment. The fact that both fragments are capable of regeneration, the former being totipotent and the latter being capable of enlargement by as much as 30–40 per cent and differentiation of a gametangium (cap), has made this organism a favourite subject for studies of nucleio-cytoplasmic relations<sup>6</sup>. The cell germinates from a zygote and grows out as a thin filament for several months until reaching a length of 20–30 mm, whereon elongation ceases and a disk-like cap forms at the apex of the stalk. This clear-cut two-stage development makes *Acetabularia* particularly well suited for studying morphogenic responses.

Investigations on the effects of light quality on *Acetabularia* have recently been undertaken independently in three laboratories. Richter<sup>7</sup> allowed 10-mm nucleate parts of *A. mediterranea* and *crenulata* to regenerate under broad-band red (570 m $\mu$  and upwards), and blue (400–600 m $\mu$ ) light sources adjusted to equal energy. In 3 months under these conditions both species had produced more than 20 mm of stalk, but those in red formed no caps while 78–94 per cent of those in blue did so. Plants of both species quickly initiated caps on being transferred to white light after 35 days in red light. Clausen, using Philips red and blue fluorescent tube sources, adjusted to equal energy, with the red passed through a 'Plexiglas' filter, obtained somewhat different results<sup>8</sup>. Nucleate parts of *A. mediterranea*, allowed to regenerate in continuous red illumination, grew less than 5 mm in 14 days and then ceased to grow entirely, but those given blue light grew at a steady rate and formed caps normally. The cells the development of which had been arrested in red light were able to resume growth and form caps when the red light régime was interrupted by 1 h or even 1 min of blue light. Far-red light was ineffective in replacing blue

light for this effect. 1 h of blue light per day in the absence of red light, however, was inadequate to support growth. In contrast to the results of Kowallik<sup>9</sup>, with synchronized cultures of *Ohlreella*, there was no differential effect of red and blue light on the protein/dry weight ratio of *Acetabularia*.

In the experiments reported here, cells or cell fragments of *A. crenulata* were exposed to various light régimes in 500-ml. Erlenmeyer flasks containing Erdschreiber medium. Control experiments used white light of several intensities from GE 'Daylight' fluorescent tubes. The blue source was a pair of 15-watt GE 'Blue' fluorescent tubes, in front of which was placed a dark blue 'Plexiglas' filter which did not transmit more than 580 m $\mu$  and gave peak transmission at 440 m $\mu$ . The red source in most of the experiments consisted of 2 or 4 15-watt GE 'Red' tubes, used with or without a Du Pont cellulose filter which had no discernible effect. This source provided a symmetrical band of radiation including wave-lengths from 590 to 720 m $\mu$  and had peak output at 640 m $\mu$ . The blue and red sources gave intensities of 1.5 and 1.6 m-watts/cm<sup>2</sup>, respectively. In one experiment tungsten bulbs were used with three thicknesses of red 'Cellophane' to provide a red source which did not transmit below 590 m $\mu$ , but was rich in wave-lengths more than 700 m $\mu$ .

Given continuous blue light, *A. crenulata* grew slightly more rapidly than when given a somewhat lower (1.2 mW/cm<sup>2</sup>) irradiance of white light (Fig. 1). The average rate of elongation of a culture was nearly linear until cap formation began; thereafter the growth registered was contributed only by those cells which had not yet initiated caps. The same pattern was observed with large capless cells (initial length 28.4 mm), and with cells initially of this size that had been cut back to 3.0 mm and allowed to regenerate. On the other hand, practically no growth occurred in red light; the large cells grew only

Fig. 1. Elongation of *A. crenulata* cells in white (W), blue (B) and red (R) light at 25–27° C. Sources were GE 'Daylight', 'Blue' (used with a filter which did not transmit above 580 m $\mu$ ) and 'Red' fluorescent tubes and gave energy fluxes of 1.2, 1.5 and 1.6 mW/cm<sup>2</sup>, respectively. ●—●, Intact cells, initially 28.4 mm in length. ●---●, cells of the same initial size but cut back to 3 mm and allowed to regenerate. Numbers over the terminal points refer to the percentage of cap-bearing cells in the sample at the end of the run.

0.9 mm in 13 days, while the regenerating cells grew 2.1 mm in the first 9 days but only another 5.3 mm in the following 182 days.

These and other similar experiments confirm Clause's result that growth virtually ceases in red light within two weeks. In an experiment similar to the foregoing but with the red source not carefully shielded from extraneous light, rapid growth in red light suggests that his somewhat broader source included wave-lengths that overcame the red effect, or that his cultures were occasionally exposed to white or blue light, possibly during measurements.

In comparison with white light that gave an approximately equal growth rate, blue light resulted in both quantitative and qualitative morphogenic effects. Cap formation was greatly delayed by blue light (Table 1). The time required for 50 per cent of the cells in a sample to initiate caps was much longer and the mean length of the cells in the sample at this time was considerably greater in blue light. These differences were particularly pronounced in the cells that regenerated from 3 mm bases in blue light (Fig. 2) in that they reached more than 2.5 times the length of the white light controls before forming caps. Another difference resulting from these treatments is revealed in comparing the effects of stalk amputation. It was shown by Beth that cells regenerating in white light after amputation produce caps at much shorter lengths than do intact cells<sup>10</sup>. This was clearly demonstrated in the present experiment (Table 1), where the respective lengths were 17 and 30 mm. However, the relationship was reversed in blue light, in which the generating cells, at the time of 50 per cent cap formation, were 6 mm longer on the average than the unoperated cells. Thus, the large cells that, as shown by the white light control, were on the verge of cap formation at the outset of the experiment were not delayed by blue nearly so much as those which had to regenerate.

This result implies that the (red component of) white light had had a preliminary morphogenetic effect on the intact cells before their transfer to blue light and that this effect was removed by amputation of most of the stalk.

Material	Light	Intensity of radiation (mW/cm <sup>2</sup> )	Time to 50% cap formation (days)	Mean cell length at 50% cap formation (mm)
Large cells	White	1.2	6	30
28.4 mm initially	Blue	1.5	19	37
Regenerating from 3.0 mm	Red	1.6	—	—
	White	1.2	24	17
	Blue	1.5	45	43
	Red	1.6	(> 188)	—

In addition to these quantitative effects, blue light produced a qualitative difference in cap morphology. Under laboratory conditions, in white light of moderate to high intensity, *A. oreanulata* differentiates at lengths between 20 and 30 mm, forming caps the individual chambers of which are free and without any particular orientation (at right in Fig. 2). Caps formed in blue light, however, were planar structures in which each chamber was laterally attached to the adjacent chambers (Fig. 2,

Fig. 2 Mature cap-bearing *A. oreanulata* cells grown in blue light (1.5 mW/cm<sup>2</sup>, at left) and white light (1.2 mW/cm<sup>2</sup>, at right). Note differences in cell length and cap morphology.

Fig. 3. Elongation of *A. oreanulata* cells in white light of two intensities ( $W_R$ , 0.2 mW/cm<sup>2</sup>;  $W_L$ , 0.05 mW/cm<sup>2</sup>) and in blue ( $B$ , 1.5 mW/cm<sup>2</sup>) and in red light ( $R$ , 1.6 mW/cm<sup>2</sup>) in differing proportions, 24  $R$ , continuous red illumination; 23  $B$ , 1  $R$ , 23 h red plus 1 h blue illumination per day, etc. Numbers over the terminal points refer to the percentage of cap-bearing cells in the sample at the end of the run. Initial mean cell length was 10.5 mm.

left). *A. oreanulata* as found in Nature differs conspicuously from cells grown in the laboratory in white light but closely resembles those that develop in blue light. A sample of 50 cap-bearing *A. oreanulata* cells from Biscayne Bay, Florida (I am greatly indebted to Dr. Stanley Burg and Ellen Burg for collecting this material), had a mean length of 45.3 mm and without exception possessed completely planar caps with mutually attached chambers. The length can be compared with a mean length of 44.7 mm for cells which formed caps in blue light in these experiments. Since the portion of the spectrum which penetrates the sea most readily lies between 450 and 550 m $\mu$ , the energy reaching a depth of a few metres at 650 m $\mu$  being only 11 per cent of that at 500 m $\mu$  (ref. 11), it seems likely that most of the morphological differences between laboratory cultures and natural populations can be accounted for by the spectral quality of the light reaching the cells. This conclusion also suggests that the red part of the spectrum, though apparently not by itself able to support growth, promotes (hastens) the initiation of functional but atypical caps when given in addition to blue.

The interaction of red and blue light has been examined in two ways. In one experiment cells were given continuous red or blue, or 23 h of either plus 1 h of the other, each day (Fig. 3). Growth performance in these régimes was compared with that in white light of two intensities, 0.2 and 0.05 mW/cm<sup>2</sup>, corresponding to energy fluxes far less than those provided by either the red or blue source. Compared with continuous blue light, 1 h of red plus 23 h of blue produced no discernible difference in growth. Caps were formed at approximately the same time and cell length in both régimes, and considerably later than in the low-intensity white light. Though in white light the cell length at morphogenesis is inversely dependent on light intensity<sup>12</sup>, caps were formed later (that is, at a greater length) in blue of a higher intensity than the white control, thus showing conclusively that the delayed morphogenesis in blue light was not due merely to an effect of intensity.

One hour of blue light inserted into a continuous red régime, however, had a very pronounced effect, as Clause also discovered<sup>8</sup>. While continuous red gave virtually no growth after the first 14 days, the insertion of 1 h of blue (that is, 23R, 1B) gave an appreciable and steady rate, roughly equal to that produced by white light of 12 ft.-candles (the latter, however, providing only 3 per cent of the daily irradiance). In another experiment it was found that the 23R, 1B régime gave 2.5 times the growth in 11 days that in sum took place in two cultures receiving separately 24R and 1B. Since, furthermore, Clause found that even 1 min of blue per day could enhance growth in red light, there can be no doubt that the two wave-length bands are synergistic.

In order to determine whether red light exerts any real inhibitory effect, rather than merely being insufficient for either growth or morphogenesis, experiments were run under light sources having widely different proportions of red and blue radiation while providing approximately the same total energy flux. These were obtained by combining GE 'Blue', 'Daylight' and 'Red' fluorescent tubes in various proportions. Blue tubes were used with a filter which entirely excluded red light. The ratio of energies received at 650 and 450 m $\mu$  was computed from spectral energy distribution curves published by the General Electric Co. Cultures grown under sources with  $I_{650}/I_{450}$  ratios of 0.0, 0.7 and 1.5 were found to elongate at the same rate over a period of 3 weeks before cap formation. The mean cell length in these cultures at the time of 50 per cent cap formation, however, was 34.8, 26.5 and 24.5 mm respectively. Thus the greater the proportion of red light received, the shorter the length at which caps are formed. The results show clearly that red light *per se* is not inhibitory, either to growth or to cap initiation, and again suggest that it hastens the latter.

Fig. 4. Elongation of enucleate cells of *A. crinale* in blue (1.5 mW/cm<sup>2</sup>) and red (1.6 mW/cm<sup>2</sup>) light. Cells given red light were transferred to blue light after 11 days. Numbers over the points refer to the percentage of cap-bearing cells in the sample. —●—, Blue Illumination; ---●---, red Illumination.

The fact that two weeks or more may pass before growth ceases altogether in red light suggests the slow disappearance of a rate-limiting substance or reaction which can be restored, or maintained in part, by as little as 1 min of blue light per day. That the substance(s) limiting growth in red light is both stored and produced in the cytoplasm is indicated by the data in Fig. 4 from an experiment with enucleate cells. Though the total growth capacity of enucleate cells is far lower than that of intact cells (2.9 mm growth in 20 days in blue light, compared with 15–20 mm for controls) they are able to grow nearly as much in red light (1.2 mm in 16 days compared with results of 0.9, 2.0 and 2.1 mm for nucleate cells), implying that the substance or process limiting growth in red light is primarily localized in the cytoplasm. Moreover, when the enucleate cells were placed in blue light after 16 days in red light the immediately resumed growth and formed caps, showing

that blue light can stimulate growth in the absence of a nucleus. The failure of *Acetabularia* to form caps in red light cannot be considered a specific inhibitory effect on morphogenesis, since growth is greatly restricted under these conditions. Cells placed in white light of an intensity low enough to limit growth likewise failed to initiate caps (see Fig. 3).

All attempts to relate the effect of red light on *Acetabularia* to previously described phenomena have so far been unsuccessful. Haupt's discovery of a reversible red, far-red effect on chloroplast orientation in *Mougeotia*<sup>9</sup> and *Mesostemonium*<sup>10</sup> implies that phytochrome may be of widespread occurrence among the algae. However, in our experiments red light alternating with dark periods of various lengths, or with dark periods broken by 5-min periods of far-red light, has produced no more growth than continuous red light. A red source made up with tungsten flood lamps and red filters was richer in far-red light than in red and should have brought the two forms of phytochrome to a steady-state equilibrium, but this also failed to promote growth.

The possibility that Emerson enhancement of photosynthesis is involved seems excluded in view of the facts that (a) the red sources used in these experiments contained wave-lengths down to 590 m $\mu$ , and (b) several experiments with interference filters showed that photosynthesis in *A. crinale* was considerably more efficient at both 684 and 694 m $\mu$  than at 450 m $\mu$ . Furthermore, a direct short-wave-length enhancement of photosynthesis is in any case improbable because irradiation by the two wave-length regions need not be simultaneous in order to be effective.

Nitrate reduction is known to be stimulated by the blue end of the spectrum. However, replacing the NO<sub>3</sub><sup>-</sup> by ammonium salts in the normal Erdschreiber medium, or adding various amino-acids, had no stimulatory effect on growth in red light.

Red and blue light have been found to have differential effects on many plant systems; in higher plants on catalase activity<sup>12</sup>, protein and carbohydrate contents<sup>13,14</sup> and oxygen uptake<sup>15</sup>. Various green algae, red algae and diatoms have been grown under broad-band red, green and blue light sources with resulting growth rates that can be largely explained in terms of the relative intensities of the sources and/or the absorption characteristics of the species in question<sup>16,17</sup>. In no case did light which was absorbed to an appreciable extent fail to support development, although, interestingly, the diatom, *Chaetoceros*, assumed a larger average cell size in blue light than it did in red<sup>18</sup>. Kowalik, working with cultures of *Chlorella* synchronized by an alternating light-dark régime in which the light supplied was either red or blue, found differential effects of light quality on the time of division, the average size, RNA content, and protein/carbohydrate ratio of the cells in these cultures<sup>19</sup>. The photochemical mechanism responsible for these differences is still obscure, though they may possibly be related to the results with *Chlorella* of O'Leary and Emerson<sup>20</sup> and Hauschild *et al.*<sup>21</sup>, who found, using <sup>14</sup>CO<sub>2</sub> in short-term experiments, that blue light stimulated a greater incorporation of label into several amino-acids than did red light. That red light might alter the products of photosynthesis in *Acetabularia* in such a way as to halt growth remains as a possible explanation of its effect, even though several attempts to enhance the growth of *A. crinale* cells in red light by supplementing the normal inorganic medium with sugars, acetate or amino-acids were unsuccessful. The fact that small quantities of blue light can catalyse growth and even cap formation in red light suggests that blue light may stimulate a specific non-photosynthetic process or the photoconversion of a reserve substance stored in the cytoplasm.

## METHOD FOR CHARACTERIZING SAWFLY EGG PIGMENTATION

By D. R. WALLACE

Forest Insect Laboratory, Sault Ste. Marie, Ontario

AND

I. M. CAMPBELL

Iowa State University, Ames, Iowa

DURING the course of genetic investigations it was noted that, in some families of *Neodiprion swainsoni* Middleton, sister females had either green or yellow abdominal venters, resulting from similar colour differences in the contained egg masses. Observations on a number of common diprionid species showed wide inter-specific variation in the egg colour. Forsius<sup>1</sup> recorded a great variety of colours among the unlaid eggs of 124 species of European sawflies, and Scheidter<sup>2</sup> and Sturm<sup>3</sup> used the colour of laid eggs in field diagnoses of the egg clusters of central European diprionid species. In spite of these earlier observations on egg colour and the apparent usefulness of this characteristic, taxonomists and other workers have not undertaken detailed examinations of it. There are probably two main reasons for this lack of interest: taxonomists in the past seldom investigated living specimens or had such material readily available; secondly, meaningful colour descriptions were not easy to achieve. The latter problem became very evident to us in the early stages of the work. Initially, attempts were made to obtain ratings by comparisons with standard colour charts in the *Munsell Book of Color*<sup>4</sup>. Although much superior to arbitrary descriptions, this approach was of limited value because of its intrinsic subjectivity. A spectrophotometric method of assessment appeared feasible and also desirable. The opal glass transmission method of Shibata<sup>5</sup> was adapted for use with sawfly eggs in the following manner.

A full egg complement, removed from a naturally emerged female by cutting off the tip of the abdomen just anterior to the genitalia, was placed in a shallow, open-ended trough on an opal slide (Fig. 1). The opal slide consisted of a 50 × 12 mm rectangular piece cut from commercial opal glass about 3.4 mm thick, comprising a 0.4-mm opal layer bonded to a clear back about 3 mm thick. Two 20 × 2 mm pieces of No. 0 cover glass (0.085–0.13 mm thick) were cemented to the opal surface spaced about 3 mm apart, and in a position such that, when the opal slide was inserted vertically in the cuvette carrier, the beam passed through the centre of the 20 × 3 mm area between the rectangles of cover glass. The eggs were placed on the opal slide, covered with 0.15 M sodium chloride solution, and then separated from one another using fine forceps. Unwanted materials, such as ovariole tissue, immature eggs, and portions of the gut, were removed and the eggs washed with the saline, using filter paper to remove the wash solution. The eggs were arranged more or less in a single layer filling the beam

area of the trough. A slip of No. 0 cover glass was placed over the layer of eggs and saline was then run under the cover, filling the voids between eggs by capillary action. Excess saline was removed with a piece of filter paper to the extent that the cover glass was drawn tightly over the eggs, but the space under the cover around the eggs was completely filled. The edges of the cover were sealed with rubber cement, taking care to leave the beam area clear. Drying of the rubber cement tended to draw the cover slip even more tightly over the eggs, flattening them slightly and helping to lock them in position. A saline-filled reference slide was prepared in the same manner without eggs.

The sample and reference slides were placed in the cuvette carrier of a Beckman 'DU' spectrophotometer with photomultiplier so that the opal surfaces of the slides faced the monochromator. Hard cork blocks were used to ensure stability and uniform placement in the carrier. Optical density readings were taken at 10-mμ intervals, or at more closely spaced positions in regions of band maxima, over the range 360–700 mμ, using the tungsten source and a constant slit width of 0.78 mm. The beam size, normally about 6 mm high by 3 mm wide, with a slit of 0.78 mm, was reduced to less than 1 mm in diameter

Fig. 1. Arrangement of opal slide bearing sawfly eggs

by using a microcell slide adapter with its smallest aperture (0.46 mm) in position. High electrical gain was required in the near ultra-violet range and at the red end of the visible spectrum. Each run took about three-quarters of an hour with an instrument operator and a record taker.

Little difficulty was encountered in using the foregoing method and satisfactory egg spectra were obtained (Fig. 2). The length of time required to obtain a single spectrum and the lack of a continuous record over the test range, however, caused some difficulty. It was impossible to obtain spectra of a satisfactory number of egg complements during the fairly short period that adults of any given type were available. The long observation period was particularly troublesome while determining the stability of the preparations and when instrument instability was suspected. The repeated mechanical shifting of the sample-positioning carriage, necessary to place the reference and sample slides alternately in the beam, often caused changes in the spacing of eggs during the course of a run. In most instances such shifts were detected as sudden unexpected changes in optical density, but the danger of not noticing more subtle changes was always present, and frequent re-checking of the optical density at the starting wave-length was required. Beam restriction intensified the problem of shifting eggs and introduced a sampling effect, because only a few of the eggs produced by a female were in the beam, and there is some variation in egg colour within a single complement. Subsequent investigations showed that it is undesirable and unnecessary to reduce the beam area by masking. The high electrical gain required at the near ultra-violet and red ends of the spectrum prevented accurate readings and limited the spectral range amenable to examination. In addition, the large slit width resulted in poor resolution

as the spectral slit width was 11 m $\mu$  at 360 m $\mu$  and 78 m $\mu$  at 700 m $\mu$ . In later work, most of the difficulties associated with instrumentation were overcome by using a recording spectrophotometer.

Utilization of the complete egg complement obtained by dissection of individual females avoids the time-consuming and painstaking work required to dissect eggs from needles once they have been laid. Moreover, the use of eggs dissected from females enhances repeatability, since once oviposition takes place, embryogenesis commences even in those species overwintering in the egg stage<sup>4</sup>, and it is doubtful if meaningful spectra could be obtained without recourse to uniform sample timing. On the other hand, our observations suggest that the total egg production of a diprionine female is developed by the time of emergence from the cocoon, and Smith's<sup>5</sup> work on *Gilpinia hercyniae* (Hartig) indicates that at the time of emergence the eggs are relatively quiescent, all in a single stage of development, awaiting the stimulus of oviposition to trigger the maturation divisions of the nucleus. During our investigation, neither resorption of eggs over a prolonged adult life-span nor changes in egg pigmentation during the life-span of the adults after normal emergence from the cocoon have been observed, and the pigments were found to be stable in egg preparations over the period of spectrophotometric examination.

Because it was not possible to control the thickness of the egg preparations and the spaces between eggs to a fine degree, the spectra ranged from relatively flat ones of overall low apparent density to ones with very distinctive features and high apparent density. However, by plotting the spectra on a log<sub>10</sub> ordinate scale, a common practice in the investigation of characteristic spectral form<sup>6</sup>, curves of reasonably similar shape were obtained from preparations of very different thickness and spacing (Fig. 2). This technique allowed a visual analysis of spectral homogeneity among individuals of the same as well as different populations.

Fig. 2 illustrates a number of spectra of the blue-to-turquoise eggs of *Diprion simile* (Hartig), the yellow-green eggs of *Gilpinia hercyniae* (Hartig), the orange-yellow eggs of *Gilpinia fructorum* (Fabricius), the purple-brown eggs of *Neodiprion sertifer* (Geoffroy) (all Diprionidae: Diprioninae), the pale yellow eggs of *Pitonema alaskensis* (Rohwer), and the yellow-green eggs of *Pitonema dimmocki* (Cresson) (Tenthredinidae: Nematinae). Consistent differences in spectral form are evident, which is not surprising, since the egg colour differences in the examples chosen are all readily observed by eye, but the method works equally well even when slight or no colour differences are visually discernible.

An initial investigation of the chemical basis of egg pigmentation showed that moderate-to-strong yellow colours associated with absorption shoulders in the region about 450 m $\mu$  are due to carotenoids, and that the blue, green and purple colours correlated with absorption maxima at wave-lengths longer than 570 m $\mu$  are produced by bile chromoproteins.

The application of the foregoing method to problems in the taxonomy of the conifer sawflies (Hymenoptera: Diprionidae) was demonstrated at the Centennial of Entomology in Canada, September 1963 (ref. 9). A full account of this work and its subsequent development will be published elsewhere.

## CENTRIFUGAL FIBRES TO THE RETINA IN THE MONKEY AND CAT

By R. N. L. BROOKE, DR. J. de C. DOWNER and DR. T. P. S. POWELL

Department of Human Anatomy, University of Oxford, and Medical Research Council, Cerebral Functions Research Group, University College, London

IN normal material stained by the Golgi method, centrifugal fibres have been described in the retinae of birds and mammals<sup>1</sup>. Recently, experimental neurohistological evidence has been provided for the origin, course and termination of such fibres in the pigeon together with the details of the organization of the afferent connexions and projection of their nucleus of origin<sup>2</sup>. There is good evidence from electrophysiological experiments for the presence of such fibres in mammals<sup>3</sup>; but so far it has not been possible to demonstrate them unequivocally with axonal degeneration methods. It is now known that both normal and degenerating nerve endings in certain parts of the central nervous system cannot be stained by silver methods, but that it is possible to recognize them with the electron microscope<sup>4</sup>. For these reasons it was thought that degenerating centrifugal fibres might be seen in ultra-thin sections of the retinae of mammals with the electron microscope. In preliminary experiments the retinae of pigeons, in which the nucleus of origin of the centrifugal fibres had been destroyed, were examined with the electron microscope. After these experiments on the pigeon had shown that electron microscopical techniques can be used to demonstrate degenerating centrifugal fibres in the retina, similar investigations were made in two mammals.

In the pigeons large lesions were placed in the mid-brain, in monkeys the optic tract was divided, and in cats the optic nerve was cut at its junction with the optic chiasma. After survival periods varying from six to fourteen days the animals were anaesthetized, the eyes removed and their anterior halves and vitreous removed before fixation of the retinae with veronal-buffered osmic acid; the retinae of the monkeys and cats were cut vertically close to the optic disk into 'nasal' and 'temporal' halves, and each of these halves was in turn divided vertically into 'inner' and 'outer' halves. All four parts were then cut into small blocks approximately 1 mm<sup>3</sup> in size, and after dehydration and staining with phosphotungstic acid were embedded in 'Araldite'. The brains of all the animals were fixed in formalin, and sections were cut and stained with the method of Nauta<sup>5</sup> in order to determine the site and extent of the lesion.

In the pigeon, evidence of degeneration of fibres and terminals is found only in the retina of the eye on the side opposite to that of the lesion in the brain stem<sup>2</sup>. In the optic nerve fibre layer an occasional fibre, or group of two or three adjoining fibres, are distinctly abnormal in appearance. These altered fibres are larger than the normal optic nerve fibres, contain whorls of electron-dense 'membranes' and have numerous shrunken, opaque mitochondria (Fig. 1). Similar degenerating fibres are seen between the cell bodies of the ganglion cells and at all levels of the inner plexiform layer as far out as the inner aspect of the bipolar cell layer. Degenerating fibres and very dense presynaptic endings are found in relation to the cell bodies of the amacrine cells, a thin process of a Müller cell usually intervening. A degenerating fibre or terminal has been seen directly apposed to the membrane of an amacrine cell; but, because of the absence of localized membrane thickening, it has not been possible to identify with certainty a degenerating presynaptic ending making a direct axo-somatic synapse with an amacrine cell. In some instances, where a degenerating presynaptic ending is opposite the junction between two

very thin Müller cell processes, a thickening of the plasma membrane of the amacrine cell body is evident, suggesting the edge of an axo-somatic synapse. Close to an amacrine cell body degenerating fibres can be seen bifurcating into presynaptic terminals, the fibre and ending together having the shape of a Y. The number of degenerating axons and terminals is very small; sections of many blocks contain none, and not more than three fibres have so far been found on any particular section, even when there are several dozen normal fibres in the layer of optic nerve fibres. These observations on ultra-thin sections are thus in complete agreement with those made with conventional neurohistological methods regarding the number and distribution of the centrifugal fibres.

In the retinae of the eyes of monkeys seven days after section of the optic tract there is also evidence of degeneration of a small proportion of the fibres. In the optic nerve fibre layer the cross-sectional area of these degenerating fibres is several times greater than that of the normal fibres, and they contain numerous mitochondria. In some of these fibres the mitochondria are larger than normal, are clear and have no distinct cristae; in the majority, however, the mitochondria are dense and opaque, and are so numerous that they completely fill the axon (Fig. 2). In a few instances the degenerative process has proceeded further, to the stage seen in the pigeon, so that the normal appearance of the fibre is completely altered owing to the presence of whorls of dense 'membranes' or lamellae. Degenerating fibres, usually at more advanced stages of degeneration, can be seen throughout the inner plexiform layer and on the inner aspect of the bipolar cell layer. In the outer third of the inner plexiform layer very dense remnants of presynaptic endings have been found occasionally (Fig. 4); there is difficulty in identifying the membrane thickenings, however, and it is

Fig. 1. Degenerating centrifugal fibre in optic nerve layer of retina of pigeon 11 days after destruction of the nucleus of origin of the centrifugal fibres ( $\times 15,000$ )

not possible to be certain of the type of process with which they are related. In the areas of the inner plexiform layer in which degenerating axons and terminals are seen, and most frequently near the outer border of the inner plexiform layer, dense masses are found within the glial cytoplasm. The appearance of these masses is very similar to that described in the cerebral cortex by Colonnier and interpreted by him as phagocytosed presynaptic endings<sup>7</sup>. Because of the sampling difficulties inherent in electron microscopical techniques, any assessment of the number and distribution of the degenerating fibres must be considered to be only tentative, but, with this qualification, it may be stated that they are relatively few, and the observations made so far suggest that their number is of the same order of magnitude as in the pigeon,

Fig. 2. Degenerating centrifugal fibre in optic nerve layer of retina of monkey seven days after section of the optic tract ( $\times 15,000$ )

Fig. 3. Degenerating fibre in inner plexiform layer of retina of cat six days after cutting the optic nerve ( $\times 30,000$ )

Fig. 4. Degenerating endings near outer border of the inner plexiform layer. A and B of monkey ( $\times 40,000$ ), C of cat ( $\times 55,000$ )

where previous work has shown them to form 1 per cent of the total number of fibres in the optic nerve<sup>8</sup>. One to three degenerating fibres have been seen on sections of approximately half the twenty blocks of 'inner' retina which have been examined. They are most numerous on sections which can be identified as being from the perfoveal region, and in sections of one block of this region up to ten such degenerating fibres are seen in the optic nerve fibre layer. In sections from thirty blocks of the 'outer' retina, however, only an occasional degenerating fibre and terminal have been recognized.

Six days after section of the optic nerve in the cat similar, but less marked, changes are seen in a few fibres in the optic nerve fibre layer of the retina. The affected axons are larger than the normal optic nerve fibres, and are filled with numerous mitochondria; the latter are enlarged, pale, and have no distinct internal structure. In the inner plexiform layer occasional degenerating fibres and terminals are seen, and these show a more advanced degree of degeneration than those in the layer of optic nerve fibres. The axons (Fig. 3) contain many small, opaque masses, fused mitochondria, whorls of lamellae, and, in some instances, lamellae arranged in a regular concentric manner around altered mitochondria. The degenerating terminals are especially dense (Fig. 4), and it is not possible to be certain of their precise relationship to other processes. Glial phagocytosis of dense debris is also present.

These electron microscopical observations of the retina following lesions of the central visual pathway may be accepted as valid evidence for the presence of centrifugal fibres to the retina in the mammal for several reasons. The changes which have been observed in the fibres of the optic nerve fibre and inner plexiform layers are similar to those described in other sites in the central and peripheral nervous system<sup>1-3</sup>, and the findings in the monkey and cat are essentially the same as in the pigeon, where the observations made with the electron microscope confirm those obtained with conventional neuro-histological methods. The fact that the degenerating fibres are most numerous in the region of the fovea in the monkey is in agreement with the statement of Ogden and

Brown\* that the P wave, elicited on stimulation of the optic nerve and considered by them to be due to activation of centrifugal fibres, is found consistently only in this part of the retina. It might be argued that the changes which have been described in some of the axons of the optic nerve fibre layer might be indicative of retrograde fibre degeneration, but if this were so it would have been found in the majority of the fibres in this layer, instead of in so few. The degenerative process affects predominantly the mitochondria<sup>8</sup>, and at the survival periods used in this investigation no appreciable increase has been observed in the number of neurofilaments which are normally present in the axons of the optic nerve fibre layer, and there is no evidence of the formation of neurofilaments in the degenerating terminals. In view of the theory that the presence of neurofilaments is necessary for the impregnation of a nerve terminal by silver<sup>10</sup>, this observation might explain the failure to demonstrate such terminals with the paraffin method of Nauta (unpublished observations). The failure to find many degenerating terminals can probably be explained on the basis that the survival periods after operation were too long, as it has been found that, in the lateral geniculate nucleus of the cat, at seven days "fragments that can be clearly identified as former boutons have been difficult to detect by E.M."<sup>11</sup>.

Further work with shorter survival periods should give evidence of the precise synaptic relationship of the terminals of these centrifugal fibres. In addition, it will be of interest to determine, by the method of retrograde cell degeneration, the site of origin of these fibres and of

the relationship of this nucleus to the superior colliculus. In view of the well-organized projection of the optic tectum on the nucleus of origin of the centrifugal fibres in the avian brain it would be reasonable to expect a similar connexion in the mammal. The importance of such a projection from the superior colliculus to the cells of origin of the centrifugal fibres would be two-fold; first, it would serve as a link between the afferent (retina to colliculus) and efferent (centrifugal) limbs of a feedback mechanism acting on the intrinsic neurones of the retina; and secondly, because there is a substantial projection from the visual and other areas of the cerebral cortex<sup>12</sup> to the superior colliculus, there is the possibility of a cortical influence on the activity of the retina.

## PHOTOSYNTHETIC PHOSPHORYLATION AND ELECTRON TRANSPORT

By PROF. DANIEL I. ARNON, HARRY Y. TSUJIMOTO and BERAH D. MCSWAIN

Department of Cell Physiology, University of California, Berkeley

THE formation of adenosine triphosphate (ATP), the 'energy currency' of living cells, occurs at the expense of free energy liberated during electron transport. The early type of ATP formation in photosynthesis<sup>1-3</sup>, now known as cyclic photophosphorylation, yields solely ATP and produces no net change in any external electron donor or acceptor. Here the coupling between ATP formation and active electron transport could only be inferred as being of a closed or cyclic type that is hidden in the structure of the chloroplast<sup>4,5</sup>. Direct experimental evidence of a coupling between the light-induced synthesis of ATP and electron transport came from non-cyclic photophosphorylation—a type of photosynthetic phosphorylation in chloroplasts in which ATP formation is stoichiometrically coupled with a light-driven transfer of electrons from water to a terminal electron acceptor and the resultant evolution of oxygen<sup>6</sup>. Both cyclic and non-cyclic photophosphorylation quench chloroplast fluorescence—a recent finding which is consistent with their role as the early energy conversion processes in photosynthesis<sup>7</sup>.

Since cyclic and non-cyclic photophosphorylation generate the assimilatory power in photosynthesis, their mechanisms and interactions are of considerable interest. Previous work led to two hypotheses: (a) cyclic and non-cyclic phosphorylation have a common site for ATP formation<sup>4,5</sup>; (b) non-cyclic photophosphorylation requires the collaboration of two light reactions (connected by a chemical 'bridge' of dark reactions) to bring about the transfer of one electron from water to a terminal electron acceptor<sup>8-10</sup>.

The purpose of this article is to present and discuss new evidence which leads us to abandon both these hypotheses and to re-interpret our earlier findings. We

now conclude, first, that cyclic and non-cyclic photophosphorylation in chloroplasts involve different pathways of electron transfer and do not have a common site for ATP formation. Our second hypothesis is that non-cyclic photophosphorylation involves not two but only one light reaction. According to this hypothesis only one quantum of light is required to transfer one electron from water to the terminal electron acceptor and to produce simultaneously the equivalent amount of ATP and oxygen. The new hypothesis that cyclic and non-cyclic photophosphorylation are bound to distinct electron transport pathways parallels the two modes of ATP formation in non-photosynthetic cells: (a) by substrate level phosphorylation in the course of fermentation; (b) by oxidative phosphorylation during respiration.

**Ferredoxin and photophosphorylation.** Before dealing with the present data, it is necessary to consider briefly recent evidence on the role of ferredoxin in cyclic and non-cyclic photophosphorylation. In non-cyclic photophosphorylation ATP formation was originally thought<sup>4</sup> to be linked with what appeared to be a photoreduction of nicotinamide adenine dinucleotide phosphate<sup>8</sup> (NADP) or an artificial substitute (for example, ferricyanide). But recent evidence has established that illuminated chloroplasts (grana) do not react directly with NADP<sup>11</sup>. The substance which is photoreduced by chloroplasts is not NADP but the water-soluble, iron protein, native to chloroplasts, now called ferredoxin (for the basis of this nomenclature see ref. 11). NADP reduction proper is separated by two dark reactions from the photochemical reduction of ferredoxin: (a) the re-oxidation of reduced ferredoxin by a flavoprotein chloroplast enzyme, ferredoxin-NADP reductase; (b) the re-oxidation of the reduced ferredoxin-NADP reductase by NADP<sup>11</sup>.

Ferredoxin was identified as the crucial, physiological electron acceptor in non-cyclic photophosphorylation<sup>10</sup>. The oxidation-reduction of ferredoxin was found to involve the transfer of one electron<sup>11,12</sup>. This was confirmed by the stoichiometry of non-cyclic photophosphorylation in which the photo-reduction of 4 moles of ferredoxin was coupled with the formation of 2 moles of ATP and 1 mole of oxygen<sup>10</sup> (equation 1):

The left-hand side of equation (1) shows four moles of water to indicate that we envisage, in the reduction of ferredoxin, each molecule of water (OH<sup>-</sup> at pH 7) yielding only one electron.

In experiments with isolated chloroplasts it is usually more convenient to measure non-cyclic photophosphorylation by using catalytic amounts of ferredoxin and stoichiometric amounts of NADP which, unlike chloroplast ferredoxin, is commercially available and relatively stable to oxygen. However, this operational convenience must not obscure the nature of ferredoxin as the terminal electron acceptor in non-cyclic photophosphorylation and the strongest reductant<sup>14</sup> (about 100 mV more electro-negative than NADP) that has been isolated so far from the photosynthetic apparatus. In experiments with isolated chloroplasts, non-physiological electron acceptors (for example, ferricyanide, benzoquinone) can readily replace ferredoxin to give stoichiometric oxygen evolution (Hill reaction) and, often, a coupled photophosphorylation, but at a great loss in the generated reducing potential.

The role of ferredoxin is not confined to non-cyclic photophosphorylation. Under strictly anaerobic conditions, when the photoproduction of oxygen by chloroplasts is suppressed, ferredoxin also catalyses cyclic photophosphorylation<sup>15</sup> (equation 2):

A characteristic feature of ferredoxin-catalysed cyclic photophosphorylation—not seen when other catalysts are used—is its sensitivity to low concentrations of two inhibitors, antimycin A and 2,4-dinitrophenol<sup>16</sup>. Both these inhibitors are noted for their inhibition of oxidative phosphorylation; hence the likelihood that portions of the enzymatic apparatus of oxidative and photosynthetic phosphorylation are similar. In oxidative phosphorylation inhibition by antimycin is considered to be indicative of the participation of cytochrome *b* in electron transport. It is possible, therefore, that cytochrome *b*, of chloroplasts participates in the ferredoxin-catalysed cyclic photophosphorylation and accounts for its sensitivity to antimycin A. There is no evidence that cytochrome *b*, is involved in the cyclic photophosphorylation catalysed by such exogenous catalysts as phenazine methosulphate.

Another feature of ferredoxin-catalysed cyclic photophosphorylation is consistent with its being the physiological type. Under very low light intensity, ferredoxin is much more effective than other co-factors of cyclic photophosphorylation in catalysing the conversion of radiant energy to the pyrophosphate bond energy of ATP (Fig. 11, ref. 16).

**Desaspidin and ferredoxin-dependent photophosphorylation.** Baltscheffsky and de Kiewiet<sup>17</sup> introduced to the study of photosynthetic phosphorylation a new inhibitor, a phlorobutyrophenone derivative, desaspidin, used in medicine as an anthelmintic agent and found by Runeberg<sup>18</sup> to act as a powerful uncoupler of oxidative phosphorylation. The remarkable property of desaspidin is that at very low concentrations (about 10<sup>-7</sup> M) it inhibited cyclic photophosphorylation catalysed by phenazine methosulphate, menadiene and dichlorophenol indophenol, whereas a similar degree of inhibition of non-cyclic photophosphorylation required desaspidin at about a 100 times

Fig. 1. Effect of desaspidin on ferredoxin-catalysed cyclic and non-cyclic photophosphorylation. In both systems, the reaction mixture (final volume 1.5 ml.) included spinach chloroplasts (equivalent to 250 µg of chlorophyll) and the following in µmoles: Tris buffer, pH 8.0, 50; MgCl<sub>2</sub>, 2.5; ADP, 5; and K<sub>2</sub>HPO<sub>4</sub>, 5. In the non-cyclic system, 0.2 mg ferredoxin and 5 µmoles NADP were also added. In the cyclic system, 8 mg ferredoxin and 2 µg (6.7 × 10<sup>-4</sup> M) of *p*-chlorophenyl-1,1-dimethyl urea (CMU) were added. Desaspidin was added as indicated. Temperature, 20°, illumination, 20,000 lux (yellow light) for 10 min, gas phase, argon. Other methods are given in ref. 10.

greater concentration<sup>17</sup>. In the experiments of Baltscheffsky and de Kiewiet<sup>17</sup> and Gromet-Elhanan and Arnon<sup>19</sup>, sensitivity to inhibition by low concentrations of desaspidin gave a new and unambiguous criterion by which cyclic photophosphorylation was distinguished from the non-cyclic phosphorylation that is associated with the transfer of electrons from OH<sup>-</sup> to NADP (via ferredoxin) or to such Hill reagents as ferricyanide.

In the present investigation, cyclic photophosphorylation catalysed by ferredoxin exhibited the same sensitivity to low concentrations of desaspidin as was observed with the non-physiological catalysts<sup>17,19</sup>. Fig. 1 shows that 5 × 10<sup>-7</sup> M to 10<sup>-6</sup> M desaspidin inhibited almost completely ferredoxin-catalysed cyclic photophosphorylation, but 5 × 10<sup>-6</sup> M to 5 × 10<sup>-5</sup> M desaspidin was required to inhibit non-cyclic photophosphorylation to the same degree.

An interesting effect of desaspidin was observed on ferredoxin-catalysed photophosphorylation in the presence of air. We have previously reported that this type of photophosphorylation is of the pseudocyclic type<sup>10,11</sup>, that is, a special case of non-cyclic photophosphorylation in which electrons are transferred from OH<sup>-</sup> to ferredoxin and thence to molecular oxygen. This non-cyclic electron flow from OH<sup>-</sup> to O<sub>2</sub> via ferredoxin gives the appearance of a cyclic electron flow since manometric measurements give no indication that an electron donor and acceptor are being consumed concomitantly with ATP formation. In pseudocyclic photophosphorylation the consumption of oxygen at the terminal end of the electronic pathway is balanced<sup>10</sup> by the production of oxygen at the site of electron donation by OH<sup>-</sup>.

Table 1 shows that, in the presence of air, ferredoxin-catalysed phosphorylation was 83 per cent inhibited by desaspidin (5 × 10<sup>-7</sup> M) at the lowest concentration of ferredoxin (0.2 mg/1.5 ml.), but ATP formation became progressively more resistant to desaspidin as the concentration of ferredoxin increased (7 per cent inhibition at 3.0 mg ferredoxin/1.5 ml.). Conversely, *p*-chlorophenyl-1,1-dimethyl urea (CMU), the well-known inhibitor of oxygen evolution and hence of pseudocyclic phosphorylation by chloroplasts, gave 11 per cent inhibition at the lowest concentration of ferredoxin and 65 per cent

Table 1. EFFECT OF DESASPIDIN ON FERREDOXIN-CATALYSED PHOSPHORYLATION IN AIR

Ferredoxin added (mg)	ATP formed (µmoles)		
	Control	Desaspidin	CMU
0.2	1.12	0.19	1.00
1.0	2.88	1.06	1.32
2.0	3.18	2.25	1.41
3.0	3.43	3.17	1.20

The experimental conditions were as given for Fig. 1, except that NADP and argon were omitted. The concentration of desaspidin was 5 × 10<sup>-7</sup> M and of CMU, 6.7 × 10<sup>-4</sup> M. Ferredoxin was added as indicated.

inhibition at the highest concentration of ferredoxin (Table 1).

These results indicate that, in the presence of air, ferredoxin catalysed a mixed type of photophosphorylation. At the lowest concentration of ferredoxin, the phosphorylation was predominantly of the cyclic type, whereas at the highest concentration of ferredoxin used, the phosphorylation was predominantly non-cyclic or, more specifically, its pseudocyclic variant.

**Non-cyclic photophosphorylation of the bacterial type.** Deaspidin proved to be especially useful in clarifying the nature of a phosphorylation in chloroplasts that is coupled with an artificial non-cyclic electron flow system, that is, a system in which  $\text{OH}^-$ , the natural electron donor for non-cyclic photophosphorylation in chloroplasts, is replaced by a reduced indophenol dye<sup>11</sup>. The background of this problem is as follows.

Losada *et al.*<sup>8</sup> found that this 'bacterial type' of non-cyclic electron flow in chloroplasts is coupled with a phosphorylation. It was classified as a 'bacterial type' because photosynthetic bacteria cannot use  $\text{OH}^-$  as an electron donor but exhibit a non-cyclic electron flow from other, less-oxidized, electron donors (for example, succinate) to pyridine nucleotide<sup>12,13</sup>. Losada *et al.*<sup>8</sup> also observed that photophosphorylation in chloroplasts occurred when oxygen evolution was suppressed and the dye was maintained in the reduced state by an excess of ascorbate. On the other hand, little phosphorylation occurred when the dye was maintained in the oxidized state by an excess of ferricyanide—an experimental arrangement which did not impair oxygen evolution. The diminished phosphorylation here did not seem to result from an inhibitory or uncoupling effect of the oxidized indophenol dye since the addition of the oxidized dye did not interfere with photophosphorylation when it was coupled to a non-cyclic electron flow from water to NADP (Table 3, ref. 8).

These findings were interpreted<sup>8,14</sup> as a separation of non-cyclic photophosphorylation by chloroplasts into two component light reactions: (a) photo-oxidation of water ( $\text{OH}^-$ ), an auxiliary reaction which did not form ATP but supplied electrons, at an intermediate reducing potential, to be used by (b) a second photochemical reaction, the bacterial type of non-cyclic phosphorylation, in which the reduction of NADP is coupled with photophosphorylation.

This interpretation seemed to receive additional support when Nozaki *et al.*<sup>15</sup> found a similar non-cyclic photophosphorylation in particles of photosynthetic bacteria. Thus, the site of non-cyclic photophosphorylation in plants was considered to be analogous to that in bacterial non-cyclic photophosphorylation and, in accordance with earlier formulations<sup>8,1</sup>, the same site was also shared by cyclic photophosphorylation.

The validity of these conclusions became open to some question after Trebst and Bok<sup>16</sup> found, and other investigators confirmed<sup>17-19</sup>, that dichlorophenol indophenol in a reduced form can catalyse cyclic photophosphorylation. The matter remained complicated because, under the conditions of the experiments of Losada *et al.*<sup>8</sup> with chloroplasts and of Nozaki *et al.*<sup>15,21</sup> with bacterial particles (strict anaerobicity and a great excess of ascorbate), dichlorophenol indophenol failed to catalyse any phosphorylation unless a non-cyclic electron flow from reduced dye to pyridine nucleotide was established and maintained.

The matter was finally resolved by the recent experiments with deaspidin which, at a low concentration, strongly inhibited the bacterial type of non-cyclic photophosphorylation but not the non-cyclic photophosphorylation associated with a flow of electrons from  $\text{OH}^-$  to NADP<sup>17,18</sup>. It became necessary, therefore, to abandon the previous hypothesis<sup>8</sup> and its later elaborations<sup>12,13</sup> in favour of a new hypothesis of cyclic and non-cyclic photophosphorylation which fits the new results and which is not in conflict with the earlier findings on the relation between electron flow and photophosphorylation.

Fig. 2. Scheme for cyclic photophosphorylation

**Cyclic photophosphorylation.** Our new hypothesis envisages cyclic photophosphorylation in chloroplasts as including, under physiological conditions, phosphorylations that are coupled with a flow of electrons from excited chlorophyll to ferredoxin, and then from reduced ferredoxin to cytochromes  $b_6$  and  $f$  and back to chlorophyll (Fig. 2). We specify tentatively two phosphorylation sites in this cyclic electron transport chain but this does not exclude the possibility of additional phosphorylation sites.

We consider the cyclic electron transport chain and its coupled phosphorylation to be distinct from non-cyclic photophosphorylation of the plant type (with  $\text{OH}^-$  as the electron donor) which we will discuss later. This conclusion is based on the fact that ferredoxin-catalysed cyclic photophosphorylation will occur only under conditions when non-cyclic photophosphorylation is excluded: (a) either by the use<sup>18</sup> of such specific poisons of electron flow from  $\text{OH}^-$  as *p*-chlorophenyl dimethylurea<sup>22</sup> (CMU) and 3-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU), or (b) by the use<sup>8</sup> of monochromatic light longer than 700 mμ which cannot support the non-cyclic electron flow from  $\text{OH}^-$  and the resultant oxygen evolution.

We include the chloroplast cytochromes<sup>24,25</sup>  $b_6$  and  $f$  as electron carriers in cyclic but not in non-cyclic photophosphorylation although, so far as we are aware, there is no direct evidence for the involvement of chloroplast cytochromes in either type of photophosphorylation. Indirect evidence comes from inhibition of ferredoxin-catalysed cyclic photophosphorylation by antimycin A and 2,4-dinitrophenol, two well-known inhibitors of oxidative phosphorylation where the direct participation of cytochromes is well documented. Antimycin A inhibition of oxidative phosphorylation is considered to be indicative of the participation of cytochrome  $b$  in electron transport<sup>26,27</sup>. It is likely that participation of cytochrome  $b_6$  accounts for the sensitivity of ferredoxin-catalysed cyclic photophosphorylation to antimycin A. As for cytochrome  $f$ , its joint participation in an electron transport chain with cytochrome  $b_6$  of chloroplasts is considered likely by analogy with oxidative phosphorylation in

mitochondria. The span between the redox potentials of cytochromes  $b_6$  and  $f'$  ( $-0.06$  V and  $0.365$  V, respectively) is large enough to accommodate a phosphorylation. Likewise, the span between the redox potentials of ferredoxin ( $-0.43$  V) and cytochrome  $b_6$  is large enough to accommodate at least one phosphorylation in this segment of the cyclic chain.

As discussed elsewhere<sup>12,14</sup>, we consider that in chloroplasts the ferredoxin-catalysed cyclic photophosphorylation is the physiological one. However, experimentally, cyclic photophosphorylation proceeds readily without ferredoxin when catalysed by one of several dyes or other co-factors. Since such artificial cyclic photophosphorylations are resistant to inhibition by antimycin A, it seems reasonable to conclude that they bypass the cytochrome  $b_6$  site (see dotted line in Fig. 2).

**Bacterial type of non-cyclic photophosphorylation.** To account for the results with desaspidin, we now propose a new scheme for the bacterial type of non-cyclic photophosphorylation (Fig. 3). Under strongly reducing conditions (great excess of ascorbate and in the presence of DCMU) no cyclic electron flow is possible since the components of the cyclic chain will be kept in the reduced state (cf. refs. 38, 39, 31). However, under these conditions, electrons will flow unidirectionally via a portion of the cyclic chain to ferredoxin (and NADP). As long as this unidirectional or non-cyclic flow of electrons through a cytochrome is maintained, it would induce a phosphorylation at a 'cyclic' site. This mechanism would explain the two characteristic features of non-cyclic photophosphorylation of the bacterial type: ATP formation at a cyclic site, as indicated by desaspidin inhibition, and the dependence on a non-cyclic electron flow, as indicated by the requirement for the terminal electron acceptor<sup>31,32</sup>.

Fig. 3 (thick arrows) shows how the proposed scheme explains non-cyclic photophosphorylation of the bacterial type induced in chloroplasts when dichlorophenol indophenol is the electron carrier between ascorbate and the cyclic chain. Moreover, the scheme also explains the generation of a non-cyclic photophosphorylation of the bacterial type in chloroplasts with *p*-phenylenediamine which was introduced, with its derivatives, into the study

Table 2. EFFECT OF DESASPIDIN ON THE BACTERIAL TYPE OF NON-CYCLIC PHOTOPHOSPHORYLATION

Treatment	NADP omitted		NADP added	
	ATP formed ( $\mu$ moles)	ATP formed ( $\mu$ moles)	NADP reduced ( $\mu$ moles)	
<i>p</i> -phenylenediamine	0.06	1.23	3.83	
<i>p</i> -phenylenediamine and desaspidin		0.03	3.93	
2,6-dichlorophenol indophenol	0.04	1.69	3.18	
2,6-dichlorophenol indophenol and desaspidin		0.06	3.54	
2,3,5,6-tetramethyl- <i>p</i> -phenylenediamine (DAD)	0.04	2.97	4.06	
DAD and desaspidin		0.05	3.83	
No co-factor added		0.02	1.27	

The experimental conditions were as given for Fig. 1 for the non-cyclic system, except that 100  $\mu$ moles of Na ascorbate and  $2 \times 10^{-4}$  M 2-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU) were added to the reaction mixture. 0.1  $\mu$ mole 2,3,5,6-tetramethyl-*p*-phenylenediamine (diaminodurel), 1.0  $\mu$ mole *p*-phenylenediamine, and 0.1  $\mu$ mole 2,6-dichlorophenol indophenol were added as indicated.

Table 3. EFFECT OF DESASPIDIN ON CYCLIC PHOTOPHOSPHORYLATION CATALYSED BY SUBSTITUTED PHENYLENES AND 2,6-DICHLOROPHENOL INDOPHENOL

Treatment	ATP formed ( $\mu$ moles)	
	Control	+ Desaspidin
<i>p</i> -phenylenediamine	1.30	0.03
2,3,5,6-tetramethyl- <i>p</i> -phenylenediamine	4.01	0.07
2,6-dichlorophenol indophenol	1.40	0.04
No co-factor	0.06	

The experimental conditions were as given for Table 2, except that ascorbate and NADP were omitted and the illumination time was 30 min. The reaction mixture was pre-illuminated 1 min before the addition of 2-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU).

of photophosphorylation by Trebst<sup>33</sup>. These compounds are known to interact with the cytochrome chain in oxidative phosphorylation<sup>31</sup>.

Trebst<sup>33</sup> has shown that *p*-phenylenediamine can induce in chloroplasts what, in our terminology, would be a non-cyclic electron flow of the bacterial type to NADP, but he found no accompanying phosphorylation. Table 2 shows that in the presence of a higher concentration of the co-factor and a great excess of ascorbate the non-cyclic electron flow to NADP was accompanied by a significant phosphorylation. Similar results were obtained with 2,3,5,6-tetramethyl-*p*-phenylenediamine (diaminodurel), with which Trebst and Pistorius<sup>34</sup> did obtain a phosphorylation coupled to a bacterial type non-cyclic electron flow to NADP, and with dichlorophenol indophenol. In all three cases phosphorylation was strongly inhibited by  $5 \times 10^{-7}$  M desaspidin and was strictly dependent on the non-cyclic electron flow to ferredoxin and thence to NADP. However, the phosphorylations were poorly coupled to electron flow, resulting in a poor stoichiometry between the NADP reduced and ATP formed.

Table 3 shows that, in the absence of NADP and ascorbate, the phenylenediamine compounds and dichlorophenol indophenol catalysed a cyclic photophosphorylation which was as strongly inhibited by desaspidin as the respective bacterial type non-cyclic photophosphorylations catalysed by the same compounds (Table 2).

We conclude, therefore, that in chloroplasts the non-cyclic photophosphorylation of the bacterial type depends on a unidirectional, non-cyclic electron flow over a portion of the cyclic chain and involves a phosphorylation at a cyclic site. This formulation fits not only the facts in chloroplasts but also those pertaining to the non-cyclic phosphorylation observed with chlorophyll-containing particles from photosynthetic bacteria<sup>31,32</sup>. There again, the phosphorylation occurred in the presence of a great excess of ascorbate which precluded cyclic photophosphorylation and was dependent on a non-cyclic electron flow from ascorbate via dichlorophenol indophenol to NAD.

In the light of present knowledge the observations which led us to the previous hypothesis<sup>9</sup> are also in agreement with the new hypothesis. ATP was not formed in the presence of small amounts of dichlorophenol indophenol and large amounts of ferricyanide because excess ferricyanide kept the dichlorophenol indophenol in an oxidized state known to uncouple phosphorylation. We can also explain now why the addition of oxidized di-

Fig. 3. Scheme for non-cyclic photophosphorylation of the bacterial type

Fig. 4. Scheme for non-cyclic photophosphorylation of the plant type

chlorophenol indophenol to the NADP system did not uncouple phosphorylation: the dye was probably quickly reduced by ferredoxin and, once reduced, it no longer uncoupled phosphorylation<sup>44</sup>.

**Non-cyclic photophosphorylation of the plant type.** Our present concept of non-cyclic photophosphorylation in plants is shown in Fig. 4. The phosphorylation is envisaged as being coupled to the oxidation of  $\text{OH}^-$ , a coupling that would account for the consistent stoichiometry,  $P/2e = 1$ , between oxygen evolution and ATP formation. An electron from  $\text{OH}^-$  is transferred via chlorophyll to ferredoxin in a single light reaction. In isolated chloroplasts, ferredoxin may be replaced by non-physiological electron acceptors (Hill reagents) with an attendant drop in the light-generated reducing potential. Fig. 4 (dotted lines) illustrates this for ferricyanide and benzoquinone (BQ).

The 'chlorophyll' in Fig. 4 represents the complex of chlorophyll *a* and *b* pigments in their various forms and includes those accessory pigments which are involved in light absorption by chloroplasts (see refs. 43, 44). In Nature, photosynthesis occurs usually in white light, hence both cyclic (Fig. 2) and non-cyclic photophosphorylation receive light of the same complete spectral composition. We assume that excitation energy is transferred among the chloroplast pigments with the great efficiency that is well documented in algal cells (see review by Duxens<sup>45</sup>).

In laboratory experiments with monochromatic light, it has been established that cyclic photophosphorylation (Fig. 2) and non-cyclic photophosphorylation of the bacterial type (Fig. 3) can occur at wave-lengths longer than 700 mμ that will not support non-cyclic photophosphorylation of the plant type\* (Fig. 4). Thus, it appears that plant non-cyclic photophosphorylation requires the shorter wave-lengths of light and is perhaps most efficient at wave-lengths not longer than those at which photosynthesis occurs with maximum efficiency. The energy balance given in Table 4 shows that 1 quantum of light at 680 mμ—the longest wave-length that would still support maximum efficiency of plant photosynthesis<sup>46</sup>—contains sufficient energy for the transfer of an electron

from  $\text{OH}^-$  to ferredoxin and the coupled phosphorylation.

The electron pathway from  $\text{OH}^-$  to chlorophyll is the least-understood part in the mechanism of photosynthesis and its elucidation must be left to future research. Only a few of the co-factors and catalysts involved therein are now known: chloride ions<sup>46, 47</sup>, manganese<sup>48, 49</sup> and plastoquinone<sup>50-52</sup> (plastoquinone is also involved in cyclic photophosphorylation in chloroplasts<sup>51, 53</sup>). The nature of the linkage between electron flow from  $\text{OH}^-$  and phosphorylation remains obscure but there is good reason to believe that the two are closely linked in Nature since the rate of electron flow from  $\text{OH}^-$  is greatly increased by the concurrent phosphorylation<sup>5, 44-55</sup>.

The flow of electrons from  $\text{OH}^-$  to ferredoxin, and the resultant oxygen evolution, are easily susceptible to damage when chloroplasts are removed from intact cells (see review<sup>44</sup>). The non-cyclic electron flow of the bacterial type is much more stable but, again, it is also uncertain whether it can give a true measure of the efficiency of electron transport in the intact cell. It is not surprising, therefore, that a requirement of one quantum per electron transferred to ferredoxin (or NADP) has not been obtained in investigations with isolated chloroplasts<sup>57</sup>.

**Cyclic and non-cyclic photophosphorylation as the two light reactions of photosynthesis.** In plant photosynthesis non-cyclic photophosphorylation (equation 1) provides reduced ferredoxin, ATP and  $\text{O}_2$  in a stoichiometry of 4:2:1. Since two moles of reduced ferredoxin are required to give one mole of  $\text{NADPH}_2$ , non-cyclic photophosphorylation gives rise to  $\text{NADPH}_2$  and ATP in a ratio of 1 to 1. Were this ratio adequate for carbon assimilation there would be no need for cyclic photophosphorylation. However, the carbon reduction cycle appears to have a requirement of 2  $\text{NADPH}_2$  and 3 ATP per 1 mole of  $\text{CO}_2$  assimilated to the level of sugar<sup>58</sup>. Additional ATP is required to form starch, the main carbohydrate product of photosynthesis in leaves. (ATP is expended in the formation of adenosine diphosphate glucose from which the glucosyl moiety is transferred to a starch primer<sup>59</sup>.) Moreover, as was pointed out elsewhere<sup>6</sup>, cyclic photophosphorylation may be an important mechanism for providing the large supplies of ATP that are required for protein synthesis and for other endergonic processes in the cell.

If we accept cyclic and non-cyclic photophosphorylation as the two sub-divisions of the energy conversion process of photosynthesis, the relation between them becomes important. We have already cited the evidence<sup>12</sup> that in isolated chloroplasts cyclic photophosphorylation occurs only when non-cyclic photophosphorylation is stopped. As long as electrons move from  $\text{OH}^-$  to ferredoxin, and thence to NADP, cyclic photophosphorylation cannot proceed. We have presented evidence elsewhere<sup>12</sup> that the availability of oxidized NADP may regulate the flow of electrons via the cyclic or non-cyclic pathway.

We shall now examine how our hypothesis can explain some of the observations that are used to support the concept of 'two light quanta per one electron transferred'<sup>43-45</sup>. The 'red drop' (that is, the drop in the quantum efficiency of photosynthesis of intact plant cells in monochromatic light longer than 685 mμ) would mean in our scheme that at the longer wave-lengths of light non-cyclic photophosphorylation became limiting, thereby reducing the availability of  $\text{NADPH}_2$  and decreasing the over-all efficiency of the process. 'Enhancement'<sup>43-45</sup> (that is, the synergistic increase in the quantum efficiency of photosynthesis at long wave-lengths of light that results

Table 4. ENERGY BALANCE OF NON-CYCLIC PHOTOPHOSPHORYLATION OF THE PLANT TYPE

Energy input of 1 einstein, $\lambda = 680 \text{ m}\mu$ , is 43 kcal.
$\text{Ferredoxin}_{ox} = \text{ferredoxin}_{red} + e^-$ ; $E^\circ = -0.43 \text{ V}$ (pH 7).
$1/2 \text{H}_2\text{O} = 1/4 \text{O}_2 + \text{H}^+ + e^-$ ; $E^\circ = +0.82 \text{ V}$ (pH 7).
Potential span between $\text{O}_2$ and $\text{ferredoxin}_{red}$ is $1.25 \text{ eV} = 1.25 \times 23.06 = 28.8 \text{ kcal}$ .
Energy requirement (per 1 electron) to form 1 ATP: $10 \text{ kcal}/2 = 5 \text{ kcal}$ .
Excess of energy input over output. $43 - (28.8 + 5) = 8.2 \text{ kcal}$ .

Fig. 5 Joint scheme for cyclic and non-cyclic photophosphorylation in chloroplasts

from the addition of shorter wave-lengths) would mean that the addition of light of a shorter wave-length restored non-cyclic photophosphorylation, removed the shortage of reductant, and thereby enhanced the overall efficiency of photosynthesis.

Among the other observations that would fit the present hypothesis is the oxidation of cytochromes in longer wave-lengths of light and their reduction in shorter wave-lengths of light (see reviews in refs. 43 and 44). The photo-oxidation of cytochromes would be consistent with the onset of cyclic photophosphorylation at the longer wave-lengths and the reduction of cytochromes with the onset of non-cyclic photophosphorylation at the shorter wave-lengths of light. It is possible that electron pressure is so high during non-cyclic photophosphorylation that it tends to keep all the cytochrome components of the cyclic chain in a completely reduced state.

Similarly, some of the observations on the partial loss of photosynthetic activity in algal mutants<sup>45</sup> can be explained as indicating the loss of non-cyclic photophosphorylation of the plant type. The remaining photosynthetic activity would then be cyclic photophosphorylation and the non-cyclic photophosphorylation of the bacterial type.

### Concluding Remarks

The present hypothesis differs from that presented earlier<sup>1-10</sup> in not excluding the possibility that the partial reactions of photosynthesis may proceed with a high degree of efficiency, because of an efficient, resonance type transfer of energy between different photosynthetic pigments<sup>46</sup>, without invoking intervening dark reactions. Since most of our work has been with leaf chloroplasts, it is interesting to note that Warburg's recent experiments<sup>41</sup> show a high efficiency of photosynthesis in leaves: a requirement of 5.5 quanta per CO<sub>2</sub> as contrasted with his best earlier measurements<sup>42</sup> of about 15 quanta per CO<sub>2</sub>.

According to our earlier hypothesis, a transfer of one electron from water (OH<sup>-</sup>) to ferredoxin and NADP required the energy of two photons absorbed by two-pigment systems acting in series. We now consider that the energy of one photon absorbed in a single light reaction may be sufficient.

## MEASUREMENTS OF PHOTOSYNTHESIS AND RESPIRATION IN A MARINE DIATOM WITH THE MASS SPECTROMETER AND WITH CARBON-14

By DR. J. BUNT\*

Lamont Geological Observatory, Columbia University, Palisades, New York

FOLLOWING the introduction by Steemann Nielsen<sup>1</sup> of a carbon-14 technique for the measurement of organic production in the sea, widespread discussion has arisen concerning the meaning of data so gathered. Steemann Nielsen (Steemann Nielsen and Hansen<sup>2</sup>) has maintained his attitude that, in short-term experiments, something between net and gross photosynthesis is measured, basing his judgement on observed relative losses of carbon-14 from fully labelled algae in the light and in darkness. Ryther<sup>3</sup>, partly on the basis of similar experiments, concluded that the method measures net photosynthesis. Others (for example, see McAllister, Shah and Strickland<sup>4</sup>) have taken the view that the measurement represents increases in particulate carbon since appreciable amounts of organic substances may be excreted into the extra-cellular environment during the course of experiments. In assessing the carbon-14 technique, it has been usual to make reference to measurements of photosynthesis reflected in changes in dissolved oxygen in the suspending medium and, of necessity, to make the assumption that rates of oxygen consumption in the dark continue unaffected in the light. Evidence derived from mass spectrometer studies using isotopic oxygen by Brown<sup>5</sup> has been relied on for justification of this assumption.

In employing the carbon-14 technique to investigate the influence of temperature and light intensity on the photosynthetic activities of bacteria-free cultures of microalgae from Antarctic sea-ice (Bunt<sup>6</sup>), it was found the data were not fully compatible with any of the described interpretations. Among the evident anomalies, it was apparent that rates of respiration calculated according to the method of Steemann Nielsen and Hansen<sup>2</sup> were far too low when expressed as percentages of saturated rates of photosynthesis. In this respect it seemed that the uncorrected data could not be considered to represent net photosynthesis. Furthermore, the factor used by Steemann Nielsen and Hansen<sup>2</sup> to obtain values for corrected net photosynthesis could not be considered adequate. On the assumption generally applied by Steemann Nielsen, that respiration is 10 per cent of gross photosynthesis, it would have been necessary to assume that not 60 per cent but only around 10 per cent of respiratory CO<sub>2</sub> was in some way identical with that fixed during photosynthesis. Further, acceptance of this assumption indicated compensation intensities well above levels of illumination at which successful growth had been observed to take place. For example, at 7°C and 4°C compensation points of 80 and 35 ft.-candles respectively were indicated for the diatom *Fragilaria sublinearis*. This organism has been grown at light intensities at least down to 40 ft.-candles at 7°C and down to less than 10 ft.-candles at 4°C.

At temperatures of 4°C and down to -2°C, extrapolation of light curves from *F. sublinearis* and physiologically similar species based on intensities between 30 and 500 ft.-candles consistently indicated significant levels of activity in the dark, although corrected for dark activity. To avoid these obviously unacceptable results, it was necessary to measure activities at light intensities down to and below 5-ft. candles. In the ice habitat, light intensities during the summer period when growth takes place are typically around 10-20 ft.-candles and less. Measurements under such conditions and in these terms have limited meaning since the spectral quality of the light penetrating the thick sea-ice layer is quite unlike that of daylight. However, the degree of shade adaptation of these species will be evident.

Data thus obtained, when plotted against light intensity, commonly appeared to display two linear portions very similar in nature to the broken light curves described originally with *Chlorella* in terms of net oxygen exchange by Kok<sup>7</sup> and more recently by Jones and Myers<sup>8</sup>, and by Hoch, Owens and Kok<sup>9</sup>, who offer a rational explanation of the phenomenon from direct experimental evidence.

Finding it necessary to be able to explain the results described, we undertook oxygen exchange measurements with the mass spectrometer system recently devised by Hoch and Kok<sup>10</sup>. *Fragilaria sublinearis* was adopted as the experimental organism. Using the mass spectrometer with the advantages of a modified inlet system, Hoch, Owens and Kok<sup>9</sup> have recently examined the relation between photosynthesis and respiration in the two unrelated algae *Anacystis nidulans* and *Scenedesmus* sp. Their work, in particular with the former organism, has shown that light exerts two effects on the uptake of oxygen: an inhibition of true respiration evident at low intensities and a stimulation of oxygen consumption which increases with the rate of photosynthesis. Results with the diatom from the sea-ice have confirmed these observations (MS. in preparation). Further, it was found that the extent to which inhibition of respiration makes itself evident is dependent on temperature. The conclusion was reached that, at 10°C for this organism, in the absence of stimulated uptake, respiration when fully light-inhibited continues at about 25 per cent of the rate in the dark. Indirect evidence was obtained which indicates that inhibition may occur in light absorbed by accessory photosynthetic pigments, as well as in light absorbed principally by chlorophyll *a*, but that the onset of inhibition requires higher intensity at shorter wave-lengths.

Since the observed ratios of oxygen production to consumption have not been discussed previously, some of this information has been summarized in Table 1. Two separate ratios are given for each wave-length of light and temperature. PT/UT represents the ratio existing between total oxygen evolution (PT) and total consumption in the light (UT). The second ratio is equivalent to that used when changes in dissolved oxygen are measured and when it is assumed that oxygen consumption in the light and in darkness are identical. It will be noted that values of PT/UT are generally lower than P/R and that P/R in particular is influenced quite markedly by temperature and, to a lesser extent, by the wave-length of light used. In view of the differences in spectral quality of submarine light, such an effect could be of some ecological significance, since it will be observed also that at 10°C P/R is higher at 525 mμ than at 678 mμ, whereas the reverse is true at 3°C. The optimum growth temperature for *F. sublinearis* is around 5°C. At 3°C, which approximates the optimum, it should be indicated that dark respiration was approximately 9-14 per cent of gross photosynthesis. It would be expected that the true percentage, with respiration fully inhibited, would be appreciably lower.

Recognition of the fact that true respiration (that associated with the release of CO<sub>2</sub>) may be inhibited in the

light has particular significance in interpreting measurements of photosynthesis based on the uptake of radioactive carbon. It has been mentioned already that both Steemann Nielsen<sup>11</sup> and Ryther<sup>2</sup> have measured losses of carbon-14 from uniformly labelled cell suspensions in order to interpret observed uptake into unlabelled cells. Working with *Chlorella*, the former author found that losses of carbon-14 in the light amounted to 50–70 per cent of losses in the dark, while the latter, using *Dunaliella*, found losses to be insignificant in the light. These, and other considerations, led to a disparity of opinion. With the evidence from the mass spectrometer, it was felt that the results of these two investigators could well be essentially compatible. Accordingly, an attempt was made to confirm the observations with the mass spectrometer using the carbon-14 technique.

For this purpose, *F. sublinearis* was grown in the presence of  $\text{Na}_2^{14}\text{CO}_3$  until labelling was considered to be uniform. The cells were centrifuged and washed several times with fresh medium, allowed to stand in the dark for several hours in accordance with the recommendation of Steemann Nielsen<sup>11</sup>, centrifuged and washed several times further, and finally re-suspended in fresh medium such that the cell concentration, in terms of chlorophyll *a*, was 0.02  $\mu\text{g}/\text{ml}$ . At this concentration, the possibility of mutual shading on exposure to light would be negligible, good uniformity between replicates would be assured, and self-absorption in counting the activity of filtered cells would be unimportant. The cell suspension so prepared was distributed in calibrated 30-ml. Fernbach flasks and then exposed, not to a single light intensity, as had been the practice of Steemann Nielsen and Ryther, but to a range of light intensities as well as in the dark. Cool-white fluorescent lighting was employed. The flasks themselves were housed in a water bath at 7° C with temperature control effective to  $\pm 0.1^\circ\text{C}$ . After 8 h incubation, the cells were recovered on 'Millipore' filters and their activities were determined for comparison with the activities of aliquots filtered at the beginning of the experiment. Since the changes in activity were not expected to be great, accuracy was assured so far as was reasonably possible by recording the numbers of counts after 1 h or 800,000 counts, whichever occurred first.

The results are shown graphically in Fig. 1 with losses of activity in the light referred to losses in the dark. In general character, they were found to parallel the observation of inhibited respiration based on measurement of oxygen consumption in the light with the mass spectrometer. It will be observed that, with this organism and under these conditions, very low light intensities were sufficient to inhibit respiration. At full inhibition, which was probably saturated at 200 ft.-candles, losses of

Fig. 1. Inhibition of respiration in the light in terms of losses of carbon-14 from uniformly labelled *F. sublinearis*.

Fig. 2. The effect of adaptation to high and low light intensities on the inhibition of respiration in *F. sublinearis* at  $-2.0^\circ\text{C}$ . —, High light adapted; ---, shade adapted at  $7^\circ\text{C}$ .

carbon-14 were only around 20 per cent of those in the dark. No attempt has been made to apply these findings to values of carbon-14 fixation since to do so reliably would require carefully controlled experiments with labelled and unlabelled cells similarly preconditioned. Nevertheless, the implications of these results are clear and, together with the data from the mass spectrometer, they provide a means of explaining the anomalies described earlier. The fact that Ryther<sup>2</sup> was unable to demonstrate losses of carbon-14 from illuminated cells could have resulted from very marked, perhaps complete, inhibition of respiration under his experimental conditions.

Concerning this possibility, some evidence has been obtained which suggests that, in cells adapted to low light intensities, the onset of inhibition may require less light and may be more fully achieved than in cells accustomed to high light intensities. This effect is demonstrated in Fig. 2, which describes the losses of carbon-14 from uniformly labelled cells at a temperature of  $-2.0^\circ\text{C}$  following adaptation to high (400 ft.-candles) and low (20 ft.-candles) intensities at  $7^\circ\text{C}$ . It should be emphasized, however, that a parallel experiment run at  $7^\circ\text{C}$  throughout yielded less convincing results. While the existence of such an effect would be compatible with the suggestion of Hoch *et al.*<sup>9</sup> that inhibition of respiration may be mediated by the pigment P700 (see Kok<sup>12</sup>), the problem requires more careful study.

In summary, it must be concluded that, where excretion is insignificant, the carbon-14 method gives a measure of net photosynthesis. The precise interpretation of data in terms of gross photosynthesis is not simple, however, and requires a rather full knowledge of the extent to which respiration is inhibited under any given set of conditions. No obvious means of obtaining this information either directly or indirectly from measurements of carbon-14 fixation is evident. The process of inhibition is dependent on a number of factors including the nature of the pigment systems in the material being studied, the spectral quality and intensity of the illumination, and possibly temperature, as well as the general physiological condition of the organisms.

An additional and perhaps more serious complication is presented by algae which excrete significant amounts of organic carbon to the external environment in the course of growth. This process does not appear to be important in *F. sublinearis*, at least in actively growing cultures, and has not been considered in the present discussion.

While this study was based on a single species of organism, the view appears to be justified that inhibition of respiration under appropriate conditions is a general phenomenon among the algae, and presumably in other

groups of plant life also. Consequently, it is expected that the present findings should, in principle, have general relevance to an understanding of processes of primary production in the sea.

This work was supported by the National Science Foundation contract GB-1355. I thank Dr. G. Hoch, Miss O. Owens, and the Research Institute for Advanced Studies Laboratories at Baltimore for their help. The investigation was completed in Dr. Paul Burkholder's laboratories.

## EVIDENCE FOR NEUROGENIC CONDUCTION IN THE MAMMALIAN HEART

By Dr. C. J. G. WENSING

Institute of Veterinary Anatomy and Embryology, State University of Utrecht, Netherlands

IT is a widely accepted view that the generation and the conduction of impulses in the mammalian heart are of a myogenic nature. As a result of a comprehensive neuro-histochemical examination, however, we want to express our firm belief that this process is of a neurogenic nature, whereas the conduction of the impulse between the sino-auricular (SA) and the atrio-ventricular (AV) node has a direct nature and takes place through nerve fibres.

We chose the pig as our principal experimental animal, because it has highly differentiated Purkinje fibres. Hearts of dog and cat have also been examined, although in smaller numbers. Since the extent, as well as the structure, of the conductive system in the pig heart was insufficiently known, we examined it with the aid of ordinary nucleus-plasma stains. For the neuro-histochemical examination we used the acetylcholinesterase (AChE) reaction of Koelle and the Champy-Coujard method. Using a modification of the AChE reaction, we succeeded in tracing the course of nervous elements in thicker pieces (up to 5 mm) of tissue. An additional examination of the material has been made by the silver-impregnation method (Bielchowsky-Gros).

From the microscopic and macroscopic examination, it appeared that the conductive system in pig shows the same course and extensions as that in other ungulates<sup>1</sup>. The actual structures of the various parts of the system, however, did not agree with the descriptions to be found in the relevant literature. For example, the dimensions of the cross-sections of the cells of the SA and AV nodes, which are said to be smaller than those of the surrounding myocardial fibres, are, in fact, distinctly larger at many places. Consequently, it appears that, since the retardation of the impulse in the AV node is generally explained by pointing to the smaller dimensions of the cross-section of the nodal fibres, this is no valid argument in itself.

A muscular formation, consisting of thin, interconnected muscle fibres showing a considerable amount of connective tissue in the interfibrillar meshes, occurs in the sulcus terminalis, close to the SA node. In our opinion, this formation is often erroneously referred to as constituting the SA node, and this basic understatement has been a source of controversial statements.

It is impossible to show a direct connexion of specialized muscle fibres between the two nodes, although Purkinje fibres which pass into ordinary cardiac tissue can be sub-endocardially noted in the wall of the right atrium. These observations do not agree with the conclusions formulated by Robb and Petri<sup>2</sup> and by James<sup>3</sup>.

The number of Purkinje fibres in the myocardium is very small as compared with that of the myocardium fibres. This implies that, in the case of a myogenic conduction, the impulse would have to be propagated by ordinary muscle fibres.

The SA node in the adult as well as in the embryonic pig heart was easily marked by the AChE reaction, so that any doubt or inaccuracy concerning the exact location of the SA node has been definitely excluded. In the node, delicate interconnected fibres are marked by the precipitation and, as a whole, the structure gives the impression of a network with swellings at the junctions (Fig. 1). We are of opinion that this nervous network consists of small, interconnected cells. The more delicate structures can be properly studied in Champy-Coujard preparations.

Post-ganglionic nerve fibres in the node have been observed to make contact with the aforementioned network. Moreover, there is a considerable number of pre- and post-ganglionic fibres and ganglion cells in the immediate neighbourhood of the node. The ganglion cells could not be found in the node proper. In Champy-Coujard preparations, the SA node is extremely well marked by the black-stained nervous elements, so that the structure of the network can be seen more readily. It appears to consist of small interconnected nerve fibres, the extensions of which entwine every nodal cell (Fig. 2). In our opinion, this dense network is built up by the autonomic interstitial cells (AIC) of Cajal, which may be looked on as primitive ganglion cells. Moreover, post-ganglionic nerve fibres can be seen in these preparations, which terminate on the network. In microscopic preparations it is very difficult to check the correctness of this interpretation, and electron-microscopic examination is required.

Identical structures may be observed in the Champy-Coujard preparations of the hearts of dog and cat. The

Fig. 1. SA node. Embryo of pig, 70 days. Staining AChE. Positive reaction in and around the SA node. The nervous component of the node is marked by precipitation. This component consists of cells with long extensions (arrow). These cells form a network. Ganglia at the outside of the node (arrow). ( $\times 24$ )

AIC network dominates the picture and there are also post-ganglionic fibres in these animals which probably terminate on the network.

The AV node can also be marked with the AcChE reaction. The microscopic structure of the nerve fibres which have been marked by precipitation differs fundamentally from that of the nervous elements in the SA node. The nerve fibres in the AV node are post-ganglionic and form a very dense plexus (Fig. 3). The use of serial frozen sections of the AV node in the embryonic pig heart showed that the nerve plexus has a different structure in its various layers. The most pronounced plexiform structures have been found in its central layer. In sections cut parallel with the endocardium, nerve fibres could be observed on the basal side of, and entering, the AV node. In sections of the right atrium between the two nodes, nerve fibres could be demonstrated in such numbers that we gained the impression that there is a nervous connexion between the two nodes, but we were unable to verify this impression by frozen sections. We therefore submitted the whole of the right atrium situated between the nodes to the AcChE reaction followed by dehydration and plastic embedding, so that it was made accessible to microscopic examination. These transparent plastic preparations have provided a three-dimensional reconstruction of the course of the nerve fibres. In this way a nervous connexion between the two nodes could be traced with fair certainty (Fig. 4).

Fig. 2. SA node of adult pig. Staining Champy-Coujard. The brightly stained nodal cells are surrounded by black stained nerve fibres which interconnect and form a network (A.I.C. of Cajal with extensions—arrow). Cut parallel with the epicardium. ( $\times c. 214$ )

Fig. 3. Medial right atrial wall and septum atriorum. Embryo, 80 days. Staining AcChE. Nerve plexus in the AV node. No reaction in the proper nodal cells. Nerve fibres running from SA to AV node, but no uninterrupted connexion. SA node (left upper side) just outside the photograph. Cut parallel with the endocardium. ( $\times 24$ )

Fig. 4. Stereometric plastic preparation of a part of the right atrium. Embryo, 62 days. Staining AcChE. The nerve fibres between the two nodes may be followed up to the sulcus terminalis (arrow). The AV node and the His bundle are clearly marked by their nervous components.

Fig. 5. AV node of adult pig. Staining Champy-Coujard. Post-ganglionic nerve plexus with a number of AIC in its meshes (arrow) ( $\times c. 214$ )

The results obtained by examination of the AV node have been confirmed in Champy-Coujard preparations, which are more suitable for examination at higher magnifications. AIC are also demonstrable in the meshes of the post-ganglionic nerve plexus. Their number is not so great as in the SA node, but there are definitely more AIC here than in the ordinary cardiac musculature (Fig. 5).

With the aid of this method similar nervous elements could be shown to exist in the heart of the dog and cat; in these species, the intensive formation of plexuses is very conspicuous.

Nerve fibres can be marked by the AcChE reaction alongside the His bundle and the peripheral Purkinje fibres. They are predominantly post-ganglionic fibres, which have issued from the nerve plexus in the AV node and run alongside the bundle and the peripheral Purkinje ramifications into the myocardium. Moreover, the bundle is accompanied by some myelinated, probably afferent, nerve fibres.

In the pig heart, ganglion cells in or alongside the bundle could not be found, although a number occur at the basal side of the AV node, alongside the nerve fibres connecting the SA and AV nodes. Such ganglion cells could not be observed at the apical side of the node.

The myocardium is penetrated by nerve fibres accompanying Purkinje fibres as well as by those which accompany the arborizations of the coronary vessels. It appears that a morphological distinction between these two types is possible: the former issue sub-endocardially and reveal a fundamentally aberrant mode of ramification<sup>4</sup>.

Fig. 6. Myocardium of ventricle Embryo, 60 days. Staining Champy-Coujard, A.I.C. with extensions along muscle fibres (arrow) ( $\times$  c. 214)

The result obtained with the aid of the AcChE reaction can be confirmed in Champy-Coujard preparations. Apart from post-ganglionic fibres, AIC can be demonstrated alongside the bundle. Furthermore, some AIC can be shown intramyocardially in Champy-Coujard preparations (Fig. 6). In our opinion these cells form an extensive intramyocardial network, which is interconnected with the muscle fibres. Using the silver impregnation method it has been possible to demonstrate nervous tissue in many parts of the conductive system, but this method does not reveal the exact extent of these elements alongside the conductive system, since its results are too variable. The method is, however, useful in detailed investigation.

It is apparent that many serious objections can be raised against the classic theory of myogenic conduction in the heart. First, the conduction of the impulse in the right atrium has not been satisfactorily explained; the explanation of the wave-like propagation of the impulse through ordinary muscle fibres is illogical and inadequate. Secondly, the histological structure of the two nodes provides no sound basis to explain their function. The peculiar shape of the fibres in the AV node and their smaller cross-section, which have been used as arguments to explain the retardation of the impulse, are not applicable to the situation in the pig heart. Thirdly, the number of penetrating Purkinje fibres in the myocardium, especially in embryos, is very small, so that a single Purkinje fibre would have to activate a considerable number of myocardium fibres. In view of the non-syncretic nature of the cardiac musculature, the occurrence of this type of activation is questionable.

Fourthly, it is highly improbable that the solitary Purkinje fibres in the right atrium have a conductive function. It is logical, therefore, to ask what their function is, as well as that of the Purkinje fibres in other parts of the heart. Our own conclusions may be enumerated as follows:

(1) The generation and conduction of the impulse in the mammalian heart are neurogenic, not myogenic, processes.

(2) The dense network of AIC in the SA node induces the generation of the impulse which leads to contraction. This is probably caused by neuro-secretory products from the AIC. The varicose character of the extensions of these cells points strongly in that direction.

(3) The conduction of the impulse in the right atrium toward the AV node takes place through nerve fibres, connecting the SA and the AV nodes.

(4) The retardation of the impulse in the AV node is caused by the plexiform nervous component in this node; the central layer with its intensive formation of meshes must play an important part in this retardation. The network of AIC between the meshes of this plexus may be responsible for the Tawara-rhythm of this node. Since the network is less dense than that in the SA node, the

Tawara-rhythm will reveal a lower frequency in the AV node.

(5) Beyond the AV node, conduction takes place through post-ganglionic nerve fibres, which run alongside the His bundle and its two branches.

(6) The transmission of the impulse to the muscle fibres takes place through AIC, which are omnipresent between the myocardium fibres.

Apart from the fact that the existence of the required nerve fibres has been demonstrated, the following arguments apply:

(1) Bethe and Boxler<sup>1</sup> pointed to the great physiological resemblance which exists between the rhythmic contractions of the jellyfish and the pulsations of the heart. The marginal nervous organ, constituting the pacemaker in jellyfish, shows a perfect physiological similarity with the SA node. From our examination it appeared that there is a definite morphological resemblance between the network of AIC in the SA node and the network in the marginal nervous organ in the jellyfish. Consequently, it is logical to assume an identical function for both structures.

(2) The place at which we were able to show nerve fibres between the SA and AV nodes coincides with that at which Paes de Carvalho<sup>2</sup> demonstrated electrophysiological pathways of faster conduction.

(3) The shape and the structure of the nervous component in the AV node are compatible with our explanation of its function. A conduction in a plexus will proceed less quickly than that in a longitudinally straightened structure. Moreover, we find the most intensive plexiform structures in the node exactly at the place at which Paes de Carvalho<sup>2</sup> was able to demonstrate the greatest retardation of the impulse. The influence of acetylcholine on the AV node—either a retardation in conduction or a complete block in the case of a lingering or a highly concentrated administration—may be readily explained. It is essential, therefore, to refer to the theory of conduction in axons as has been established by Nachmansohn<sup>3</sup>. According to this author, conduction along axons is not a purely physical but rather a combined physico-chemical process. The liberation of acetylcholine depolarizes the axon-membrane, whereas the enzyme acetylcholinesterase restores the rest-situation by the hydrolysis of the liberated acetylcholine. Administration of additional acetylcholine has the same effect as the use of eserine or DFP, since these compounds prevent the conduction along the axon by blocking the action of AcChE. The action of acetylcholine depends on the permeability of the axon-membrane. In ordinary myelinated nerves, this penetration may be impossible, but, on the other hand, it is quite comprehensible in post-ganglionic unmyelinated fibres in the AV plexus. Any influence of acetylcholine on the nodal fibres must be neglected, since this would involve the occurrence of acetylcholinesterase in these fibres. In the pig, this is not the case, except for the nervous elements around the nodal fibres.

(4) The extension of the nervous elements in the myocardium is such that every muscle fibre contacts nervous elements. According to Meyling<sup>4</sup> and Boeke<sup>5</sup>, AIC may act autonomically at the periphery. This action may give a reasonable explanation for the contraction of small pieces of cardiac tissue which are entirely isolated from the conductive system.

## STRETCH-INDUCED UTERINE GROWTH, PROTEIN SYNTHESIS AND FUNCTION

By PROF. A. CSAPO, DR. T. ERDOS, DR. C. R. de MATTOS, E. GRAMSS and C. MOSCOWITZ

Department of Obstetrics and Gynecology, Washington University, St. Louis, U.S.A.; Maternity Department and Department of Biochemistry, University of Bahia, Brazil; and Laboratoire d'Enzymologie, CNRS, Gif-sur-Yvette, Seine-et-Oise, France

**I**N the work recorded here the question was examined whether chronic stretch alone, without the endocrine support of the ovaries and the placentae, initiates uterine growth, protein synthesis and function.

In the fifteenth century the sawgilders had already noticed that ovariectomy results in castrate atrophy. Later experimental work demonstrated a loss of myometrial function during atrophy, which could be reversed by oestrogen<sup>1</sup>. It was also shown that distension promotes uterine growth and that this growth response is modified by the ovarian hormones. The conclusion was advanced that uterine growth can be generated by tension exerted on the myometrium<sup>2</sup>.

The isolation of the contractile proteins permitted the demonstration that oestrogen regulates the contractile system<sup>3</sup> and working capacity<sup>4</sup> of the myometrium, as well as the protein synthesis in the uterus<sup>5</sup>, while progesterone controls the involution process<sup>6</sup>.

We noted that a physical factor alone, namely, chronic stretch, has a powerful regulatory effect on uterine growth, protein synthesis and function when we ovariectomized parturient rabbits and filled their two uterine horns with balloons of different volumes. The uterine horn in which the parturient volume was restored remained structurally normal and displayed increased function, while the control horn of the same uterus, only carrying an empty balloon, underwent involution, castrate atrophy and a loss of contractile function.

Since in these *post-partum* rabbits both ovarian and placental endocrine functions were suspended, the structural and functional differences in the two horns of the same uterus could only be explained by their different volumes. For even if these uteri were exposed to a hypothetical endocrine effect (of the adrenals or other glands) the two horns must have been equally affected. This argument permitted the tentative conclusion that chronic stretch by itself not only promotes growth but also powerfully regulates uterine biology.

In the experiments reported here we examined non-pregnant as well as parturient rabbits. Rabbits were selected for investigation not only because a suitable method has already been worked out in this animal but also because the two anatomically and functionally independent uterine horns offer a control and an experimental uterus in the same rabbit.

Our operative and recording techniques were described earlier<sup>7</sup>. During surgery we photographed the uterus, introduced condom rubber balloons into both uterine horns and ovariectomized the animal. One balloon in the experimental horn was then filled with 100–120 ml. physiological saline, imitating the parturient volume, if the animal was pregnant, or up to 10 ml. volume if non-pregnant. The other balloon in the control horn was only in-

jected with a few ml. fluid during recording. A polyethylene outlet of the balloon permitted the repeated study of the intra-uterine pressure during 10 days of observation. After 10 days the animals were killed, the uterine horns excised, photographed, weighed and subjected to histological and biochemical analysis (wet and dry weights, protein, DNA and RNA).

After 4 days' pre-treatment of the non-pregnant rabbits with 25 µg/day oestradiol in oil intramuscularly the animals were divided into groups of three, depending on their subsequent treatment. The groups were the following:

(1) *Post-partum*, ovariectomized, untreated; (2) non-pregnant, untreated; (3) non-pregnant, ovariectomized, untreated; (4) non-pregnant, ovariectomized, 25 µg/day oestrogen; (5) non-pregnant, ovariectomized, 5 mg/day progesterone; (6) non-pregnant, ovariectomized, 25 µg/day oestrogen plus 5 mg progesterone.

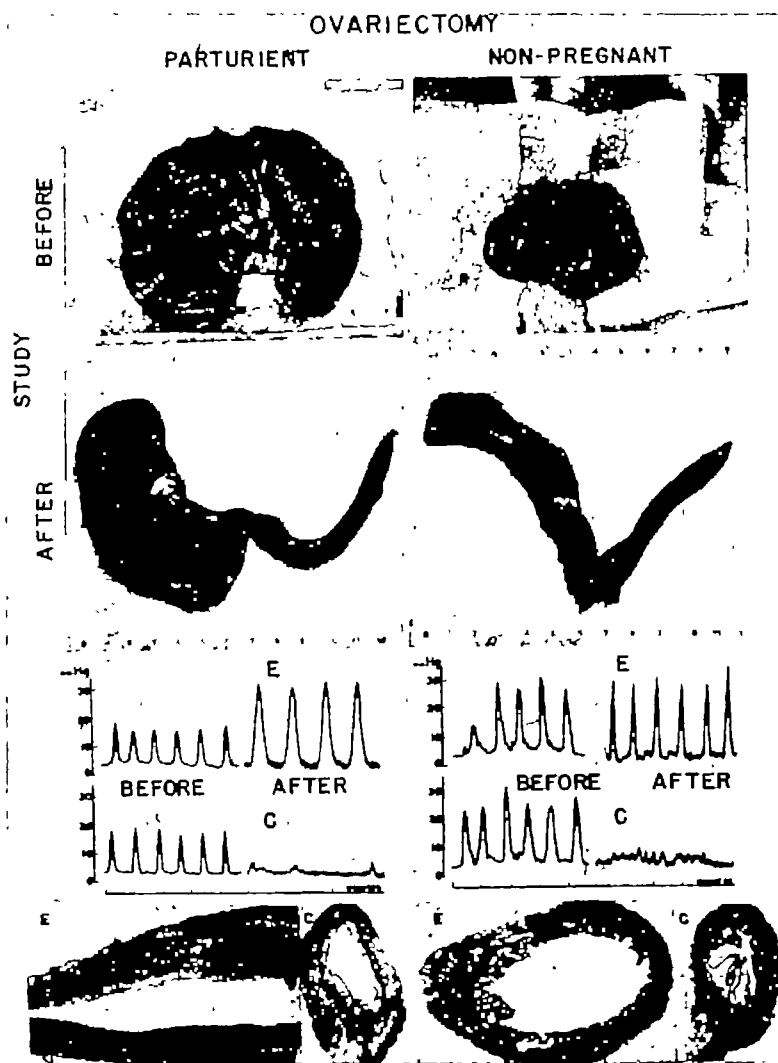

Fig. 1. Anatomical, functional, and structural differences between the two uterine horns of the same uteri induced by chronic stretch.

Fig. 1 illustrates the anatomical, structural and functional differences between the two uterine horns of the same uteri induced by chronic stretch in ovariectomized pregnant and non-pregnant rabbits. All animals, regardless of their treatment, showed this stretch-induced difference between the experimental and control horns.

Table 1 illustrates the differences between experimental and control horns, in wet and dry weights, in the weight ratios: experimental/control horns and in the RNA/DNA ratios. The experimental horn in all non-pregnant rabbits is 83–100 per cent heavier than the control horn. In the pregnant rabbits the difference is 400 per cent. However, while in the pregnant animals the difference is largely due to the involution of the control horn, in the non-pregnant animals it seems to be due to hypertrophy in the experimental horn. It would appear, therefore, that chronic stretch not only prevents involution and castrate atrophy but, like oestrogen, initiates uterine growth.

That this stretch-induced growth is not due to an increased uptake of water is shown by the fact that the wet and dry weight ratios of the experimental and control horns are almost identical. Protein and RNA determinations revealed a 7.8 per cent average protein and 6 per cent RNA/g increase in the experimental horn, as compared to the control horn. The fact (Fig. 1) that the intra-uterine pressure increased with the lapse of time during chronic stretch suggests that this protein increase in the experimental horn is partly due to an increased synthesis of the contractile protein complex, actomyosin.

Significant is the finding that the differences between experimental and control horns developed in spite of a blocking action, imposed on the uterus by progesterone treatment. Thus, stretch-induced myometrial hypertrophy is independent of uterine activity.

The results also suggest that oestrogen and chronic stretch have a synergistic action on uterine growth; that progesterone does not contribute to this process, in fact it may even decelerate it. However, these conclusions are tentative, for final proof rests on further experiments with a highly standardised colony of inbred animals.

Table 1 also presents the ratios RNA/DNA in the experimental and control horns. The fact that the RNA/DNA ratios are higher in the experimental horn is

Table 1. DIFFERENCES BETWEEN EXPERIMENTAL AND CONTROL HORNS IN WET AND DRY WEIGHTS, IN THE WEIGHT RATIOS: EXPERIMENTAL/CONTROL HORNS, AND IN THE RNA/DNA RATIOS

R	1.84	1.86	2.12

considered as evidence that the growth of the experimental horn is due to hypertrophy rather than hyperplasia.

The significance of this study lies in the demonstration that a change in the configuration of the myometrial cell profoundly alters its biology. This relationship between cell structure and function may be operative in a variety of cells, as a common regulatory device. In uterine biology the relationship is interesting in view of the growing uterine contents during pregnancy, uterine tumours, menstrual bleeding, etc. The relationship also suggests a possible mechanism for the action of intra-uterine contraceptive devices. After all, such a device is an imposed intra-uterine resistance which may alter the normal cyclic activity of the uterus during chronic application.

## GROWTH AND NEUTRALIZATION OF THE TRACHOMA AGENT IN MOUSE LUNGS

By DORIS M. GRAHAM

Medic Research Council Trachoma Research Unit, Lister Institute of Preventive Medicine, London, S.W.1

SEVERAL workers have investigated the behaviour of trachoma agents in the mouse lung. Bernkopf<sup>1</sup> found that the susceptibility of mice to the lethal effects of the T'angf strain given intranasally diminished with age until they were 6 weeks old, when they were completely resistant; the Dari strain did not kill mice of any age. By contrast, Watkins and Mackenzie<sup>2</sup> killed mice more than 6 weeks old by inoculating the T'angf strain intranasally. They failed to detect any increase in infective virus during the first week after inoculation and to detect infective virus after the second passage in mouse lungs, although they had some evidence for the presence of virus specific antigens in the lungs up to the ninth passage.

I have found no difference in the susceptibility of mice 3–6 weeks old to the lethal effects of the T'angf strain administered intranasally. Furthermore, I obtained evidence that the agent multiplies in the lungs and that the mice can be protected by previous immunization. The strains used are designated according to Gear *et al.*<sup>3</sup>, and their original names, used in this report, are given in brackets. TRIC/China/Peking-2/OT (ref. 4) (T'ang);

TRIC/SAU/HAR-2/OT (ref. 5) (SA2); TRIC/USA-CAL/CAL-2/OT (ref. 6) (ASGH); TRIC/WAG/MRC-1/OT (ref. 7) (G1); TRIC/WAG/MRC-17/OT (ref. 8) (G17); variants that kill chick embryos comparatively quickly are designated\* by the letter f, as, for example, T'angf.

Virus pools were prepared from heavily infected yolk sacs from live embryos and stored at  $-80^{\circ}\text{C}$ . Mice of the TO strain were used throughout. They were anaesthetized with a freshly prepared mixture of 2 parts ether to 1 part chloroform<sup>18</sup>; when they were breathing deeply and regularly, 0.1 ml. of virus suspension was dropped on to their nostrils. For infectivity titrations, 5–8 mice were inoculated with a number of 3.16-fold dilutions and were observed for 6 days. The titre of each suspension was expressed as the reciprocal of the dilution which killed 50 per cent of the mice within 6 days ( $MLD_{50}$ ) calculated by the method of Reed and Muench<sup>14</sup>. The lungs of all dead mice were completely consolidated, and the mean day of death of the mice was inversely related to dose of virus. The titres obtained from replicate titra-

\*Fifty per cent mouse lethal dose.

tions of the T'angf strain in mice aged 3, 4, 5 and 6 weeks had a standard deviation of  $\pm 8$  per cent and dose response curves did not differ greatly (Fig. 1).

To determine whether the trachoma agent multiplied in the mouse lung, large groups of 3-week-old mice were inoculated intranasally with yolk sac suspensions containing approximately 0.5 MLD<sub>50</sub> of T'angf or of G17. The titre of the inoculum was determined by simultaneous titration in mice and in chick embryos. At intervals, five mice were killed, their lungs removed aseptically, pooled and ground in 5 ml. of phosphate-buffered saline<sup>13</sup> containing 500 µg/ml. of streptomycin sulphate and titrated in the yolk sacs of 7-8-day-old chick embryos. Eggs were incubated at 35° C and candled daily. Titrations were terminated at 13 days, and titres of the lung suspensions were calculated in terms of 50 per cent egg lethal doses (ELD<sub>50</sub>). Fig. 2 shows the percentage of virus recovered from the lung plotted against time. Some mice died in each of the experiments; although the inocula varied from 0.4 to 1.1 MLD<sub>50</sub>, most mice died on the fourth day after inoculation.

Immediately after the anaesthetized mice had revived, all the virus inoculated could be recovered from their lungs. By the second day the titre had increased almost ten-fold, was greatest on the fourth day and slowly decreased thereafter.

By mixing virus suspensions with antiserum before intranasal inoculation, Bernkopf neutralized the T'angf strain with antisera against the T'angf and Dari strains of trachoma<sup>1</sup>. Using this technique, I neutralized the SA2f and G1 strains with both homologous and heterologous antisera.

Mice can be actively immunized against the toxic effects of trachoma strains administered intravenously<sup>12,16</sup>. In order to determine whether mice could be protected

Fig. 1. Relation of time of death of mice of different ages to dose of the T'angf strain inoculated intranasally. Mice aged: 3 weeks, ●; 4 weeks, ○; 5 weeks, ▲.

Fig. 2. Growth of two strains of trachoma in the mouse lung. Infecting dose: ●, SA2f 1.1 MLD<sub>50</sub>; ○, G17 0.4 MLD<sub>50</sub>.

from the lethal effects of these agents inoculated intranasally, the technique of intravenous immunization of Chang, Wang and Grayston<sup>15</sup> was used except that about one-quarter of the recommended dose of virus was given. Three-week-old mice received 1/8 of the amount of unpurified virus which killed 50 per cent of the mice when inoculated intravenously (MLD<sub>50</sub>), followed one week later by 1/3 MLD<sub>50</sub>. After a further 7 days, normal and immunized mice were challenged by either the intravenous or intranasal route with an inoculum expected to kill 80-100 per cent of 5-week-old mice. Table 1 shows the results of two such experiments. Mice thus immunized with ASGHf were protected against intravenous and intranasal challenge with the homologous strain, and were cross-protected against challenge with SA2f given by either route.

In contrast with previous reports<sup>1,3</sup>, I find that the trachoma agent multiplies in the adult mouse lung, in which it can be titrated with reproducible results. This positive result, however, may have been due to the different anaesthetic or to the different strain of mice used. All trachoma strains tested, whether of the fast or slow killing type for the chick embryo, multiplied in the mouse lung.

The adult mouse lung thus provides a useful system for investigating immunity to infection—as distinct from immunity to toxic death—induced by these organisms. The cross-protection observed between ASGHf and SA2f appears to differ from the findings of Bell and Theobald<sup>14</sup>. However, both these strains maintained at the Lister Institute grow in HeLa cells, whereas those used by Bell and Theobald do not. This difference in property may have been due to a change in antigenic structure during passage, as suggested by Reeve and Taverne<sup>17</sup>. Preliminary observations of the absence of cross-protection in mice induced by a slow-killing parent strain and a quick-killing variant derived from it support this idea.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Photographs of Mars taken by Mariner IV

NINETEEN close-up pictures of Mars, showing details down to a few kilometres across, were recorded by *Mariner IV* before the cameras crossed the terminator into the night hemisphere. The first seven pictures are not rich in detail because the Sun was less than 30° from zenith and shadows were absent. Later pictures, taken under a lower Sun, show progressively more relief: what may be afternoon shadows occur even on the ninth frame, composed at a solar altitude of more than 50°.

Contrasts between the shadows and the brightly lit parts of the surface of Mars show that the planet is mountainous and packed with craters and ring-structures strikingly like those of the Moon. Some of the craters have well-developed central eminences: by analogy with the central peaks of lunar craters, they may be volcanoes. Both the central eminences and the walls of the Martian craters appear to slope at steeper angles than those of the Moon. Whereas the mean inner slope of the wall of a well-developed lunar ring structure is 20° or 30°, the corresponding slope on Mars seems to be at least 40°.

Ring structures ranging up to 170 km in diameter are apparent on the eleventh frame recorded by *Mariner IV*. The largest is remarkably similar to the same-sized lunar feature Lacus Mortis, which is probably a lava-flooded, fault-bounded graben structure. The martian ring has a dark floor with crateriform or scalloped edges and may also be a lava-flooded collapse structure.

At present, it is difficult to say whether the majority of the newly discovered craters are the result of impact or volcanism. However, the *Mariner IV* pictures suggest to me that Mars has a volcanic terrain. The pictures are scored by ridge and depression lineaments that are similar to those on the Moon<sup>1</sup>, and there is strong evidence<sup>2</sup> for the growth of the lunar lineaments by volcanic extrusion from fractures and faults. Evidently, Mars has a fracture system of its own, and the indurated ridges may best be explained on the volcanic hypothesis.

The canals drawn on the older maps of Mars are not evident on those *Mariner IV* frames that might have registered them, but I have found a correlation between the trends of the recently photographed martian lineaments and the directions of the mapped canals. A possible explanation is that, as some observers<sup>3</sup> thought previously, the linear canals appear to form under certain conditions of poor seeing by the (subjective) connexion of many discrete patches of dark material arranged linearly on the surface of Mars. The patches might be widely separated ring structures, or groups of craters, arranged in linear chains, with floors of low albedo like many of the large lunar rings. These isolated features might well avoid the particular point in a 'canal' traversed by *Mariner IV*; and, even if they did appear in a picture, one would not necessarily associate them with a canal extending beyond the bounds of the frame.

On the Moon, chains of craters of a given type bear a close relation to the less readily seen Moon-wide lineament system. As, therefore, Mars seems to present volcanic phenomena like the Moon's, it is surely not surprising to find that the lineaments in small patches of Martian surface have trends similar to those of the coarser, larger-scale, canals.

Though full photometric and colorimetric calibration will be necessary before the *Mariner IV* pictures can be interpreted with confidence, it is possible to propose tentatively that the craters are not necessarily impact phenomena, and that the canals are not continuous

markings as drawn on the older maps but may be indicative of fractures or faults that dissect the solid surface of Mars.

This work was supported by a research grant from the Department of Scientific and Industrial Research. I thank the U.S. Information Service for providing the photographs of Mars.

## Lunar Hot Spots

I suggest that the thermal anomalies found recently in infra-red lunar observations<sup>1,2</sup> could be due to lunar roughness on a centimetre scale rather than due to changes in the thermal composition of lunar rock or localized thermal sources. The idea of roughness of centimetre dimensions<sup>3</sup> has now been directly verified by radar reflexion measurements. In fact, some protagonists of the dust hypothesis now incorporate this type of roughness in their models of the lunar crust.

Infra-red measurements at 11μ of lunar surface temperatures which range from 90° K to 400° K correspond respectively to values of 14.8 and 3.3 for the parameter  $x = hv/kT$  so that throughout the lower part of the temperature range Wein's law:

$$F_1 = 2\pi hc^2 \nu^3 \exp(-hv/kT)$$

is a good approximation to the correct radiation law connecting the radiative energy density  $E_\nu$  from the lunar surface at frequency  $\nu$  with the temperature  $T$ . This result shows that lunar night-time and eclipse observations made through the 8-14μ atmospheric window are extremely sensitive to small temperature changes of the lunar surface. Because of the highly non-linear variation of  $E_\nu$  with  $T$  the brightness temperature, measured by an instrument which sees simultaneously a number of surfaces, will be considerably higher than the mean temperature especially if the surfaces have widely differing temperatures.

Using the model previously proposed<sup>3</sup> and shown in Fig. 1, I have calculated from approximate heat flow considerations the temperatures  $T_1$  and  $T_2$  at the middle of an eclipse in the case for which a smooth surface composed of the same material would give a temperature of 200° K. Values of  $T_1 = 275^\circ$  K and  $T_2 = 195^\circ$  K are obtained from the calculation and these give a brightness temperature of 240° K for telescope observations at zero lunar zenith angle. An increase in the radiative density by a factor of nearly 3 is thus expected when rough and smooth regions are compared during an eclipse. The existence of preferential roughness of centimetre dimensions should thus show up clearly in scans across the lunar disk during an eclipse. It is interesting that the eclipse measurements recently made by Shorthill and Saari<sup>1</sup> show regions of radiation enhancement both greater and less than that calculated from this simple model.

Fig. 1

In the case of hot spots which coincide with craters it is very unlikely that the spots can be attributed to local heat sources since these craters have been shown to be cooler than the surroundings during the lunar day<sup>4</sup>. The case of the crater Tycho is particularly interesting since radar reflexion results<sup>5</sup> give strong back reflexion (indicating a rough or a more dense surface) while the infra-red eclipse measurements show this crater to be a very intense hot-spot. More generally, the spots are found to be associated with maria as well as crater centres<sup>1</sup>. The present hypothesis therefore requires that these regions have preferential roughness. Such an explanation is in good agreement with visual results. It is well known that the albedo for crater centres and maria is in general lower than that for lunar highland while rougher surfaces have in general a lower albedo than smooth ones.

I thank Dr. G. Fielder of the University of London Observatory for his advice.

## PHYSICS

### Lattice Constants of Gallium at 297° K

THE  $a$  and  $b$  lattice constants of gallium (orthorhombic,  $D_{2h}^{18}$ - $Abma$ ) are almost identical and have often been a source of confusion, as has recently been emphasized by Yaqub and Cochran<sup>1</sup>. Diffractometer data at 4.2° K (ref. 2) (gallium of 99.9999 per cent grade) indicated  $a = 4.5156$  Å,  $b = 4.4904$  Å,  $c = 7.6328$  Å, but at 297° K it appeared that  $a$  is smaller than  $b$  (in disagreement with Bradley<sup>3</sup>), and therefore that at an intermediate temperature (near 255° K)  $a$  should become equal to  $b$ .

An experimental investigation of mechanical twinning at different temperatures, involving compressive and tensile stressing, proved that twins could be produced by compression along  $a$  and tension along  $b$ <sup>4,5</sup>, whereas neither tension along  $a$  nor compression along  $b$  produced twinning, a result interpreted to imply that  $a$  is greater than  $b$  at 297° K, and bringing the 1961 conclusion into question. Furthermore, it was found that tensile stressing along  $a$  at 255° K produced no twins, whereas if  $a = b$  at this temperature, twinning would be expected<sup>4</sup> on the basis that the occurrence of twinning is associated with the elastic anisotropy ( $S_{33} > S_{11}$ ).

The 1961 conclusion for 297° K was independently brought into question by Cochran<sup>6</sup>, who noted that the expansion coefficients for  $a$  and  $b$  were in disagreement with Powell's<sup>7</sup> and could be brought into better agreement if the 4.2° K results of 1961 were accepted but if  $a$  were assumed to be greater than  $b$  at room temperature as well as at 4.2° K.

The 297° K powder diffraction data of 1961 have now been re-computed using new indices for the reflexions, corresponding to  $a > b$ , bringing the calculated value ( $\theta_{204} - \theta_{111}$ ) much closer to the observed value of this significant angle. The new indexing leads to least squares solutions (either with various extrapolation factors or without corrections) that invariably give better overall agreement between calculated and observed  $\theta$  values than the 1961 indexing. The Vogel-Kempter and the Nelson-Riley extrapolation functions both yielded the following results:

	$a$ (Å)	$b$ (Å)	$c$ (Å)
Re-computed values	$4.5258 \pm 0.0007$	$4.5186 \pm 0.0007$	$7.6570 \pm 0.0012$
Bradley (ref. 3)	4.5258	4.5196	7.6602

The agreement with Bradley's values (converted by the factor 1.00202) is much improved. The results now do not conflict with the anisotropic expansion coefficients of Powell<sup>7</sup>, assuming that the  $\theta$ -values of 1961 at 4.2° K are correctly indexed, which we have no reason to question. We therefore conclude that the 1961 values at 297° K should be replaced by the foregoing, that the interpolated values of 1961 for 78° K should be discarded, that  $a > b$  throughout the temperature range, and that the anisotropic thermal expansion is such that  $\Delta b/b > \Delta a/a$ .

## GEOPHYSICS

### Linear Relationship between Energy and Pressure of Volcanic Explosions

EARLY investigations on the velocity of bombs and the gas pressure of single volcanic explosions by Matuzawa<sup>1-3</sup> led to a means of determining gas pressures which have been generally accepted and used by volcanologists. Matuzawa stated<sup>1</sup> that the initial discharge velocity of volcanic explosions depended primarily on the gas pressure, which could be calculated from the dynamic pressure relationship of Bernoulli's equation:

$$P = \frac{1}{2} \rho v^2$$

where the gas pressure,  $P$ , represents the pressure difference between the interior and exterior of the vent,  $\rho$  is the density of the mass of fragments plugging the vent, and  $v$  is the discharge velocity of volcanic bombs.

Results of investigations by Minakami<sup>4</sup> led to the determination of the amount of kinetic energy necessary to impart the initial velocity to volcanic ejecta (bombs):

$$E = \frac{1}{2} m v^2$$

where  $E$  is the kinetic energy,  $m$  is the mass of ejecta, and  $v$  is the velocity of ejecta at the instant of ejection.

Fig. 1. Relation of the logarithm of kinetic energy of volcanic explosions to the logarithm of the gas pressure at the time of the explosion.

Minakami calculated the energies and pressures for a number of eruptions of Asama Volcano in Japan<sup>4</sup>.

On March 30, 1956, a paroxysmal explosion of Bezymianny Volcano, Kamchatka, occurred. Gorshkov<sup>5</sup> determined the energy of this eruption from the seismic energy connected with the explosion, from the air wave of the blast, and from the equation here, each of which gave approximately the same value. Gas pressure at the time of the explosion was computed from Bernoulli's equation. Values were appreciably higher than for the Asama eruptions and it appeared that a relationship between energy and pressure might be found based on the Japanese and Russian data.

Values published by Minakami and Gorshkov are plotted in Fig. 1, in which is shown an eye-fitted linear relationship between the logarithm of kinetic energy and the logarithm of gas pressure. The equation of the relationship is:

$$E = 10^6 P^{1.2}$$

where energy is in ergs and pressure is in atmospheres or in bars.

Data used in Fig. 1 are few in number, and it would be very desirable for volcanologists to augment them to learn if the given relationship is valid throughout the range of pressures and energies associated with volcanic eruptions. While there are a number of reports on the energies of explosions, for example refs. 6 and 7, and the energy may be determined from barograms<sup>8</sup>, the necessary observations needed to calculate pressures are lacking. It is hoped that this deficiency will soon be rectified.

This work was carried out in 1961 while I held a National Academy of Sciences—National Research Council postdoctoral resident research associateship at the U.S. Navy Electronics Laboratory in San Diego, California.

## GEOLOGY

### Origin of Australites

THE problem of the origin of tektites, of australites in particular, has been a subject of speculation and controversy for many years. A great body of physical and chemical data on tektites is available and has been used to support various genetic arguments.

According to their present-day terrestrial manner of occurrence, tektites are geological material. Consequently, all their geological properties must be investigated. Physical and chemical data are not sufficient.

During my stay in Australia, I have been fortunate enough to examine the principal public and private australite collections. My investigation was undertaken in order to check the lithological homogeneity of australites, with particular reference to the presence of inclusions of material 'foreign' to them. The number of specimens which I examined totals more than 33,000 (see Table 1). The specimens were initially investigated by means of a 10-power magnifying glass. Any specimens suspected of containing 'foreign' material were put aside and eventually borrowed to be submitted to microscopic investigation. Thin sections were prepared and investigated of several specimens, but 'fingers' were the only internal feature observed.

All the specimens available were checked. Thus, the material investigated consisted of fresh well-preserved

Table 1. SOURCES AND NUMBERS OF LITHOLOGICALLY INVESTIGATED AUSTRALITE SPECIMENS

Source of material	No. of samples investigated
Australian Museum, Sydney	308
South Australian Museum, Adelaide	19,308
National Museum of Victoria, Melbourne	1,621
Western Australian Museum, Perth	1,696
University of Adelaide, Department of Geology and Mineralogy	1,812
University of Melbourne, Department of Geology and Mineralogy	623
University of Queensland, Department of Geology and Mineralogy	248
School of Mines of Western Australia, Kalgoorlie	196
Dr. George Baker, Melbourne, Vic., private collection	2,958
Mr. W. H. Cleverly, Kalgoorlie, W.A., private collection	241
Mr. Dale Tillotson, Kalgoorlie, W.A., private collection	4,227
Mr. C. B. O. Jones and Mr. John Jones, Hampton Hill Station, Kalgoorlie, W.A., private collection	70
Other sources (including Geological Survey, Hobart; Museum, Hobart; University of Western Australia; Queensland Museum)	197
Total	33,696

The australite collection in the South Australian Museum is the largest public collection in existence. Mr. Tillotson's collection, in June, 1965, totalled about 5,300 specimens. The two collections could not be examined in toto, because many samples were being investigated by research workers in the United States. The Jones collection, derived mainly from the Hampton Hill Station area, according to a conservative estimate of the owners, totals about 10,500 specimens but may amount to 11,000 specimens. The 70 specimens investigated were selected at random.

specimens and water- and wind-worn corroded and abraded specimens, whole specimens and fragments, and large and small australites.

During the course of the investigation I was unable to find any material foreign to australites even in a single specimen. Lithologically, the material was exceedingly homogeneous, even to the extent of being monotonous. I was particularly keen on trying to find inclusions of terrestrial sedimentary and igneous rocks, such as shale, sandstone and granite which, because of similarities in chemical composition, are believed by many to be the parent material of tektites; but all my efforts were in vain. Moreover, the museum curators and the owners of private collections assured me that they had never observed any 'foreign' material in australites. Consequently, adding to the 33,700-odd australites which I personally investigated another 1,000 specimens from the Tillotson collection (see Table 1) and the 10,500-odd specimens in the Jones collection (see Table 1), the conclusion follows that no 'foreign' material whatsoever has been observed in a total of about 45,200 australites. This sample certainly represents the majority of australites so far discovered, and the statistical probability of finding inclusions of terrestrial material in any other australite is extremely small. Finally, Chao<sup>9</sup> examined about 2,000 australites under the binocular microscope; his report does not mention the presence of 'foreign' matter in this material.

If the australites originated by an asteroid impact, a giant meteorite impact, or a comet impact on the Earth, as Urey<sup>3</sup>, Barnes<sup>1</sup> and Cohen<sup>4</sup>, among others, have suggested, then they, like genuine impactites<sup>10</sup>, would be heterogeneous. I find it impossible to believe, on the basis of my lithological observations, that australites are terrestrial impactites. Their lithological homogeneity rules out terrestrial origin. The impact producing such a homogeneous material would certainly have been so violent and of such dimensions that several generations of trained geologists could not possibly have failed to observe other effects caused by such a tremendous catastrophe.

If australites formed by an impact on the Moon, their lithological properties suggest that the part of the Moon's surface in which they originated must have been very homogeneous indeed.

## Upper Cretaceous Fossil Molluscs In South America and West Africa

OVER the past few years there has been a great revival of interest in the theory of continental drift, owing largely to the results yielded by palaeomagnetic investigations. Whereas most geologists a decade ago were inclined to be sceptical about the possibility of the continental land masses having wandered, the evidence now available appears much more convincing.

The close relationships in the floras and in the reptile associations of the Gondwanic continents have long been one of the mainstays of the hypothesis of the existence of Gondwanaland. It seems, however, that little attention has been paid to eventual biological similarities of a later age. The object of this communication is to present observations on some mollusc species that occur in the Upper Cretaceous of the northern half of South America and in Nigeria and Cameroon. Knowledge of (particularly South American) Cretaceous molluscs is still not very advanced and it might reasonably be expected that more common species will show up in the future, for example, when the vasocoeratiid associations of Brazil are investigated.

Table 1 lists the species known to occur in both regions (see also ref. 1).

Table 1. OCCURRENCE OF WEST AFRICAN MOLLUSCS IN SOUTH AMERICA

Species	Age	Occurrence
<i>Pachyaecoceras costatum</i> Reymont (ammonite)	Turonian	Peru, Eastern and Northern Nigeria
<i>Hoplitoides ingens</i> (von Koenen) (ammonite)	Turonian	Colombia, Cameroon, Northern Nigeria, Eastern Nigeria
<i>Benuosites benuosensis</i> Reymont (ammonite)	Turonian	Brazil, Colombia, Northern Nigeria
<i>Benuosites spinosus</i> Reymont (ammonite)	Turonian	Trinidad, Peru, Colombia, Northern Nigeria
<i>Solgerites brancoi</i> (Solger) (ammonite)	Coniacian	Cameroon, Colombia, Peru
<i>Lima pseudohornesi</i> Riedel (pelecypod)	Turonian	Peru, Cameroun, Gabon, Northern Nigeria

The interest in connexion with the geographical distribution of these molluscs lies in the problem of their dispersal which, for the ammonites, has to be viewed in the light of their neoplanktonic buoyancy properties (cf. Reymont<sup>2</sup>), and consequently with respect to oceanic currents.

*Pachyaecoceras costatum* Reymont has a moderately inflated and slightly evolute shell, approximating in form to *Nautilus*. There is little doubt that it, like the living *Nautilus*, could have been posthumously transported by ocean currents over considerable distances.

*Hoplitoides ingens* (von Koenen) has an involute, fairly strongly compressed shell of a shape bordering on that of the type considered by me<sup>3</sup> to have been unable to remain buoyant after the death of the animal, unless the body chamber has been largely broken off. Both the species of *Benuosites* have small involute to slightly evolute and fairly compressed shells with thin walls, and may not have been capable of wide neoplanktonic dispersal.

*Solgerites brancoi* Solger has a round whorl section and is slightly evolute and had certainly good neoplanktonic floating properties. It should finally be mentioned that all these ammonites are "typical West African forms" and, apart from a doubtful report of *H. ingens* from North Africa, seem only to have been found in the northern part of South America, outside West Africa.

To sum up, it seems that only two of the five ammonite species might have survived dispersal across an Atlantic Ocean of the width of the present day, assuming favourable currents existed. The case of *Lima pseudohornesi* Riedel is even more difficult to explain, for if the mechanics of the dispersal of the ammonite shells poses problems, that of a benthonic pelecypod species is very much greater. We have the fact that most of the known occurrences of these species are on 'the wrong side' of South America, but there may have been a shallow sea in existence in northern South America at that time.

Although it is far too early to make anything even approaching a positive statement on the subject, and although this will not be possible until much more published taxonomic information becomes available from South America, it seems that these molluscan distributions might offer some support for the palaeomagnetic results obtained by Creer<sup>4</sup>, Runcorn<sup>5</sup> and others. Their work suggests that Brazil and Nigeria of to-day mark the point of contact of the continents in the Upper Palaeozoic (and thus supports the finding made by fitting coastlines and Pre-Cambrian tectonics<sup>6</sup> and that the rift took place during Upper Permian<sup>7</sup> and widened during the Mesozoic<sup>8</sup>.

Although there is marine Devonian known in Ghana, the first dated marine transgression for the critical central area is the Upper Middle Albian incursion in Nigeria. Older Cretaceous occurs some distance north and south of Nigeria, but there is no marine Jurassic. This might be interpreted as evidence that the two continents were still very close together during early Cretaceous time. The existence of a narrow sea during the Upper Cretaceous, similar to the Red Sea of to-day, would go a long way towards explaining the distribution of the Upper Cretaceous molluscs here discussed.

## CHEMISTRY

### Octahedral Metal Clusters

THE bonding in the  $\text{Mo}_6\text{Cl}_8^{4+}$  and  $\text{Ta}_6\text{Cl}_8^{3+}$  cations, both of which contain an octahedron of metal atoms, has recently been rationalized in terms of a 40-electron model<sup>1</sup>. The edges of the metal octahedron define the orientation of twelve bonds (type A) while the faces of the octahedron define the position of another eight (type B). In  $\text{Mo}_6\text{Cl}_8^{4+}$  twenty-four metal electrons fill the A orbitals and sixteen chlorine  $\sigma$  electrons fill type B. In  $\text{Ta}_6\text{Cl}_8^{3+}$  the roles of the sixteen metal and twenty-four chlorine  $\sigma$  electrons are interchanged. It is now possible to speculate on the occurrence of other metal octahedra if we require that this 40-electron rule be obeyed.

There are two other possible atomic arrangements with  $O_h$  symmetry. These are: (a) that in which there are ligands above both faces and edges of the metal octahedron; (b) that in which there are no ligands at all. We consider these separately. A possible molecule of type (a) is  $(\text{Al}_6\text{Cl}_{18})^{3-}$  in which both A and B bonding orbitals are filled by chlorine  $\sigma$  electrons. There should be no specific metal-metal bonding and a consideration of ionic radii makes it evident that there would be considerable steric interaction between the chlorine ions. It therefore seems most unlikely that such molecules exist.

If orbitals of types A and B are filled by metal electrons then no ligand need be incorporated (type (b)). There would be no de-stabilizing steric interactions, and if the charge on the octahedron were small it seems highly probable that the species would be stable. The molecule  $\text{Re}_6\text{I}_8$  (actually  $\text{Re}_6^{3+}2\text{I}^-$ ) satisfies these conditions. The iodide anion is suggested since it is large and singly charged; there are many plausible alternatives. Although no such species has been found in the manganese- or rhenium-iodine systems, it is possible that reactions in which the metal appears to have been produced (for example, thermal decomposition of  $\text{Mn}(\text{CO})_5\text{I}$ ) may, in fact, have led to their formation. The 'isoelectronic'

species  $Ru_3I_8$ ,  $Os_3I_8$ ,  $Rh_3I_8$ , and  $Ir_3I_8$  are also potentially examples. The rhodium chloride ' $RhCl_3$ ' reported by Wöhler and Müller<sup>2</sup> might contain a metal octahedron. The chlorine analyses obtained (44.6; 44.0 per cent) agree much more closely with that required for  $Rh_3Cl_{14}$  (44.6 per cent) than with that required for  $RhCl_3$  (40.8 per cent). It should be noted that this formulation gives the cation an improbably large charge, although this could perhaps be offset by a weak co-ordination of the chloride anions.

## Existence of Half-salt Cations in Aqueous Solutions of Aminophenols

INTEREST in the properties of aminophenols as bifunctional organic substrates in aromatic substitution prompted us to re-investigate the acid-base dissociation constants of these compounds. The method chosen was the measurement of pH in acid-base titrations of sample solutions under a nitrogen atmosphere.

Aminophenols were shown to be ampholytes with no zwitterion structure<sup>1</sup>, and therefore the following two dissociation stages can be distinguished *a priori* in their aqueous solutions:

where  $B$  represents a neutral aminophenol molecule,  $B^+$  the ammonium cation and  $B^-$  the phenolate anion. (It is customary to represent equilibrium (1) inverted; however, all the equilibria are shown and calculated as acid dissociations of the species on the left side, in order to preserve uniformity.) Dissociations (1) and (2) can be measured by titration of neutral aminophenol solutions with hydrochloric acid and sodium hydroxide solutions respectively.

The titrations with sodium hydroxide behaved normally in the sense that the experimental curve of pH versus added volume of reagent solution corresponded to the curves calculated by assuming a certain  $pK_1$  value, as shown in Fig. 1.

Such was not the case when the organic substrate was titrated with acid solution. Fig. 2 shows an experimental titration curve of *p*-aminophenol with 0.1 N hydrochloric acid, which is compared with curves calculated for three different values of  $pK_1$ .

The location of the stoichiometric equivalence point in Fig. 2 is noteworthy, as it lies about one-third in excess of the volume necessary to attain the inflexion point. The

Fig. 1. Titration of 50 ml. of 0.01443 M aqueous *p*-aminophenol with 0.1 N sodium hydroxide, at 40° C (—, calculated; O, experimental)

Fig. 2. Titration of 50 ml. of 0.03939 M aqueous *p*-aminophenol with 0.1 N hydrochloric acid, at 40° C (—, calculated; O, experimental)

same occurs in the cases of *o*- and *m*-aminophenol, but to a lesser degree. This abnormality is also evident in the very great discrepancy between the values of columns V and VI in Table 1. If the only important equilibrium in acidic solutions is equilibrium (1), columns V and VI should be equal, as they represent  $pK_1$  values calculated at two stages of neutralization during titrations with hydrochloric acid.

Table 1. EQUILIBRIUM CONSTANTS FOR THE DISSOCIATION OF *p*-AMINOPHENOL ( $B$ ) IN AQUEOUS SOLUTION AT 30° (TITRATION WITH HYDROCHLORIC ACID)

$10^4 [B]$	I	II	III	IV	V	VI
0.733	4.875	3.43	4.62	10.77	4.88	3.34
1.072	5.006	3.306	4.71	10.32	5.00	3.55
1.445	4.97	3.23	4.71	10.41	4.97	3.37
2.144	4.97	3.15	4.78	10.32	4.97	3.32
2.961	4.875	2.975	4.46	10.78	4.88	3.03
4.258	5.04	2.94	4.95	10.32	5.04	3.14
5.733	4.97	2.705	5.07	10.68	4.97	2.91
8.577	5.11	2.52	5.05	10.31	5.11	2.73
11.564	5.25	2.38	5.19	11.01	5.25	2.55
17.154	5.006	2.24	4.93	10.42	5.00	2.48
23.123	5.006	2.10	4.82	10.58	5.00	2.32
33.238	5.04	1.96	4.97	11.06	5.04	2.06

Explanation of the columns: (I) pH at half stoichiometric neutralization; (II) pH at stoichiometric neutralization; (III)  $pK_1$ , assuming equilibria (1) and (2); (IV)  $pK_1$ ; (V)  $pK_1$ , calculated for the points in column I assuming equilibrium (1) alone; (VI)  $pK_1$ , calculated for the points in column II assuming equilibrium (1) alone.

In order to account for the observed irregularities an equilibrium (3) is postulated, in which a complex  $B_1^+$  is formed by association of a cation  $B^+$  with one neutral molecule  $B$  as follows:

Qualitatively such type of equilibrium explains the observed "excess of protons" during the titration—in Fig. 2 the excess is shown by the experimental pH being lower than those of the calculated curves—because we have in fact less free base  $B$  than we should have according to equilibrium (1) alone.

Indeed, from the pH values found in experiments in which the initial concentration of *p*-aminophenol was varied over a forty-fold range (columns I and II of Table 1),  $pK_1$  and  $pK_2$  values were calculated. The results are shown in columns III and IV of Table 1, and give an average of  $4.86 \pm 0.20$  for  $pK_1$  and  $10.60 \pm 0.25$  for  $pK_2$ .

These 'manual' calculations could not be successfully applied to the other bases studied, as the equations become unacceptable owing to the lower deviations from an ordinary titration observed in these cases; therefore more

sophisticated numerical methods involving electronic computers would be required.

It is interesting to notice that the  $pK_1$ 's in column III and column V of Table 1 do not differ very much, which suggests that equilibrium (3) becomes extremely important for the stoichiometric balance of the system mainly towards the final stages of the titration, where the largest deviations occur. We believe that other investigators failed to notice these association phenomena for several reasons: determinations of  $pK_1$  were made in mixtures where association passes unnoticed, for example, using equimolecular mixtures of the free base and the hydrochloride<sup>3</sup>, whereas we have already seen (columns III and V of Table 1) that the deviations are not large; or using low pH buffer solutions<sup>4</sup>, where the associated cation  $B^+$  probably undergoes nearly complete dissociation into two ammonium cations  $B^+$ ; another possible reason is the use of ultra-violet spectroscopy<sup>3,4</sup> which might be inadequate for the observation of the associated species. It is possible, therefore, that these types of associated ions in solution were overlooked in many other cases.

### Identification of Disulphur Monoxide as an Absorbing Species in Carbonyl Sulphide Discharge Products

In a recent article<sup>1</sup> an absorption spectrum in the 2650–3250 Å region, obtained from the products of an electrical discharge through carbonyl sulphide vapour, was described. The carrier of this spectrum was tentatively identified as  $C_2S_2O$ , an analogue of carbon suboxide. This same absorption spectrum was also observed after the flash photolysis of carbonyl sulphide.

It would appear from chemical arguments that  $C_2S_2O$  would not be a likely product of the near-ultra-violet photolysis of COS, since photolysis would yield CO and some CS, both of which are quite resistant to further photolysis. Unless free carbon is formed, it is difficult to find a reasonable mechanism for the formation of 3-carbon chains during flash photolysis. Since free carbon was detected<sup>1</sup> during the electrical discharge through COS, a 3-carbon chain could form under these conditions, although high-energy discharges seem to favour the production of the simpler and more stable molecules<sup>2,3</sup>.

We have now convincingly identified this spectrum as belonging to disulphur monoxide, first prepared by Schenk in 1933 (ref. 4) but identified by him as  $SO$ . Schenk's compound was later ascribed to  $S_2$  by Cordes<sup>5</sup> and to  $S_2O_2$  by Jones<sup>6</sup>. Recently, mass spectrometry<sup>7</sup> and microwave spectroscopy<sup>8</sup> have definitely identified Schenk's compound as the bent molecule,  $SSO$ . The band heads and rough intensities reported by Cordes<sup>5</sup> are in good agreement with the COS discharge product spectrum, as are the long wave-length band heads at 3193 Å and 3234 Å observed by Jones<sup>6</sup>.

Authentic  $S_2O_2$  was prepared by the method of Jones<sup>6</sup>, and a 750-joule discharge through 10-torr COS was used to produce the discharge product. A 180-cm path-length through the gas at about 1 torr was used in obtaining the absorption spectra. High resolution spectra of both  $S_2O_2$  and the COS discharge product were obtained in the

3190–3296 Å region, and several  $S_2O_2$  bands were identified in both samples. Direct comparison of the fine structure in the 3234 Å band shows that the COS discharge product is  $S_2O_2$ . Several shorter wave-length bands, most notably the strong 2907 Å band, were seen in the discharge product, but these were masked by the excess  $SO_2$  absorption when the  $S_2O_2$  sample was used. The products of a Tesla coil discharge in flowing COS also gave the same  $S_2O_2$  absorption spectrum. Since  $S_2O_2$  is known to be a very strong absorber<sup>9</sup>, it may be only a minor product of the discharge.

The mass spectrum of the COS discharge products contains a small mass 80 peak corresponding to  $S_2O_2$ , but no peak at mass 84 which would correspond to  $C_2S_2O$ . The mass 80 peak was mainly  $S_2O_2$ , not  $SO_2$ , since the mass 82 peak due to  $^{34}S$  was about 8.2 per cent of the mass 80 peak, or nearly twice the 4.2 per cent natural abundance of  $^{34}S$ . Mass spectrometry of the  $S_2O_2$  sample gave the same mass 80 and 82 peaks.

No investigation was made of the lifetime of the discharge product, but the mass 80 peak was still present the day after the preparation of the discharge product.

The  $S_2O_2$  absorption spectrum was seen by Wright<sup>10</sup> during the flash photolysis of  $CS_2$  in the presence of  $O_2$  or  $SO_2$ . It is thus not unreasonable to expect some  $S_2O_2$  during the flash photolysis or electrical discharge of COS.

I thank B. J. Killoran for his assistance. Dr. E. D. Loughran did the mass spectrometry. I also thank Drs. N. R. Greiner and P. E. Rouse, jun., for their advice.

### Oxidase-like Activity of the Copper (II) Poly-L-histidine Complex

SYNTHETIC polyamino-acids have been shown to be instructive protein models<sup>1</sup>. It seems reasonable to assume that their combination with metal ions exhibits some resemblance to metalloproteins. This possibility was investigated by examining the catalytic activity of complexes of copper with polyamino-acids.

Copper-ion-catalysed oxidations of ascorbic acid and quinols by molecular oxygen have been previously suggested as models for copper containing oxidases<sup>2</sup>. This catalytic activity of copper ions is substantially dependent on the nature of the ligands<sup>3,4</sup>. Certain ligands were found to induce an increase in the catalytic activity of copper. On the other hand, certain polydentate ligands like ethylenediamine and ethylenediamine tetraacetic acid were found to act as inhibitors. A similar effect is exhibited by the non-specific binding of  $Cu^{2+}$  by protein molecules such as bovine serum albumin<sup>5</sup>.

The oxidation of ascorbic acid and *p*-hydroquinone by molecular oxygen, catalysed by different complexes of copper (II) with amino- and polyamino-acids, has been investigated. It was shown (Table 1) that histidylhistidine and polyhistidine are the only complexing agents which markedly increase the catalytic efficiency of the copper induced ascorbic acid oxidation. The other amino- and polyamino-acids examined were found to have no positive effect on the activity of copper under the same conditions. Moreover, an inhibitory effect of the complexants was

Table 1. EFFECT OF LIGANDS ON THE CUPRIC-ION-CATALYZED AUTO-OXIDATION OF ASCORBIC ACID

The reaction mixture contained  $6 \times 10^{-4}$  M  $\text{CuSO}_4$ ,  $1.5 \times 10^{-4}$  M ascorbic acid and the complexing agent at the specified concentration in 0.02 M sodium acetate buffer pH 4.0. The reaction mixture was saturated with pure oxygen before adding the substrate solution. Initial rates of ascorbate oxidation at room temperature were followed spectrophotometrically at 265 m $\mu$  on a Zeiss PMQ-II spectrophotometer. All polyamino-acids were supplied by YEDA Research and Development Co., Rehovoth, Israel.

\* molecular weight 10,000  
† " " 75,000  
‡ " " 15,400

encountered in some cases. The kinetic pattern of the copper-polyhistidine catalyzed reaction is substantially different from that of the aquo and acetato complexes. A typical Michaelis-Menten kinetic dependence is demonstrated by the polyhistidine complex with an apparent  $K_m = 1.5 \times 10^{-4}$  M, whereas the kinetics of the aquo-complexes-induced oxidation is first order in ascorbic acid within the range  $10^{-4}$ – $10^{-5}$  M. The value of  $K_m$  is of the same order of magnitude as that obtained for the ceruloplasmin catalyzed reaction<sup>4</sup>. A remarkable difference in the pH dependence between the copper-polyhistidine- and the aquo-complex-catalyzed auto-oxidation was also observed. The ratio of the rates of the two catalytic systems reaches a maximum at pH 4.1, whereas at higher or lower pH values this ratio decreases, reaching a value of unity at pH = 3.3 and 5.8.

At a constant polyhistidine concentration the catalytic efficiency of the copper-polyhistidine complex increases with the amount of copper added to the system, reaching a maximum value corresponding to one copper ion per two histidyl residues.  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$  and  $\text{Mn}^{2+}$  ions were also examined in the presence of the aforementioned amino- and polyamino-acids and were found to be without catalytic effect on ascorbic acid oxidation.

The copper-polyhistidine catalyzed oxidation of *p*-hydroquinone exhibits even more conspicuously the unique behaviour of this macromolecular copper complex. This complex induces a rapid oxidation of the hydroquinone within the pH range 3.5–5.5. At pH 4.5,  $[\text{Cu}^{2+}] = 5 \times 10^{-4}$  and  $[\text{polyhistidine}] = 1 \times 10^{-3}$  M the rate of hydroquinone oxidation was  $8 \times 10^{-7}$  moles/l./min. The catalytic activity of the aquo- or acetato-complexes of cupric ions as well as any of the other complexes listed in Table 1 is smaller by more than two orders of magnitude. Under identical experimental conditions catechol was not susceptible to oxidation by either copper (II) or its polyhistidine complex. The kinetics of *p*-hydroquinone oxidation were followed spectrophotometrically at 240 m $\mu$  as well as manometrically by recording the rate of oxygen consumption. At low hydroquinone concentrations, the kinetic behaviour was found to be similar to that of ascorbic acid oxidation. The apparent Michaelis-Menten constant for this reaction was found to be  $3.5 \times 10^{-3}$  M.

The generally accepted mechanism<sup>5,6</sup> for the cupric-ion-catalyzed auto-oxidation proceeds schematically through the following steps:

followed by

or

Where  $\text{H}_2\text{A}$  stands for the reductant and  $\text{HA}^\cdot$  is the free radical formed by single electron oxidation. In the copper-polyhistidine-catalyzed reaction the only oxidation products of ascorbic acid and *p*-hydroquinone were shown to be dehydroascorbic acid and *p*-benzoquinone respectively. Hydrogen peroxide was the product of the reduction of oxygen and its yield corresponds to the amount of the absorbed oxygen and to that of the oxidized substrate. This suggests that the reaction catalyzed by the copper-polyhistidine complex follows a similar chemical route to that by the cupric ion.

The interpretation of the efficiency of the copper polyhistidine system deserves a thorough investigation. At the present stage we can only make a few comments on the observed phenomena. The binding of copper ions by the imidazole groups of the polyhistidine increases the redox potential of the  $\text{Cu}^{\text{I}}-\text{Cu}^{\text{II}}$  couple by the stabilization of monovalent copper<sup>7</sup>. This alone cannot account for the observed facts since imidazole, histidine and even histidylhistidine do not exhibit catalytic effect to the same degree. The Michaelis-Menten kinetic behaviour observed in the  $\text{Cu}(\text{II})$ -polyhistidine-catalyzed oxidation indicates the formation of a complex between the catalyst and the substrate. The factors favouring the formation of such a complex are likely to be of electrostatic nature, and since the  $\text{Cu}(\text{II})$  polyhistidine complex is positively charged due to the protonated imidazole nitrogens, it should be pH-dependent. Binding of the substrate to the positively charged macromolecule by an electrostatic interaction results in the formation of  $\text{HA}^\cdot$  bound to the  $\text{Cu}^{\text{II}}$ -polyhistidine complex. As  $\text{HA}^\cdot$  is more readily oxidized than  $\text{H}_2\text{A}^\cdot$ , this could possibly account for the enhanced catalytic activity of the polyhistidine complex.

### Dissolved Silicate and Particulate Iron Content in Different Water Types

CONSIDERABLE information regarding the complex circulation pattern which exists in the waters surrounding the Hawaiian island chain has been obtained through the analysis of surface waters at a station near Koko Head on the Island of Oahu which has been monitored by the U.S. Bureau of Commercial Fisheries since 1956. Temperature and salinity data, together with information gathered in six oceanographic surveys made since 1949 in the vicinity of the high islands of the Hawaiian archipelago, have shown that the islands are surrounded by the cooler and more saline water of the Western North Pacific in winter and by the warmer and intermediate salinity water of the California Current Extension in the summer<sup>1</sup>. The boundary between these two layers of water as shown by a relatively high salinity gradient moves north and south through the island chain and is responsible for the seasonal variations in water type. The Hawaiian waters, being subtropical in nature, are not normally subject to appreciable

Fig. 1. Silicate-salinity relationship, March 1961-February 1962, at the Koko Head monitoring station, Oahu, Hawaii

changes in standing crops of phytoplankton. Consequently, it seemed of interest to investigate the possibility that variations in trace metals and other chemical species might reflect changes in water type.

Analysis of dissolved silicate and particulate iron was carried out on a weekly basis on surface water samples collected at the Koko Head station from March 1961 through April 1962. The monthly mean concentration of silicate-Si ranged from 0.49 to 1.81  $\mu\text{g-atom/l.}$  and that of particulate iron from 0.50 to 3.44  $\mu\text{g-atom/l.}$

Although seasonal variations of both silicate and particulate iron were discernible, it was not possible to relate these to known local biological activity in the waters. A plot, however, of the monthly mean values of silicate versus the corresponding monthly salinities reveals three distinct distribution groups (Fig. 1). With the studies of Seckel and others<sup>1</sup> on the surface water types of the Hawaiian islands in mind, it can be assumed that the water types moving in and out of the island chain have varying silicon and iron content and that the groups in Fig. 1 indeed represent these different water types. The biological history of each water type is undoubtedly different and hence is responsible for the variation in silicon and particulate iron content. Similar characteristic distribution groups were also observed with particulate iron. Inorganic phosphate and nitrate did not show such distinct groups but rather indicated annual cycles<sup>2</sup>. It is not known whether data on other trace metals will reveal information similar to that obtained from silicate and particulate iron. However, if such proves to be the case, trace element content could be used advantageously under the proper conditions as an additional tracer for distinguishing water types.

We are indebted to the Bureau of Commercial Fisheries (Honolulu) for making available salinity data obtained at the Koko Head monitoring station.

### Thin-layer Chromatography in S-tanks of Mixtures containing Free Fatty Acids

FREE fatty acids may be readily separated from other lipids by chromatography on thin layers of silica gel. The solvents used generally contain a small amount of acetic acid<sup>1-4</sup> the purpose of which is to suppress dissociation of the fatty acids being chromatographed and thereby prevent serious 'tailing' of the spots.

Stahl<sup>5</sup> has described the separation of phenolic acids with an acid-free developing solvent on silica gel containing a small amount of oxalic acid. Experiments in this laboratory have shown that mixtures containing free fatty

Tristearin	0.93

Adsorbent: Silica gel G (Merck) + 2% w/w oxalic acid. Humidity: circa 55%. 20° C. Solvent: 1:1 cyclohexane: di-iso-propyl ether (purified over alumina, grade 1). 15 cm development. Detection by charring was not affected by the oxalic acid.

acids may also be chromatographed with an acid-free solvent in ordinary rectangular tanks, provided that there is some acetic vapour in the atmosphere of the tank. Presumably this vapour is rapidly absorbed by the dry layer and behaves in much the same way as the oxalic acid in Stahl's experiments.

These observations may usefully be applied to the chromatography of fatty acids in S-tanks. S-tanks<sup>6</sup> have several advantages over normal tanks; but when they are used for chromatographing fatty acids in solvent systems containing a little acetic acid, they have the disadvantage that the fatty acids often move as an irregular spot immediately ahead of a sharp secondary solvent front, some distance below the true solvent front. This secondary front arises from the frontal analysis or demixing of the solvent mixture; the effect is particularly pronounced in S-tanks, in which absorption of solvent vapour by the dry part of the layer is normally at a minimum<sup>7</sup>.

To overcome this problem we have found one of two alternatives necessary. Either the plate may be exposed, just before development, to acetic acid vapour for up to one minute, or about 2 per cent (based on the weight of silica gel) of oxalic acid may be incorporated into the slurry when preparing the chromatoplates. Either course ensures that free acid is dispersed over the whole adsorbent before development begins.

Of the two methods, the addition of oxalic acid is the more reliable and has given satisfactory results with oleic acid (up to at least 50  $\mu\text{g}$  per spot). The oxalic acid has not been observed to lead to isomerization of 1,3 distearin on a chromatoplate or to poor binding of adsorbent.

A suitable system for the separation of free fatty acids and glycerides is given in Table 1.

### Inhibition of Hyaluronic Acid Degradation by Dimethyl Sulphoxide

THE presence of ascorbic acid in vitreous humour<sup>1</sup> is of great importance in the process of post-mortem degradation, since hyaluronic acid, the major polysaccharide component of vitreous humour<sup>2</sup>, has been shown<sup>3</sup> to be degraded by reducing agents such as ascorbic acid and hydroquinone, in the presence of oxygen (the so-called ORD—oxidative reductive depolymerization—reaction). It is generally held that this depolymerization is brought about by free radical action, since radical scavengers such as sodium diethyldithiocarbamate have been shown<sup>4</sup> to inhibit the reaction, and in an analogous investigation of the degradation of alginate, Smidrod, Haug and Larsen<sup>5</sup> have postulated a free radical reaction with peroxide intermediates. In our examination of the preservation of human vitreous humour a major consideration has been

Table 1

the effects of external agents, such as antibiotic preservatives and their ability to participate in an ORD reaction, together with methods of preventing such degradation.

Solutions (4 ml.) of umbilical potassium hyaluronate (Fluka) (0.045 per cent) in phosphate buffer (pH 7.3, 0.3 M) were mixed in U-tube viscometers at 30° C with aqueous solutions of the following antibiotics: penicillin G (5.4 mM/l.), streptomycin sulphate (5.4 mM/l.), polymyxin B sulphate (5.0 mM/l.), neomycin sulphate (5.4 mM/l.) and tetracycline hydrochloride (5.2 mM/l.). The percentage change in specific viscosity ( $\eta_{sp}$ ) of each digest after 24 h was 2.0, < 1, 4.7, 3.9 and 65.5, respectively. The degradation by tetracycline followed an initial period of about 3 h, during which no degradation was observed. The change in  $\eta_{sp}$  of a control solution of hyaluronate mixed with de-ionized water (2 ml.) was 2.2 per cent, while another mixed with an aqueous solution (2 ml.) of vitamin K (5.4 mM/l.) showed less than 1 per cent decrease.

The considerable decrease in  $\eta_{sp}$  of the hyaluronate solution when mixed with tetracycline suggested that an ORD reaction was taking place. Attempts to show free radical inhibition in this reaction, by addition of sodium diethyldithiocarbamate, failed due to precipitation, caused by interaction between the antibiotic and the inhibitor.

However, we have found that this and other ORD type degradations of hyaluronic acid can be inhibited by dimethyl sulphoxide (DMSO). The latter was added in different proportions (0.005 ml.-0.1 ml.) to standard hyaluronate solutions (4 ml.) as used here. Solutions (2 ml.) of ascorbic acid (0.56 mM/l.), hydroquinone (0.55 mM/l.) and tetracycline (5.21 mM/l.) were then added severally to the separate digests and the changes in  $\eta_{sp}$  determined over 24 h.

In each case the degradative action of the additives was decreased by increasing concentrations of DMSO (Table 1), demonstrating that DMSO is a useful inhibitor of the ORD reaction. The finding\* that DMSO is an anti-inflammatory adjunct and a bacteriostatic agent may depend in part on the ability of DMSO to inhibit free radical biological reactions. It is of interest to note that in recent investigations connected with the storage of cornea<sup>7</sup>, DMSO has been found to be an extremely effective preservative.

## BIOCHEMISTRY

### Failure of Phenol to remove Residual Protein from Hyaluronic Acid

IN view of the successful removal of protein-containing material from carbohydrates<sup>1</sup> and from nucleic acids<sup>2</sup> by extraction with phenol, we have attempted by this means to remove the protein which remains associated with hyaluronic acid when the latter is prepared from ox synovial fluid by filtration<sup>3,4</sup>. Solutions were extracted at 0°-2° with phenol to give about equal volumes of the phenol and water-rich phases. Phenol was removed from the water-rich phase by extraction with diethyl ether or by dialysis.

Preliminary experiments showed that a single extraction would remove 80 per cent of the protein present in the filtrate obtained from synovial fluid (measured by extinction at 280 m $\mu$  after removing the phenol). Hyaluronic acid (measured as glucuronic acid by the method of Bitter and Muir<sup>5</sup>) was not extracted to a significant extent.

Table 1. ANALYSIS OF HYALURONIC ACID-PROTEIN COMPLEX BEFORE AND AFTER EXTRACTION SIX TIMES WITH PHENOL

Sample	Before extraction	After extraction
Dry wt. (mg/ml.)	0.69	0.42
Total N (mg/ml.)	0.047	0.025
Total N/dry wt. per cent	6.77	5.84
Protein per cent of dry weight	28	21

Accordingly, a sample of hyaluronic acid from which most of the filtrable protein had been removed was subjected to six successive extractions. The extracted solution was freed from phenol and its nitrogen content\* per dry weight was compared with that of the original material (Table 1). The protein contents were calculated on the bases of the analyses of Preston *et al.*<sup>4</sup>. (N content of protein 15.5 per cent; of hyaluronic acid 3.34 per cent.) It is seen that phenol extraction reduced the protein content to, but not below, the value obtained by exhaustive filtration.

### Dehydrogenation of trans-trans Farnesol by Horse Liver Alcohol Dehydrogenase

Christophe and Popjak<sup>1</sup> have recently reported that a number of prenols<sup>2</sup> could serve as substrates for horse liver alcohol dehydrogenase (LADH) but they could not act as substrates for yeast alcohol dehydrogenase. This high degree of specificity of the prenols for LADH led the same authors to propose that the physiological role of the enzyme is connected primarily with the metabolism of intermediates of sterol biosynthesis and of similar natural products, and only fortuitously with dealing with man's social habit of consuming ethanol.

During the course of a study of the specificity of LADH towards sterols<sup>11</sup> some trans-trans farnesol was prepared and tested as a substrate. This compound was of more interest than the other prenols since it had previously been implicated as being directly involved in cholesterol biosynthesis by rat liver homogenates.

Crystalline LADH was prepared according to Dalziel<sup>1</sup> except that the pure enzyme was washed 6 times with 87 per cent saturation ammonium sulphate and finally recrystallized from 10 per cent methanol. The enzyme preparation was found to be 100 per cent pure on the basis of a specific absorbancy index at 280 m $\mu$  of 0.42 ml./mg.<sup>2</sup> and a molecular weight of 84,000 per 2 coenzyme binding sites<sup>4</sup>. The enzyme concentration was expressed as N, the normality of the co-enzyme-binding capacity per litre, and was determined spectrophotometrically by titrating LADH with NAD<sup>+</sup> in the presence of excess pyrazole<sup>5</sup>. The *trans-trans* farnesol was prepared from a sample of Mann Chemical Co. farnesol by the method of Popjak and Cornforth<sup>6</sup> using a preparative gas-liquid chromatograph. The nuclear magnetic resonance spectrum of the *trans-trans* farnesol agreed with the published spectrum of Bates and Gale<sup>7</sup>.

Fig. 1 shows the Lineweaver-Burke plot for LADH-farnesol. A  $K_m$  value of 0.382 mmoles was obtained which compares quite favourably with the value of 0.600 mmoles for ethanol at pH 9.5. The maximum velocity  $v/s$  is slightly below  $k_2$  obtained with ethanol as substrate, which at pH 9 is 4.9 sec<sup>-1</sup> according to Theorell and McKinley-McKee<sup>8</sup>. The value of  $v/s$  for farnesol is about 0.3 sec<sup>-1</sup> per binding site, which is 16 times lower than the value for ethanol. The  $K_m$  and  $v/s$  values were for the conditions specified. The farnesol was dispersed in glyco-deoxycholic acid, which is a normal liver metabolite, but since a true solution of farnesol was not obtained, its effective concentration is not known and this could cause some doubt about the accuracy of the  $K_m$  value. Until more data are available it is not possible to say if the mechanism of farnesol oxidation is the same as the Theorell-Chance<sup>9</sup> mechanism for ethanol.

This evidence indicates that farnesol might be a normal physiological substrate for LADH. It is known that the human liver can dehydrogenate a maximum of 250 g of ethanol each day<sup>10</sup>; correspondingly it may be calculated that about 15 g farnesol could be oxidized to farnesal per day. Farnesol in the liver arises as a by-product of cholesterol biosynthesis, by hydrolysis of farnesyl pyrophosphate<sup>1</sup>, but it is not known what quantities of this intermediate are diverted to this alternative pathway of metabolism. The daily production of cholesterol in the human liver is about 4 millimoles, requiring the previous conversion of 8 millimoles of farnesyl pyrophosphate into squalene. If it is assumed that one-half of the farnesyl pyrophosphate synthesized acts as sterol precursor, and the other half is metabolized via free farnesol, about 0.9 g of farnesol would be available for dehydrogenation, well within the calculated capacity of the liver. Obviously, these calculations are somewhat speculative since the horse liver enzyme may be different from the human;

nevertheless, the order of magnitude of the calculated values appears to be correct.

It will be of interest to make a detailed study of the kinetics of the LADH-farnesol system and to determine if LADH can play a regulatory part in cholesterol biosynthesis by the liver. For example, one of its normal physiological functions might be to oxidize farnesol to farnesal, but when ethanol is present, it is oxidized instead of the farnesol. Further study will be required to elucidate the significance of the LADH-farnesol system.

This work was done during my tenure of a postdoctoral Fellowship, on leave of absence from Oklahoma State University. I thank Prof. Hugo Theorell for his advice, Dr. Takashi Yonetani for help in preparing the enzyme, Mr. L. E. Goran Eriksson for his help in running the nuclear magnetic resonance spectra, and Dr. George Popjak for stimulating discussions and assistance in preparation of the text.

### Effects of Pyridoxine Deficiency on the Adaptation of Rat Liver Cystathionase to DL-Ethionine and to Thyroidectomy

The activity of liver cystathionase ('soluble' cysteine desulphydrase) of rats is adaptively increased both after thyroidectomy<sup>1</sup> and after feeding DL-ethionine<sup>2</sup>. Since pyridoxal phosphate (PLP) is the co-enzyme of cystathionase<sup>3</sup>, it was of interest to determine the effect of pyridoxine deficiency on the level of liver cystathionase. Experiments were also conducted to determine the adaptive increase of cystathionase in pyridoxine-deficient rats in response to thyroidectomy and to ethionine feeding.

All experiments were performed using male and female Wistar rats with mean body-weight of 80 g. The rats were fed for 8 days the synthetic diet B (18 per cent casein) already described<sup>4</sup>. Then they were divided among groups of, at least, 6 animals per group. The first group (male rats) and the second one (female rats) were used as controls and were killed immediately. Group 3 was submitted for 8 days to the synthetic diet containing 1.5 per cent of DL-ethionine, while group 4 was thyroidectomized and fed for 10 days the synthetic diet without addition of ethionine. Thyroidectomized animals were given 1 per cent calcium lactate to drink. The other groups were given a synthetic diet similar to diet B but lacking pyridoxine. Some animals (group 5) were maintained for 3 weeks on the deficient diet before being killed, while others were thyroidectomized 10 days after the start of administration of the deficient diet and maintained on the deficient diet for 10 days after surgery. The last group (group 7) was also fed the same diet for 10 days and they received the deficient diet containing 1.5 per cent DL-ethionine for an additional week.

The preparation of the particulate free cell sap of the liver and the determination of enzymatic formation of H<sub>2</sub>S have been described previously<sup>4,5</sup>. The level of enzymatic activity was in each case estimated with and without the addition of PLP. Protein concentrations were measured according to the method of Lowry *et al.*<sup>6</sup>. All activities are expressed as  $\mu$ moles H<sub>2</sub>S produced/g protein/h.

Fig. 1. Lineweaver-Burke plot for LADH-farnesol. The rate determination of the reduction of NAD<sup>+</sup> was carried out in glycine buffer, ionic strength 0.1, pH 9.5 at 25.5°, and was measured fluorimetrically. The LADH concentration was 0.158  $\mu$ M and the NAD<sup>+</sup> concentration was 10  $\mu$ moles in 4.0 ml. total volume. Initial velocities for a period of 90 sec were measured and expressed as moles per litre per second per binding site of LADH. Since farnesol is relatively insoluble in water, it was dispersed in a solution of glyco-deoxycholic acid, pH 9.5. Glyco-deoxycholic acid cannot serve as a substrate for LADH. The dispersion used was 10 mmoles farnesol and 8 mmoles glyco-deoxycholic acid.

Table 1. EFFECTS OF VARIOUS TREATMENTS ON THE LEVEL OF ENDOGENOUS AND PLP-STIMULATED CYSTATHIONASE IN RAT LIVER

Group	Sex	Treatments	Weight of liver (g)	Cystathionase activity		Percentage saturation apo-cystathionase	Stimulation by PLP (%)
				Endogenous	PLP* stimulated		
1	♂	Controls	6.2	163 ± 7.5	310 ± 6.5	50	90
2	♂	Controls	6.0	170 ± 13	380 ± 14.5	47	113
3	♂	Ethionine treated	3.2	856 ± 56	1106 ± 91	78	89
4	♂	Thyroidectomized	5.1	380 ± 13.5	765 ± 84	50	101
5	♂	Pyridoxine deficient	5.2	74 ± 4	230 ± 12.5	32	210
6	♂	Pyridoxine deficient, thyroidectomized	5.5	118 ± 31.5	440 ± 20	28	272
7	♂	Pyridoxine deficient, ethionine treated	3.2	797 ± 63.5	1106 ± 58.5	72	39

Each value given is a mean (± standard error) of results on six rat livers. Activities are expressed as  $\mu$ moles  $H_2S/g$  protein/h.

\* PLP—pyridoxal phosphate.

Percentage of saturation =  $\frac{\text{Endogenous activity}}{\text{PLP-stimulated activity}} \times 100$ .

Stimulation by PLP =  $\frac{\text{PLP-stimulated activity} - \text{Endogenous activity}}{\text{Endogenous activity}} \times 100$ .

The results in Table 1 show that the cystathionase in the liver decreased in pyridoxine deficiency (group 5). This suggests that either the rate of enzyme synthesis is decreased or the degradation of the apo-enzyme is increased in the deficient animals due to decreased availability of the co-enzyme. But although the percentage of saturation of the apo-enzyme in the pyridoxine deficient liver (32 per cent) was low compared to the control liver (group 1, 50 per cent), enzyme activation by PLP was higher in the former (210 per cent) than in the latter group (90 per cent). This suggests that pyridoxine deficiency did not totally suppress the synthesis of apo-cystathionase.

Thyroidectomy resulted in increased level of cystathionase (group 4), but the percentage of saturation of the apo-enzyme and its activation by PLP remained essentially the same as in normal rats. When pyridoxine deficiency was superimposed on the thyroidectomized animals (group 6), the level of the endogenous and the PLP-stimulated cystathionase decreased (380 and 765 respectively in thyroidectomy compared to the corresponding figures of 118 and 440 in thyroidectomy plus pyridoxine deficiency), although these levels were higher than those of the deficient animals without thyroidectomy (group 5). The percentage of saturation of apo-cystathionase with the co-enzyme as well as the degree of activation by PLP were similar in both the deficient and deficient thyroidectomized animals. Thus pyridoxine deficiency did not eliminate but decreased the degree of inducibility of the enzyme in response to thyroidectomy.

Comparison of the data in groups 1 and 3 of Table 1 shows that the higher level of cystathionase in the liver of ethionine-fed animals is also more highly saturated with PLP (78 per cent) and has consequent lower activability by the co-enzyme (29 per cent). Pyridoxine deficiency, superimposed on the ethionine-fed animals (group 7), did not lower the high induced level of cystathionase evoked by ethionine. It is noteworthy that the percentage of saturation of the enzyme and its activation by PLP remained comparable in both the pyridoxine-deficient and normal ethionine-treated rats. These experiments clearly show that pyridoxine deprivation is without effect on the adaptive increase of cystathionase by ethionine.

Lin *et al.*<sup>9</sup> observed that the adaptive increase of the apo-enzymes of tyrosine and tryptophan transaminase in response to hydrocortisone was not impaired in pyridoxine-deficient rats. Similarly, Davis<sup>8</sup> reported that cortisone increased the endogenous level of hepatic decarboxylating activity for tyrosine and 5-hydroxytryptophan in both normal and pyridoxine-deficient rats. The present data demonstrate that while the adaptive increase of liver cystathionase in response to thyroidectomy was somewhat reduced (but by no means eliminated) in pyridoxine deficiency, that due to ethionine administration was not impaired under such conditions. The differential effect may be attributed to separate mechanisms by which the enzyme is induced to increase in the two situations. In the case of tryptophan pyrrolase, it has been suggested<sup>10</sup> that while hormonal action altered the rate of synthesis of the

enzyme, the substrates and co-factors stabilized the existing enzyme. Similarly, it is reasonable to assume that in thyroidectomized animals, the rate of synthesis of cystathionase is increased, but the decrease in the availability of PLP in pyridoxine deficiency might increase the rate of degradation of the enzyme. The sum total is a decrease, but not an abolition, of the response to thyroidectomy—as was in fact observed in the present study. The mechanism of adaptive increase of cystathionase after ethionine feeding is not clear. The high percentage of saturation of the enzyme of the ethionine-treated rats suggests an increase in available PLP in the liver of such animals. We have also recently reported<sup>11</sup> that injections of high doses of pyridoxine increased, after some hours, the percentage of saturation of liver apo-cystathionase with the co-enzyme. But the degree of increase of cystathionase as a result of ethionine administration is not fully explained by the increase of available PLP alone, since ethionine-induced level of cystathionase far surpassed the increase in the level of the enzyme obtained in rats when injected for a week with small doses of pyridoxine<sup>6</sup>.

### Effect of Ethylenediamine Tetraacetate on the Resistance of *Pseudomonas aeruginosa* to Antibacterial Agents

*Pseudomonas aeruginosa* is a resistant pathogen which is dangerous in ophthalmology<sup>1</sup>, as a hospital cross-contaminant<sup>2</sup>, and as a plant pathogen<sup>3</sup>. We have used the spectrophotometric method of Brown and Richards<sup>4</sup> to investigate the effect of disodium ethylenediamine tetraacetate (EDTA) on the action of several antibacterial agents against cultures of *Ps. aeruginosa*, NCTC 8203, in nutrient broth. It was found that the activity of polymyxin B sulphate, benzalkonium chloride and chlorhexidine diacetate against this organism was substantially increased in the presence of EDTA. Magnesium and calcium ions were found to block this potentiating

Fig. 1. The effect of EDTA on the action of polymyxin against log phase cultures of *Ps. aeruginosa* grown in nutrient broth.  
○, (A) Control; ●, (B) polymyxin, 1 unit/ml. at 192 min; △, (C) polymyxin, 1 unit/ml. at 192 min; EDTA, 6.5 μg/ml. at 216 min; □, (D) EDTA, 6.5 μg/ml. at 216 min

action. EDTA was also found to potentiate the action of polymyxin against cells grown in undiluted serum.

Replicate cultures A, B, C, and D, in 'Oxoid' nutrient broth at 37.5°, were grown into the log phase. Polymyxin was added to B and C to give 1 unit/ml. Approximately 20 min later EDTA was added to C and D to give 6.5 μg/ml. (Fig. 1). At the time of these additions the colony counts were about  $1.2 \times 10^7$ /ml. and  $2 \times 10^7$ /ml. respectively. Preliminary experiments had shown that these concentrations individually had no measurable effect on growth rate. By this procedure, control culture A was untreated, B received polymyxin 1 unit/ml., C received polymyxin 1 unit/ml. and later also EDTA 6.5 μg/ml., and D received 6.5 μg/ml. EDTA. The use of EDTA alone in higher concentrations caused lysis.

Culture C was the only one in which an effect on the growth rate was observed (Fig. 1). This culture had received doses of both chemicals which individually (B and D) had produced no observable effect. A similar phenomenon was observed when EDTA, 6.5 μg/ml., was added to cultures containing chlorhexidine, 0.7 μg/ml., and also to those with benzalkonium, 35 μg/ml. This potentiating effect of the EDTA on the action of the chemical antibacterial agents was blocked by growing the cultures in nutrient broth with magnesium chloride 50 μg/ml. (Fig. 2). Calcium chloride 18 μg/ml. had a similar blocking effect. The spectrophotometric measurements were correlated with total (chamber) and colony counts which confirmed these phenomena.

A similar experimental procedure was used to test whether the phenomenon of potentiation occurred in serum. Six replicate, log phase cultures, E, F, G, H, I and J, were grown in Burroughs Wellcome recalcified serum No. 2 containing Ca 12.1 mg/100 ml., and Mg 2.7 mg/100 ml. (Fig. 3). Culture E was untreated; EDTA was added to F, H and J at time zero to give 1,000 μg/ml.; EDTA was added to G after 290 min to give 1,000 μg/ml. and also to H and J which then each contained 2,000 μg/ml.; polymyxin was added to I and J after 305 min to give 100 units/ml. By this procedure, the control, E, was untreated, F received 1,000 μg/ml. EDTA at the start, G received EDTA after 290 min (1,000 μg/ml.), H received EDTA at the start (1,000 μg/ml.) and an equal dose after 290 min, I received polymyxin after 305 min (100 units/ml.) and J received 2 doses of EDTA (1,000 μg/ml.) and, later, polymyxin (100 units/ml.).

The addition of 1,000 μg/ml. EDTA at time zero (F) had no appreciable effect on growth rate compared to the control (E) (Fig. 3). A second equal dose of EDTA (H)

merely reduced the growth rate for about 20 min, after which time the rate increased to that of the control (E). The addition of 1,000 μg/ml. EDTA after 290 min (G) resulted in an effect similar to H and the culture recovered its original growth rate. The addition of polymyxin (100 units/ml.) (I) resulted in little appreciable effect for about 45 min, after which time there was significant lysis. J shows that polymyxin (100 units/ml.) added to cells in the presence of EDTA (2,000 μg/ml.) resulted in lysis so rapid that no reading was possible 15 min after the addition of polymyxin. Similar results were obtained using *Ps. aeruginosa*, NCTC 7244, and one strain of *Escherichia coli* with each of the three chemicals tested.

It is interesting to note that MacGregor and Elliker<sup>8</sup> found that the acquired resistance of trained *Ps. aeruginosa* cells to a quaternary ammonium compound could be eliminated, using EDTA. Repeake<sup>9</sup> found that EDTA enhanced the action of lysozyme against *Ps. aeruginosa*. The blocking effect of calcium and magnesium ions may be due to competition by the cations for the active sites; we have found that in the absence of sodium EDTA,

○, (A) Control; ●, (B) polymyxin, 1 unit/ml. at 203 min; △, (C) polymyxin, 1 unit/ml. at 203 min; EDTA, 6.5 μg/ml. at 227 min; □, (D) EDTA, 6.5 μg/ml. at 227 min

Fig. 3. The effect of EDTA on the action of polymyxin against log phase cultures of *Ps. aeruginosa* grown in undiluted serum.  
○, (E) Control; ●, (F) EDTA, 1,000 μg/ml. at start; □, (G) EDTA, 1,000 μg/ml. at 290 min; ■, (H) EDTA, 1,000 μg/ml. at start, plus further 1,000 μg/ml. at 290 min; △, (I) polymyxin, 100 units/ml. at 305 min; ▲, (J) EDTA, 1,000 μg/ml. at start, a further 1,000 μg/ml. after 290 min; polymyxin, 100 units/ml. at 305 min

calcium and magnesium ions antagonize the action of benzalkonium, chlorhexidine and polymyxin. On the other hand, these ions will chelate with the sodium salt of EDTA and they perhaps prevent chelation with ions in the cell membrane.

Our results suggest that the enhancement of anti-microbial activity by EDTA may be related to its chelating properties. Furthermore, we have found that whereas the sodium salt was effective, the magnesium salt had no apparent effect on the activity of the chemical agents tested nor did it have lytic activity alone. These observations are consistent with the hypothesis that EDTA exerts a lytic action and is synergistic with antibacterial agents by a mechanism involving removal of calcium or magnesium ions or both from the cell membrane. A closely analogous hypothesis has previously been suggested<sup>8</sup> to explain enhanced absorption of heparin from the gastro-intestinal tract of rats when it was given orally with an alkali salt of EDTA. The role of EDTA in reducing permeability barriers in biological systems would appear to have a wide significance.

We are indebted to the Medical Research Council for a grant in support of this work.

### Localization of Creatine Kinase in Microsomes and Mitochondria of Human Heart and Skeletal Muscle and Cerebral Cortex

WITHIN the framework of our investigations of the pathogenesis of progressive muscular dystrophy (Erb)<sup>1</sup>, we assumed as a hypothesis a genetically fixed defect in electrons and energy transport of the cell, to explain the symptoms of the disease, as known so far, such as variation of myoglobin, disorder in the ionic system, enzymes leaving the cytoplasmic and mitochondrial compartment of the muscular cell, etc.

One of the ferments, demonstrable in blood-serum during the illness, is creatine kinase (CK) (E.C.No.2.7.3.2.), the highest specific activity of which appears in diminishing order in human skeletal muscle, heart and cerebral cortex<sup>2</sup>. Since the discovery of CK by Lohmann<sup>3</sup>, Banga<sup>4</sup> and Kuby *et al.*<sup>5</sup>, so far as I know, no details about the localization of this ferment in mitochondria and microsomes of human brain and muscle have been published. This communication describes investigations on CK localization in the mitochondria and microsomes of human heart and skeletal muscle, and cerebral cortex, as well as of rat skeletal muscle.

Microsomes and mitochondria were isolated from heart and skeletal muscle according to the method described by Siekevitz<sup>6</sup>: cell nuclei and bigger tissue parts were centrifuged at 755*g* (2,500 r.p.m.) in the Servall centrifuge RO-2 (rotor SS 34) as well as the mitochondrial fraction at 33,000*g* (16,500 r.p.m.) and 1° C from the 10 per cent suspension (tissue/volume) produced according to Potter and Elvehjem<sup>7</sup> in a 0.88 M saccharose solution. The microsome fraction sedimented out of the supernatant at 105,000*g* (37,500 r.p.m.) in the Spinco L 50 (rotor 50). The last supernatant is called cytoplasmic fraction. Microsome and mitochondrial fractions were

suspended in 0.88 M saccharose solution and preserved at 0° C until further application.

A 10 per cent suspension in 0.88 M saccharose-solution ensued from the nuclear sediment by means of homogenization in the Bühler homogenizer (Bühler, Tübingen, Germany) at 1° C. The supernatant centrifuged at 33,000*g* (16,500 r.p.m.) and 1° C is regarded as the nuclear fraction.

Mitochondria and microsomes were isolated from brain according to the method described by Brody and Bain<sup>8</sup> with the following modifications. A buffer of 0.25 M saccharose, 0.01 M triethanolamine and 0.001 M EDTA, pH 7.4, was used for each operation. From human frontal cerebral cortex a 10 per cent suspension was produced according to Potter and Elvehjem<sup>7</sup>, which was centrifuged at 800*g* (2,800 r.p.m.), as previously reported. The sediment, re-suspended and centrifuged in half the original volume, produced sediment R<sub>1</sub>. Sediment R<sub>1</sub> was centrifuged from the two joined supernatants at 1,500*g* (3,500 r.p.m.) and the mitochondrial fraction from the supernatant at 12,000*g* (10,000 r.p.m.). From this supernatant the heavy microsome fraction was centrifuged at 23,500*g* (14,000 r.p.m.) and the light one in the Spinco L 50 at 105,000*g* (37,500 r.p.m.). The last supernatant is termed the cytoplasmic fraction.

Microsome fractions I and II as well as the mitochondrial fraction were suspended and preserved with 0° C. Sediment R<sub>1</sub> and R<sub>2</sub> were suspended as a 10 per cent tissue suspension in the Bühler homogenizer, as previously described, and from this the supernatant, that is to say the nuclear fraction, was centrifuged at 23,500*g* (14,000 r.p.m.).

Creatine kinase was determined in the optical test by NADH<sub>2</sub> with pyruvate kinase functioning as adjuvant enzyme and lactic dehydrogenase as indicator enzyme according to the modified technique of Tanzer and Gilvarg<sup>9</sup>. The deposit (final volume 3.5 ml.) contained 110 μmoles ATP, 4.2 μmoles ATP, 1.4 μmoles phosphoenolpyruvate, 0.56 μmoles NADH<sub>2</sub>, 1.5 mmoles glycine, 25 μmoles MgCl<sub>2</sub>, 0.1 mg pyruvate kinase and 0.1 mg lactic dehydrogenase, functioning as enzyme protein, as well as 1 ml. test volume, so diluted in glycine buffer pH 9 that it caused an extinction between 0.005 and 0.05 per min. The reaction was started with addition of creatine after a 10-min incubation at 25° C. During this it was measured once per minute with 366 mμ and 25° C in the 'Eppendorf' photometer (*d*=1 cm) against a zero standard (deposit without creatine). In this way inhibitory reactions such as NADH<sub>2</sub> oxidases and various ATPases could largely be excluded. Table 1 shows the averages of double determinations, where the enzyme activities are specified in μmoles creatine min<sup>-1</sup> g<sup>-1</sup> fresh weight, or extracted protein, determined according to the Biuret method<sup>10</sup>.

Relating the enzyme activity to two different quantities we gained two distinct results (Table 1). Values related to 1 g fresh weight are without exception lower and behave in some different way from those related to 1 g extracted protein.

Table 1. SPECIFIC ENZYME ACTIVITIES OF CREATINE KINASE IN FOUR OR FIVE CELL FRACTIONS OF HUMAN SKELETAL MUSCLE, HEART AND CEREBRAL CORTEX OR SKELETAL MUSCLE OF RAT

Organ	Cytoplasmic fraction	Mitochondrial fraction	Microsomal fraction 1	Microsomal fraction 2	Nuclear fraction	Total activity
Rat skeletal muscle	191(97) 1 060(111)	0.8(1) 60(6)		4.7(2) 351(40)		196(100) 959(100)
Human skeletal muscle	125(58) 5 847(153)	0.3(<1) 37(1)		0.3(<1) 107(3)	21(14) 3 359(87)	148(100) 3 829(100)
Human heart muscle	41(98) 2 585(322)	0.01(<1) 0.31(<1)		0.3(1) 439(66)	0.08(<1) 1(1)	43(100) 659(100)
Human cerebral cortex	19(74) 639(353)	1.3(5) 118(52)	0.3(1) 15(7)	0.3(1) 18(8)	5(19) 130(62)	23(100) 223(100)

Enzyme activities in μmoles creatine min<sup>-1</sup> g<sup>-1</sup> fresh weight (first line) and μmoles creatine min<sup>-1</sup> g<sup>-1</sup> extracted protein (second line). In parentheses, percentage of total activity.

The purity of the mitochondrial and microsomal fractions was tested by means of the purely cytoplasmic<sup>11</sup> lactic dehydrogenase, FDP aldolase and glutamate pyruvate transaminase as well as mitochondrial<sup>12</sup> L-glutamate dehydrogenase. Apart from this, the allocation system of the activities of mitochondrial and cytoplasmic<sup>11,12</sup> malate dehydrogenase, glutamate oxaloacetate transaminase and sorbit dehydrogenase was measured in each cell fraction. It was ascertained that an enzymatically pure mitochondrial or microsomal fraction had been produced<sup>13-14</sup>. In this connexion it became obvious that mitochondrial and cytoplasmic components were still to be found in the nucleus fraction of the three organs.

Jacobs, Heldt and Klingenberg<sup>15</sup> demonstrated the relatively high enzymatic activity of CK in the mitochondria of rat and pigeon skeletal muscle, heart and brain. CK activities of the rat quadriceps muscle, shown in Table 1, approximately coincide with those of Jacobs *et al.* In the mitochondria of human skeletal muscle (m. biceps brachii), however, a considerably smaller activity was measured, which might possibly have a connexion with the different mitochondrial contents of the various skeletal muscles or their contents of red and white muscle fibres<sup>16</sup>, as these two kinds of muscles have a clearly distinct metabolism<sup>17</sup>. The negligible CK activity of human heart muscle mitochondria, in contrast to those of rats and pigeons<sup>18</sup>, is surprising, and calls for further investigation.

Whereas greater specific activity (in relation to g fresh weight and g protein) was found in the microsomal fractions of human heart and skeletal muscle than in the respective mitochondrial fractions, the proportions in brain fractions were reversed. The enzyme activity of CK was higher in the mitochondrial fraction than in both microsomal fractions together; the total CK activity, however, quite predominant, was situated in the cytoplasmic fraction of the three organs (Table 1). Thus CK is a mainly cytoplasmic enzyme.

The small mitochondrial fraction of the enzyme seems to have a special correlation with enzymes of the respiratory chain and the citric acid cycle<sup>19</sup>; possibly it mediates in the exchange of phosphates, rich in energy, between intra- and extra-mitochondrial compartments<sup>18</sup>. Further investigations will show whether this constitutes a starting point for the investigation of cationic transport in the cell.

This work was supported by a grant from Messrs. C. F. Boehringer and Soehne, Mannheim, Germany, and carried out in the Biochemical Section of the Chemical Institute, Heidelberg University, and the Municipal Hospital, Ludwigshafen.

## Foetal Uptake of Radiocalcium in Tetracycline-treated Rats

In a recent communication we reported that the skeletal uptake of injected calcium-45 in young rats was not affected by dose levels of oxytetracycline appreciably exceeding those generally used in medical practice<sup>1</sup>. We have now extended this line of enquiry to a study of foetal radiocalcium uptake since others have reported that the tetracyclines can markedly interfere with the calcification of embryonic mineralised tissues in a number of animal species<sup>2,3</sup>. The details of this investigation are as follows:

Sprague-Dawley rats weighing 200-250 g were assigned on the first day of pregnancy to four groups (I-IV) and offered a diet previously described<sup>4</sup> containing, per kg, either 0.0 (I), 0.25 (II), 1.0 (III) or (IV) 2.0 g of oxytetracycline hydrochloride (Chas. Pfizer and Co., Inc., New York). All were given intragastrically 1.0 ml. of a solution containing 0.7  $\mu$ Ci of calcium-45 and 20  $\mu$ g of calcium (as the chloride) twice daily from the first through the twentieth day of gestation. On the twenty-first day the foetuses were delivered by Caesarean section and weighed. One femur was removed from each dam and extracted in alcohol (4 h) and in ether (8 h). These femurs and three individual foetuses from each litter were incinerated overnight at 550° C and the ash of each was dissolved in hydrochloric acid and analysed for radiocalcium<sup>5</sup>.

Food consumption and body-weight gain for the 21-day period were, respectively (mean, g,  $\pm$  S.E.): I, 249  $\pm$  16.6 and 56.7  $\pm$  13.8 (3 rats); II, 242.0  $\pm$  6.4 and 62.4  $\pm$  9.7 (5 rats); III, 255.0  $\pm$  10.2 and 73.8  $\pm$  7.3 (4 rats); IV, 247.0  $\pm$  11.5 and 65.4  $\pm$  7.7 (5 rats). None of these values differs significantly ( $P > 0.05$ ) from each other. The number of foetuses in the litters of each group were: I, 9.0  $\pm$  1.4; II, 10.4  $\pm$  0.2; III, 11.0  $\pm$  0.7; and IV, 9.0  $\pm$  0.8. Again there were no significant differences between groups nor was there with regard to the mean weight (g) of these foetuses: I, 5.3  $\pm$  0.2; II, 5.0  $\pm$  0.2; III, 4.9  $\pm$  0.3; and IV, 5.1  $\pm$  0.2. All were viable at delivery and without external developmental anomalies.

Maternal and foetal radiocalcium uptake increased with the tetracycline content of the diet (Table 1). The linear regression coefficient in each case was significantly different ( $P < 0.05$ ) from zero, indicating a positive dose-response relationship.

Table 1. EFFECT OF OXYTETRACYCLINE ON THE MATERNAL AND FOETAL UPTAKE OF RADIOCALCIUM IN RATS\*

Group	Oxytetracycline in diet (g/kg)	No. of litters	Calcium-45 (% dose/mg ash $\times 10^{-5}$ )	<sup>45</sup> Ca foetus/ <sup>45</sup> Ca femur
I	0.0	3	1.197 $\pm$ 0.066	0.593 $\pm$ 0.017
II	0.25	5	1.905 $\pm$ 0.120	0.903 $\pm$ 0.063
III	1.0	4	1.400 $\pm$ 0.066	0.832 $\pm$ 0.019
IV	2.0	5	1.453 $\pm$ 0.048	0.876 $\pm$ 0.038

\* All values expressed as mean  $\pm$  S.E.

† Based on three individual foetuses from each litter.

There is no reason to believe from our previous study<sup>1</sup> that oxytetracycline affects the skeletal fixation of circulating radiocalcium. It follows, then, that the calcium-45 content of the maternal femurs provides a measure of the gastrointestinal absorption of this isotope. On this basis it can be concluded that the antibiotic not only did not interfere with calcium absorption under these experimental conditions, but also slightly enhanced it. Further, the lack of any significant differences in the ratios of foetal-to-maternal radiocalcium (Table 1) permits the conclusion that the placental transfer of calcium was not selectively altered by tetracycline administration.

With regard to the effect of this antibiotic on calcium retention, it is of interest that penicillin has been reported to increase the index of calcium absorption in chicks<sup>6</sup>. It is also noteworthy that the tetracyclines can have a salutary effect on experimentally induced rickets in rats<sup>11,12</sup>. On the other hand, the finding that the incorporation of chlortetracycline into diets adequate in all known dietary

essentials except calcium caused no increase in body calcium retention by growing rats suggests an equivocal role for this group of antibiotics in calcium absorption.

It has been reported that tetracycline can inhibit the developing skeletal anlage of the echinoderm embryo<sup>6</sup> and in the chick embryo can interfere with growth and produce malformed bones deficient in mineral content<sup>7</sup>. Additionally, skeletal deformities have been noted in mice following administration of oxytetracycline from the fifth to the twentieth day of gestation<sup>8</sup>. Marked retardation in foetal weight has also been observed in rats following intramuscular injection of 40 mg tetracycline per kg per day from the tenth to the fifteenth day of gestation<sup>9</sup>.

In the present work up to 100 mg of oxytetracycline per kg per day (Group IV) during essentially the full course of gestation had no effect on foetal weight. This is approximately twice the recommended maximum dose for man. Further, since the percentage of ash based on net weight was the same ( $P > 0.05$ ) for all groups, it follows that tetracycline did not affect the ash content of the foetuses (these ash percentages were: I,  $1.53 \pm 0.024$ ; II,  $1.50 \pm 0.038$ ; III,  $1.55 \pm 0.029$ ; IV,  $1.54 \pm 0.035$ ).

We conclude that the oral administration of oxytetracycline to rats within the therapeutic dose range used in man does not inhibit the maternal absorption of calcium-45 or the uptake of this radioisotope by the foetus.

### Mitotic Activity in the Skin of Mice Deficient in Essential Fatty Acids

THE most striking difference between the skin of essential fatty acids deficient mice and that of normal mice is the number of layers of cells in the epidermis; the epidermis of essential fatty acids deficient mice is nearly three times thicker than normal<sup>1</sup>. A similar difference has been found in the skin of rats kept on a fat-free diet<sup>2</sup>. The greater thickness of the epidermis under these dietary conditions could conceivably have resulted from either: (a) a decrease in the rate of epidermal keratinization and cell sloughing; (b) an increase in the rate of cellular proliferation; or (c) a combination of these. The accumulation of abnormally large amounts of lipid in the cells of the distal epidermal layers of essential fatty acids deficient mice<sup>3</sup> suggested that these cells may, indeed, keratinize and slough at a slower rate than normal. The mitotic indices of the epidermis of normal and essential fatty acids deficient mice are compared in the present communication in an effort to deal with the second and third of the possible explanations for epidermal thickening.

BUB mice were kept on a fat-free diet for 10–12 weeks. The diet consisted of Fenton's casein No. 4, 5 g; salt mix No. 2, 4 g; vitamin-free test casein, 15 g; dextrose, 72 g; non-nutritive fibre, 4 g. Control mice were kept on

Purina lab. chow. A male and a female essential fatty acids deficient mouse and a control female mouse were killed in the late morning and pieces of skin from different body regions were fixed in Helly's fluid. Serial sections were cut of paraffin embedded material, and stained by the Feulgen reaction.

The results for the ear epidermis are presented in Table 1. The mitotic figures in the first two cell layers of the epidermis and the number of cells in these layers around the entire circumference of the external ear were counted. Five alternating sections per animal were observed. The mitotic indices were transformed to the arcsine for statistical analysis. The mean numbers of mitotic figures per 10,000 cells for the essential fatty acids deficient male and female mice and the control female mouse were 71, 50 and 31 respectively.

Table 1. ANALYSIS OF VARIANCE		
Source of variation	d.f.	Mean square
Total	14	
Animals	2	3025*
Error	12	167

\* Probability of difference arising from purely random variation less than 1 per cent.

Tukey's *D* test<sup>4</sup>, furthermore, showed that the mitotic indices of the female essential fatty acids deficient mouse and the female control differ significantly; the male essential fatty acids deficient mouse, however, did not differ significantly from the female control, suggesting, therefore, a sex difference in the mitotic activity of these mice.

These results thus do not eliminate the second or third possible explanations, mentioned above, for the increased thickness of the epidermis of essential fatty acids deficient mice. It is now clear, however, that the solution to the problem of what cellular activities control the thickness of the epidermis must come from studying the rates of mitosis and of keratinization during the process of thickening.

We thank Dr. Elizabeth Leduc of Brown University for providing the mice.

### Syntheses of Guanidino-substituted Penicillins and Cephalosporins

THE availability of 6-aminopenicillanic acid<sup>1</sup> and 7-aminoccephalosporanic acid<sup>2</sup> has made possible the syntheses of a number of useful semi-synthetic derivatives<sup>3</sup>. We would like to report the preparation of a new class of penicillins and cephalosporins, which have in common the presence of a guanidino group. These compounds demonstrate quite remarkable *in vivo* potencies which we feel are attributable, at least in part, to low serum binding. The following examples are cited as important analogues of this series.

Phenyldiazomethane<sup>4</sup> reacted with 6-aminopenicillanic acid to yield benzyl 6-aminopenicillanate (I), m.p. 82°–83° (found: C, 59.11; H, 5.95). Prolonged reaction using an excess of phenyldiazomethane gave a dibenzyl derivative which since it could be hydrogenated to I was presumed to be benzyl 6-benzylaminopenicillanate, m.p. 65°–67°, m.p. of hydrochloride 145° (found: C, 60.80; H, 6.48; N, 6.52; S, 7.2; Cl, 8.38). D(–)- $\alpha$ -Aminophenylacetic acid slowly reacted with either *O*-methyl pseudourea hydrochloride or *S*-methyl thiopseudourea sulphate to give

D(-)- $\alpha$ -guanidinophenylacetic acid (II), m.p. 225° (re-solidifies and decomposes at 280°) (found: C, 55.36; H, 6.07). The hydrochloride of II, m.p. 157°–159° (found: Cl, 15.5), reacted with I in the presence of dicyclohexylcarbodiimide, followed by hydrogenolysis of the protective benzyl group gave 6-[D(-)- $\alpha$ -guanidinophenylacetamido]-penicillanic acid (III), m.p. 215° dec. (found: C, 50.71; H, 5.26; N, 17.77). In mice, III is orally as active as oxacillin<sup>8</sup> against several resistant staphylococcal infections, but in addition it is highly effective against penicillin sensitive Gram-positive infections and is also high stable to acid.

*p*-Aminophenylacetic acid was treated with benzoyl cyanamide<sup>6</sup> to give *p*-N<sup>3</sup>-benzoylguanidinophenylacetic acid, m.p. 220° dec. (found: C, 64.45; H, 4.98; N, 14.14), which was hydrolysed with sodium hydroxide to give *p*-guanidinophenylacetic acid, m.p. 320° (found: C, 56.11; H, 5.50; N, 21.65). This acid could also be prepared by reaction with *S*-methyl nitrothiophenol and hydrogenation. Reaction with thionyl chloride afforded the crystalline acid chloride hydrochloride IV which was not further characterized but reacted directly with 6-amino-penicillanic acid to give 6-(*p*-guanidinophenylacetamido)-penicillanic acid (V), m.p. 195°–200° dec. (found: C, 51.96; H, 5.80). The penicillin (V) was more than ten times more effective than benzylpenicillin administered parenterally in mice against a variety of Gram-positive infections, making it the most potent penicillin that we have ever tested. It is nearly as active as ampicillin against an experimental *Salmonella* infection.

Methyl 3-bromo-2,6-dimethoxybenzoate<sup>7</sup> was treated with sodamide in liquid ammonia to give methyl 4-amino-2,6-dimethoxybenzoate, m.p. 143°–144° (found: C, 57.31; H, 6.31; N, 6.56). Reaction with benzoyl cyanamide, followed by hydrolysis, afforded 4-guanidino-2,6-dimethoxybenzoic acid hydrochloride, m.p. 218° dec. (found: C, 43.56; H, 5.04; N, 15.66). The acid chloride of this acid was condensed with I to give, after hydrogenolysis, 6-(4-guanidino-2,6-dimethoxybenzamido)-penicillanic acid (VI) (found: C, 46.96; H, 5.60; N, 14.7). This compound was also as potent as methicillin parenterally in mice against resistant staphylococcal infections.

The acid chloride (IV) also reacted with 7-aminocephalosporanic acid<sup>8</sup> to give 7-(*p*-guanidinophenylacetamido)-cephalosporanic acid (VII), gradually decomposes above 200° (found: C, 50.78; H, 4.6). It is more active than methicillin against a resistant staphylococcal infection in mice and is also more active than benzylpenicillin parenterally against penicillin sensitive infections.

## PHYSIOLOGY

### Haemoglobin Type and Reproductive Performance in Australian Merino Sheep

Two haemoglobin types can readily be distinguished in sheep and have been shown to be simply inherited<sup>1</sup>.

The reproductive performance of sheep with these haemoglobin types was investigated in a flock of Scottish Blackface ewes<sup>2</sup>, and although haemoglobin B is not common in this breed<sup>3</sup> there was a suggestion that ewes carrying the B haemoglobin gene produced more lambs at weaning than the other types in the flock. The difference was not, however, significant.

In Merino sheep in Australia, the average gene frequency for Hb.B is approximately 0.6<sup>4</sup>, although values between 0.3 and 0.7 have been noted. The simply inherited red blood cell potassium types<sup>1-3</sup> do not complicate the analysis in this breed, as practically all animals are 'LK' (low potassium)<sup>4</sup>, so the Merino is a particularly suitable breed for a re-examination of the possible association between the haemoglobin type of a ewe and the average number of lambs born and weaned per year. There has been an indication<sup>5</sup> that the actual level of potassium ion concentration in the red blood cells for 'LK' sheep may be associated with lamb production, but any such effect is relatively small and is not considered here.

This relationship has been investigated in four large experimental flocks of Merinos run by C.S.I.R.O., in which pedigrees and performance records are kept. One of these, at Cunnamulla in South-West Queensland, is under selection for various aspects of wool weight and quality<sup>6</sup> but not for any aspect of reproductive performance. Two others, at Deniliquin in the Riverina area (South) of New South Wales, are under selection for high and low twinning rate respectively<sup>6</sup>, while the fourth, also at Deniliquin, was based on a commercial ('Booroola') flock selected for multiple births, in which triplets and quadruplets are common.

Table 1 gives the average number of lambs born and weaned per year during the first 2 lambings by ewes of each Hb type in the four flocks. Ewes in the Cunnamulla flock were born from 1951 to 1957, and in the Deniliquin flocks from 1955 to 1960, so lambings occurred over a range of years in each case.

Ewes of Hb type A had fewer lambs born or weaned than those of the Hb type AB or B in every flock, the difference between AB and B being slight. In the Cunnamulla flock, the difference between Hb.A ewes and the other types was small for lambs born and larger for lambs weaned, whereas in the Deniliquin flocks the difference is approximately the same either for lambs born or lambs weaned. Sheep at both centres are lambed under supervision in yards, but at Cunnamulla the ewes are turned out of the yards into extensive grazing with no supervision, whereas at Deniliquin they are under more intensive husbandry and closer supervision.

The overall average numbers of lambs born or weaned per ewe mated are comparable for the Cunnamulla and the low-twinning flocks, but are considerably higher for the high-twinning flock and higher again for the Booroola flock. The difference in lambs weaned between Hb.A ewes and the remainder increases with the average number of lambs born in the flock. The main source of difference in lambs born in the various flocks lies in the proportion of multiple births, and in Table 2 the number of lambs per birth is given for ewes of each Hb type in the two high-producing flocks. It would seem that the superiority of the Hb.B ewes is associated in part with the production or survival of lambs from multiple births. These results, together with those reported previously from a totally different environment, strongly suggest that Hb.B confers an advantage in lamb production.

It also seems likely, however, that in some environments the advantage conferred by Hb.B with respect to lambing

Table 1. LAMBS BORN AND WEANED PER EWES MATED PER YEAR BY BREDS OF EACH HB TYPE IN FOUR FLOCKS (First two lambings for each ewe)

Hb type	Cunnamulla flock			Deniliquin flocks

Overall	977	0.91	0.72	135	0.83	0.75	184	1.10	0.96	26	1.67	1.45
$\frac{AB+B}{2} - A$		0.03	0.10		0.12	0.09		0.28	0.27		0.73	0.72

Standard deviations: Lambs born 0.23, lambs weaned 0.35.

Table 2. LAMBS PER BIRTH FOR EWES OF DIFFERENT HB TYPES IN HIGHEST-PRODUCING FLOCKS

Hb type	High twinning flock			Booroola flock		
	per cent of matings giving 0 lamb	1 lamb	2+ lambs	per cent of matings giving 0 lamb	1 lamb	2+ lambs
A	23	63	15	23	50	27
AB+B	16	54	30	15	40	45

is partially outweighed by advantages conferred by Hb.A perhaps at some stage after weaning, and that the gene frequency which is found in any breed in any environment represents a balance between these factors. The gene frequency for Hb.B is known to alter when a breed is taken from its native environment and established in a different environment<sup>7</sup>, suggesting that the relative advantages and disadvantages of Hb.A and Hb.B have also altered.

## Altitude and Athletic Performance

THE decision to hold the 1968 Olympic Games in Mexico City at an altitude of 7,500 ft. above sea-level has aroused interest in the effects of altitude on athletic performance. It has been known for some time that the maximum oxygen intake of acclimatized adults falls off right from sea-level upwards, reaching 50 per cent of the sea-level at 20,000 ft.<sup>1</sup> According to these results the decline in maximum oxygen intake at 7,500 ft. would be 8 per cent and the times for running distances of 1,500 m and more should be longer by approximately this amount. Over shorter distances, an increasingly large fraction of the total energy requirement is covered anaerobically and the decrement should be progressively smaller. In sprint events, factors such as the reduced density of the air at altitude might even lead to improved performance.

In order to obtain further information on the effect of altitude on athletic performance, the performance of the first three competitors in the

each event were averaged, and the differences between the altitude and the sea-level results, expressed as percentages of the sea-level value, were plotted against distance on a one-way logarithmic scale. The results reveal a linear relation between decrement in performance at altitude and log distance (Fig. 1). The increases in the times ranged from 2.62 per cent over 800 m to 14.9 per cent

Table 1. COMPARATIVE TIMES OF THE FIRST THREE COMPETITORS IN THE FINALS OF RUNNING EVENTS AT 7,500 FT. AND AT SEA-LEVEL

Event	Pan American Games Mexico 1965		Olympic Games Melbourne 1966	
	Min	Sec	Min	Sec

	Mean	33 : 08.5	Mean	28 : 50.5

in the 10,000 m event. Over 100 m and 400 m but not over 200 m the times at altitude were better than at sea-level.

By interpolation on this graph the predicted increase in time taken for a race lasting 6 min would be about 8 per cent, which agrees well with the results predicted from maximum exercise tests referred to here which were of this duration.

### Response of the Medial Rectus Muscle of the Cat to Succinylcholine

IN contrast to its relaxing action on most skeletal muscles, succinylcholine is well known to contract extra-ocular muscles<sup>1-3</sup>. While examining the effects of drugs on the extra-ocular muscles, it was observed that succinylcholine exerted two basically different effects on the extra-ocular muscles.

Cats were anaesthetized with sodium pentobarbital (36 mg/kg) given by intraperitoneal injection. The trachea, femoral artery and femoral vein were cannulated and artificial respiration started. The medial rectus muscle of the left eye was then separated from the globe and a suture placed through the tendon. Following immobilization of the animal's head in a stereotaxic apparatus, the tendon was attached to a Grass force displacement transducer. Through a parietal craniotomy, the dura mater was opened and the left cerebral hemisphere lifted gently to expose the third nerve. Electrical stimulation of the third nerve was affected by impaling the exposed nerve with a needle electrode delivering supramaximal rectangular pulses, 0.5 msec duration at a frequency of 0.3 c/s.

The intravenous injection of small doses of succinylcholine (less than 10 µg/kg) resulted in an increase in the resting tension of the medial rectus muscle associated with an increase in the twitch height. However, large doses of succinylcholine (30-150 µg/kg) produced a marked increase in resting tension as well as a severe reduction of the twitch response. This reduction in the twitch response was unrelated to the rise in resting tension. A typical example of this response to larger doses of succinylcholine is shown in Fig. 1. It can be seen that inhibition of the twitch persists at a time when the tension of the muscle is returning to normal. In a given animal, the smallest dose of succinylcholine required to depress the twitch height, with respect to the control, was approximately ten times greater than the smallest dose required to increase the resting tension of the muscle. The different pharmacological responses of the extra-ocular muscles to succinylcholine may be explained by anatomical observations of Hees<sup>4</sup> and Hees and others<sup>5</sup>. These authors reported two types of neuro-

muscular systems to be present in the extra-ocular muscles of the cat; a fast or twitch system, and a slow or tonic system. It would, therefore, seem reasonable to attribute the increased muscle tension seen after the intravenous injection of succinylcholine to stimulation of the tonic system, and depression of the twitch response to blockade of the fast neuromuscular system.

By means of the preparation described in this report, it is possible simultaneously to compare and contrast the effect of drugs *in vivo* on the two contractile systems present in the extra-ocular muscles of the cat.

### Membrane Potentials in Longitudinal Smooth Muscle Isolated from Guinea-pig Ileum

THE activity of the smooth muscle in guinea-pig ileum has been investigated many times. The tissue preparation most often used for such investigations has been the isolated ileum. In a number of cases, however, experiments have been carried out, not with the whole ileum, but with the thin outer layer of longitudinal smooth muscle that can be easily separated from the ileum<sup>1-3</sup>. This communication provides a brief description of membrane potentials which occur in this isolated muscle preparation. The work arose from an interest in correlating electrical activity with the transmembrane movements of potassium ion and the mechanical responses of the muscle that have been examined previously. It was desirable, therefore, to explore the feasibility of estimating changes in electrical activity in this preparation.

Membrane potentials were measured by means of the sucrose gap method<sup>4,5</sup>. An isotonic solution of potassium chloride flowed over an inactive portion of the muscle; and a physiological salt solution, over an active portion of the muscle. The composition of the physiological salt solution was: NaCl, 0.125 M; KCl, 0.0027 M; CaCl<sub>2</sub>, 0.0018 M; NaHCO<sub>3</sub>, 0.024 M; and glucose, 0.011 M. The solution was saturated with a gas mixture consisting of 95 per cent oxygen and 5 per cent carbon dioxide. The temperature was maintained between 35° C and 37° C.

**Potentials of unexcited muscle.** Sections of longitudinal muscle, placed in a sucrose gap apparatus through which the aforementioned solutions flowed, exhibited changes in membrane potentials that are illustrated in Fig. 1. The development of simple, spiked depolarizations which varied in amplitude and frequency were common occurrences. Moreover, each spike was usually preceded by a slower, more prolonged decrease in membrane potential. The slow depolarizations were often followed by a series of pre-potentials that, in turn, were followed by spikes. Slow depolarizations were also followed by complex spikes, which were more

line level. Occasionally, the downward phase of a spike extended below base-line to produce a hyperpolarization of the membrane. The hyperpolarized state was usually dispelled by a gradual return of the membrane potential to base-line level.

No precise statement can be made about the dimensions of the membrane potentials observed. However, a crude estimate of their magnitudes may be obtained by comparing potentials in the longitudinal muscle with the well-characterized potentials in the taenia coli of the guinea-pig<sup>1-7</sup>. In Fig. 2 representative records from a longitudinal muscle and a taenia coli preparation are presented side by side. Both records were obtained under the same experimental conditions. The amplitude of the spikes in the longitudinal muscle were quite small compared with those in the taenia coli.

It is known that records obtained by the sucrose gap method may not reflect the true sizes and configurations of potential changes. Changes would appear to be diminished if current flow from cell to cell encountered resistances that approached in magnitude the resistance of the extracellular space established by the sucrose solution. Asynchronous firing among the fibres of the muscle might also reduce recorded values of potential changes. The extent to which these factors have modified the results of this investigation cannot be assessed at present.

**Potentials in presence of acetylcholine.** The addition of  $5 \times 10^{-4}$  M acetylcholine evoked two groups of changes in membrane potential. One occurred during the increase in tension; the other, during the maintained tension of the muscle. The first series of changes shown in Fig. 3 (upper section) may be characterized as a gradual depolarization of the membrane on which were superimposed spiked discharges of variable amplitudes, fired at a high frequency. As peak-level of depolarization was approached the spiked discharges became less frequent or disappeared entirely. For a brief period the membrane potential remained relatively stable at the reduced level of polarization and then began to exhibit a second series of fluctuations which are illustrated in Fig. 3 (lower section). The outstanding characteristic of the latter series was the development of oscillations in potential which occurred concomitantly with a slow partial repolarization of the membrane. Occasionally, spiked dis-

Fig. 3. Changes in membrane potential and tension of longitudinal smooth muscle in the presence of acetylcholine. The record in the upper section was taken shortly after  $5 \times 10^{-4}$  M acetylcholine was added to the bathing medium. A short lag-period occurred before the drug came into contact with the muscle fibres. The record in the lower section, taken 5 min later, was obtained from the same muscle preparation. The tension recording in the lower section is at the same level as the highest level of tension shown in the upper section.

any point in the oscillatory cycle. When the drug was removed, muscle tension declined, the oscillations gradually disappeared, and the membrane potential returned to its original level or to a somewhat lower base-line.

Although the sucrose gap technique does not allow quantitative measurements of potential changes to be made, this work has shown: (1) that the isolated longitudinal muscle is capable of generating prepotentials and spiked depolarizations; (2) that acetylcholine can elicit two different series of changes in membrane potential, each associated with a different phase in the mechanical response of the muscle.

I thank Prof. H. J. Schatzmann and Prof. Walther Wilbrandt for their hospitality and advice.

The presence of similar resorption cavities in bones of patients suffering from von Recklinghausen's disease of bone, caused by overactivity of the parathyroid glands<sup>6</sup>, suggested the hypothesis that these glands may be overactive in severe skeletal fluorosis.

To test this hypothesis, four pairs of twin lambs have so far been used. One lamb received distilled water containing sodium fluoride 200 p.p.m., *ad lib.*, while its twin received distilled water alone. One pair of lambs was killed after a week on fluoride, the remaining three pairs after a month. The parathyroid glands were removed under 'Pentothal' anaesthesia, fixed in glutaraldehyde, post-fixed in osmium tetroxide, and then dehydrated and embedded in 'Araldite'. Sections were cut with glass knives on a Huxley microtome and examined by a Siemens Elmiskop 1 electron microscope. Samples of bone and kidney were also examined.

The ultrastructure of the normal sheep parathyroid gland is essentially similar to that of the three species, man<sup>7</sup>, macaque<sup>8</sup> and rat<sup>9</sup>, so far described in the literature. Unlike the primate parathyroid glands, however, there is only one cell type. The sheep parathyroid cells, furthermore, frequently contain large lipid bodies, only an infrequent finding in the other three species. These bodies, which are preserved by osmic fixation, are membrane-bound, measure up to  $5\mu$  in diameter and have a random distribution within the cell.

The ultrastructural criteria for assessing the activity of the parathyroids have been described in the glands of rats following nephrectomy<sup>10</sup> and in the rat gland grown in organ culture in a low calcium medium<sup>11</sup>.

The parathyroid glands of the lamb killed after a week's exposure to fluoride showed slight changes only. In the parathyroid glands from the lambs killed after a month's exposure, however, these changes had become quite marked: these glands were larger than the controls and the hypertrophy resulted from an increase in the size and number of the parenchymal cells and caused a reduction in the width of the intercellular space. The ergastoplasm was more extensive; the rough-surfaced endoplasmic reticulum was dilated and the normally flattened sacs were more rounded. The perinuclear space, which was normally narrow, was much wider in those

Fig. 2. Parathyroid gland from a sheep that received fluoride for one month. Two parenchymal cells are separated by a narrow intercellular space (is). The endoplasmic reticulum (er) is dilated, the perinuclear space is wider and the Golgi apparatus (G) more extensive. (Lead citrate  $\times 15,000$ )

more extensive, and the plasma membranes of the parenchymal cells had become extremely tortuous, increasing their interdigitations with those of neighbouring parenchymal cells, but not with those of adjacent endothelial cells. There was no significant alteration in the size and number of the lipid bodies.

All these changes have been observed in the parathyroid glands from nephrectomized rats<sup>10</sup>, and some of them in parathyroid glands grown in organ culture<sup>11</sup>. An increase in the size of the cells, ergastoplasmic profiles and Golgi complex are changes that were first demonstrated in the gonadotrophic and thyrotrophic cells of the pituitary gland after castration<sup>12</sup> and thyroidectomy<sup>13</sup> respectively, and are now well recognized as being indicative of increased activity in most cells.

The immunoassay of the amount of parathyroid

## PHARMACOLOGY

### Inhibition of Gastric Motility by a Commercial Duodenal Mucosal Extract containing Cholecystokinin and Pancreozymin

IN the course of the search for the hormone which results in inhibition of gastric secretion and motility after fat has entered the duodenum, the ability of duodenal extracts to inhibit the motility of denervated gastric pouches has become crucial. The presence of fat in the duodenum inhibits the spontaneous motility of Heidenhain pouches<sup>1</sup>, but many duodenal extracts which inhibit acid secretion will not do this. Extracts of duodenal mucosa containing secretin<sup>2</sup> and even more conclusively extracts containing cholecystokinin/pancreozymin<sup>3</sup> inhibit gastric acid secretion.

We have studied, in the conscious animal, the effect of these two extracts on the motility of Bickel (vagally and sympathetically denervated) pouches of the stomach in six dogs and on one transplanted pouch. Each pouch was filled with saline and connected to a pressure transducer by a water-tight indwelling stainless steel cannula. Resting motility was regular; on average contractions occurred 3-4 times per min and developed a pressure of 70 cm water. Infusion of secretin (cholecystokinin/pancreozymin, 'Vitrum'—Stockholm, Sweden) into a vein in doses of 1 unit/kg altered neither the frequency nor the force of contraction of the gastric pouch. Cholecystokinin/pancreozymin ('Vitrum'), in doses above 0.3 units/kg, on the other hand, invariably depressed the Bickel pouch. Higher doses (1.0 unit/kg) produced complete cessation of contraction for the duration of the infusion and for 10-15 min afterwards (Fig. 1).

Motility was recorded from the intact stomach by means of an air-filled balloon and again cholecystokinin/pancreozymin inhibited and secretin did not in the doses used in the Bickel pouch animals. Bile or pancreatic juice was introduced into the duodenum in a number of animals. Neither bile nor pancreatic juice depressed pouch motility, but olive oil always did. It is not possible yet to say whether the inhibition of motility observed by us or the inhibition of gastric secretion is a property of either cholecystokinin or pancreozymin or of some other substance present in the extract, but certainly this extract reproduces

Fig. 1. Upper tracing: spontaneous contractions in saline-filled denervated fundic pouch of stomach. At the end of the upper tracing the cholecystokinin/pancreozymin infusion was started and continued for the duration of the lower tracing. The contractions can be seen to get progressively smaller and eventually to disappear in the lower tracing. The duration of each tracing is 10 min.

on the stomach the physiological effect of fat in the duodenum.

### An Inhibitor of Oxytocin from the Urinary Bladder of the Toad, *Bufo marinus*

A PREVIOUS investigation has shown that the isolated bladder of the toad, *B. marinus*, releases an inhibitor of oxytocin into the bathing Ringer's solution<sup>1</sup>. More recently a similar inhibitor has been invoked to explain the inhibition of the effects of vasopressin and of adenosine-3', 5'-monophosphate on the toad bladder<sup>2</sup>. In the former investigation it was shown that inhibitor could be obtained by gently stirring isolated toad bladders in a modified Ringer's solution, and that the inhibitor so obtained was not readily dialysable. In the investigation reported here the previous results were confirmed; however, it was found that, following heat-treatment of the inhibitor solution, the inhibitor became dialysable. We report a modified preparation of the inhibitor based on this finding.

The assays for oxytocin and for inhibitor were as previously reported<sup>1</sup>, and were a modification of Bentley's method<sup>3</sup>. Synthetic oxytocin ('Syntocinon', Sandoz) was used in these experiments, usually at a concentration of 2 milliunits per ml. This concentration produced about 75 per cent of the maximal response.

The previous method of preparation of inhibitor was repeated. Two whole bladders were excised, briefly washed, and stirred in 100 ml. Ringer's solution for 2 h at 4° C. The resulting solution was dialysed for 24 h at 4° C against three changes of 20 vol. distilled water. The contents of the dialysis bag were assayed for inhibitor. At a final dilution corresponding to the inhibitor from 20 bladders/l., the response to oxytocin at a concentration of 2 milliunits/ml. was inhibited by approximately 50 per cent.

It was found that if the bladders were homogenized instead of being merely stirred, about twice the amount of inhibitor was obtained per bladder. In this case the bladders were washed in distilled water, minced with a pair of scissors, and homogenized for 1 min at medium speed in a 'Vir Tis' homogenizer. The homogenate was centrifuged at 30,000g for 15 min, and the supernatant was dialysed as before.

Heating the dialysed inhibitor solution obtained by either of the foregoing methods to 100° C did not cause an appreciable loss in inhibition. Moreover, it was found that following the heating of the solution at 100° C for 10 min the inhibitor would readily pass through a 'Viking' dialysis membrane. These observations led to the following

method of preparation: 12 bladders were briefly washed and then homogenized in 100 ml. distilled water. The homogenate was centrifuged as above, and the supernatant was dialysed against three changes of 20 vol. water. The contents of the dialysis bag were made up to 0.01 M acetic acid and kept at 100° C for 10 min. The solution was cooled and then centrifuged at 30,000*g* for 15 min to remove precipitated material. The supernatant was then dialysed against 5 vol. of water for 18 h at 4° C. The solution outside the dialysis bag contained roughly 80 per cent of the total inhibitor. This solution, about 500 ml., was concentrated in a flash evaporator to 25 ml. The concentrated solution was either frozen and stored, or taken to a powder by lyophilization. The yield of powder was quite small, and it was usually more convenient to keep the inhibitor in the concentrated solution. At a final dilution corresponding to the inhibitor from 5 to 10 bladders/l. the inhibition of 2 milliunits/ml. oxytocin was at least 50 per cent.

We conclude that the inhibitor is a molecule small enough to pass a 'Viaking' dialysis membrane and hence has a molecular weight of the order of 10,000 or less<sup>4</sup>. Its inability to dialyse before heating is possibly due to its binding to a larger molecule, this binding being sensitive to temperature. The two dialyses undoubtedly effected a partial purification of the inhibitor since, in the first, small molecules were removed and, in the second, large molecules were removed, while the overall recovery of inhibitor was apparently quite high. In some further experiments, the details of which will be reported later, it was found that this preparation also inhibited the response of the toad bladder to arginine vasotocin and of the rat uterus to oxytocin.

## HAEMATOLOGY

### Effect of Phytohaemagglutinin on Synthesis of 'Rapidly-labelled' Ribonucleic Acid in Human Lymphocytes

THE treatment of human peripheral blood leucocyte cultures with phytohaemagglutinin (PHA) causes a transformation of small lymphocytes to primitive blast cells after morphological and cytochemical changes<sup>1-4</sup>. The cells undergoing the transformation acquire the ability to synthesize DNA<sup>5,6</sup> and the morphological changes observed after 24-72 h of incubation are accompanied by an increase of RNA synthesis<sup>7,8</sup>.

In the present work the mechanism of transformation was examined by observing cell metabolism during the early stages of transformation, before any morphological change has occurred.

Thirty-minute, or one-, two- or four-hour cultures of normal human peripheral blood leucocytes ( $10^6 \pm 10$  per cent cells/ml. in TC 199 medium with 20 per cent of the subject's own plasma, at 37° C), control or PHA-treated

('Bacto'-phytohaemagglutinin M, Difco, batch No. 469791, 0.05 ml. standard sol./ml.), were given <sup>3</sup>H uridine (Amarsham, specific activity 2.7 c./mmole) at a final concentration of 2  $\mu$ c./ml. The incubation with <sup>3</sup>H uridine was interrupted after 20 min by label-diluting with non-radioactive uridine ('Sigma') to a concentration of 1 mmole and collecting by centrifugation (1,000 r.p.m. for 5 min). The cells were washed twice with TC 199 containing 20 per cent human AB+ serum, and after the last centrifugation were suspended in a drop of medium. The viability of lymphocytes was controlled by means of trypan blue staining.

The smears were made on gelatinized slides, air dried, fixed in ethanol:acetic acid mixture (3:1) and then treated for 5 min with 5 per cent trichloroacetic acid at 0° C. After 20 min washing in running water, the smears were coated with 'AR 10' Kodak emulsion and exposed at 4° C for 10 days. After the photographic procedure, autoradiographs were counterstained with Giemsa<sup>9</sup> and subjected to a quantitative analysis. Two thousand lymphocytes from each sample were analysed. The experiment was repeated twice. Results are presented in Table 1 and Fig. 1. During the first 4 h incubation no DNA synthesis in small lymphocytes has been demonstrated<sup>1-7</sup>, so methylated <sup>3</sup>H uridine incorporation into DNA can be excluded. The increase of labelled cells in PHA-treated cultures shows that more cells synthesize 'rapidly labelled' RNA. The rate of RNA synthesis, estimated from intensity of labelling, is the same in the control as in the PHA-treated cultures.

Under present experimental conditions, when pulse labelling with <sup>3</sup>H uridine was performed, one may assume that the label is incorporated in the prevalent amount into messenger RNA<sup>10</sup>. It should be emphasized that the observed phenomenon, that is, a start of RNA synthesis,

Table 1

	Number of silver grains above the cell	Time of incubation			
		30 min	60 min	120 min	240 min
Control	0-2	1,961	1,907	1,825	1,754
	3-5	32	80	120	170
	6-8	6	8	25	44
	9-11	1	4	12	14
	12-15		1	6	10
	16-20			7	2
	20-∞			5	6
Mean value of silver grains above labelled cells		4.82	4.62	6.26	5.84
PHA treated	0-2	1,962	1,904	1,512	1,189
	3-5	36	130	200	440
	6-8	8	30	102	200
	9-11	2	14	40	71
	12-15	2	16	23	68
	16-20		2	13	21
	20-∞		4	10	11
Mean value of silver grains above labelled cells		5.17	6.21	6.33	6.71

The table presents results of quantitative analysis of autoradiographs. 2,000 small lymphocytes of each group were analysed. 0-2 silver grains in nuclear emulsion above the cell were taken as a background, and these cells were not taken into account in calculation of the mean value of grains above labelled cells.

Fig. 1. Intensely labelled lymphocyte after pulse incubation with <sup>3</sup>H uridine and 240-min pre-incubation with phytohaemagglutinin.

Fig. 2. Increase of percentage of labeled lymphocytes in controls and under phytohemagglutinin treatment. Dashed line, control; solid line, PHA-treated.

may be related to the beginning of lymphocyte transformation. The transformatory mechanism of the PHA action on lymphocytes is obscure. From the present experiment one may consider the possibility that PHA initiates gene transcription in lymphocytes. If this agent affects cell membrane, its action may be connected with a change in membrane permeability to contain substances<sup>11</sup> and a subsequent imbalance of gene-histone complexes<sup>12</sup>. On the other hand, if PHA molecules with polyanionic groups in the mucoprotein fraction<sup>13</sup> are allowed to penetrate into the cell and reach the nuclear region<sup>14</sup>, they may directly affect the cationic groups of histones, changing the cistron activity. The increase in lymphocytes synthesizing RNA, in cultures without PHA, may express their environmental adaptation and may be preparatory to the blastogenic auto-transformation which is observed after longer periods of cultivation.

## Appearance of Rat Slow Alpha-two Globulin after Irradiation

Slow alpha-two globulin<sup>1</sup> (SA<sub>2</sub>G), although not demonstrable by the usual method in the sera of healthy, non-pregnant, adult rats, appears in rat sera under a large number of conditions involving growth, regeneration, necrosis, inflammation, infection or the administration of bacterial lipopolysaccharide<sup>2,3</sup>. Consequently, it was considered of interest to determine whether or not SA<sub>2</sub>G could be demonstrated in the sera of rats subjected to irradiation alone or to irradiation followed by the administration of bacterial lipopolysaccharides.

Sera were obtained from Sprague-Dawley rats of either sex as previously described<sup>4</sup>, and the presence or absence of SA<sub>2</sub>G was demonstrated by vertical starch-gel electrophoresis using the method of Smithies<sup>5</sup> with minor modifications<sup>6</sup>. The rats were exposed to approximately 600 r. of  $\gamma$ -radiation from a caesium-137 source (0.662 MeV) at a dose rate of approximately 10,000 r./h. Lipopolysaccharides from either *Salmonella abortus equi* or *S. typhosa* (Westphal type, Difco Laboratories, Detroit, Michigan) were administered intraperitoneally at the rate of 2.5–3.5 mg per rat in 0.25 ml. of 0.9 per cent sterile sodium chloride solution. Control animals were given 0.25 ml. of 0.9 per cent sodium chloride or left uninjected. The injections were made 3 or 6 days after irradiation.

The effectiveness of the radiation dosage may be judged by the observation that, while 47 unirradiated rats showed an average total white blood cell count of 16,250 per mm<sup>3</sup> (standard deviation 3,610), 40 animals examined 3 days after irradiation had an average count of 710 per mm<sup>3</sup> (standard deviation 314) and 38 rats examined 6 days after irradiation showed an average count of 451 white blood cells per mm<sup>3</sup> (standard deviation 402). The large standard deviations are due, at least in part, to the difficulties of securing accurate counts in these extreme cases of leucopenia.

The results obtained are shown in Table 1. One hundred and sixty-four examinations were made, within the first 15 days after irradiation, of sera from irradiated but uninjected rats. In 7 of these, or 4.3 per cent of the cases examined, SA<sub>2</sub>G was detected. This may be compared with 2 cases, or 1.4 per cent, of demonstrable SA<sub>2</sub>G in the sera of a consecutive series of 141 normal, untreated animals from our colony. The difference between these two rates of incidence is not statistically significant, and it may be concluded that irradiation at the dose-level here administered does not evoke the production of SA<sub>2</sub>G to the degree needed to permit its demonstration by vertical starch-gel electrophoresis.

Table 1. APPEARANCE OF SLOW ALPHA-TWO GLOBULIN AFTER IRRADIATION AND INJECTION OF LIPOPOLYSACCHARIDES

Days after irradiation	Irradiated only	No. of rats showing SA <sub>2</sub> G over No. of rats tested	
		Injected 3 days after irradiation	Injected 6 days after irradiation
0	0/23*	—	0/24*
1	0/15	0/25†	0/8
2	2/11	20/20	—
3	0/12	—	0/24†
4	2/19	15/15	12/13
5	1/18‡	4/9	11/11
6	0/8	8/8	—
7	0/12	0/1	4/5
8	0/2	0/1	—
9	0/1	0/2	—
10	2/12	0/1	2/3

\* Blood sample taken immediately before irradiation.

† Blood sample taken immediately before injection of lipopolysaccharide.

‡ Very weak SA<sub>2</sub>G band.

Of further interest is the question as to whether or not irradiated rats, despite their extreme leucopenia, are still capable of responding normally to the administration of lipopolysaccharide by the production of sufficient SA<sub>2</sub>G to permit its demonstration by starch-gel electrophoresis. The results are again shown in Table 1. None of the 49 irradiated rats showed SA<sub>2</sub>G after irradiation but before injection of the lipopolysaccharide. All such rats tested within 4 days after the administration of the lipopolysaccharide showed high levels of SA<sub>2</sub>G in their sera. The percentage of sera with demonstrable SA<sub>2</sub>G decreased thereafter approximately at the rate we have learned to expect from previous work<sup>3</sup>.

It may be concluded that, first, exposure of rats to 600 r. of  $\gamma$ -radiation does not lead to the production of SA<sub>2</sub>G demonstrable by vertical starch-gel electrophoresis and, secondly, that rats injected with bacterial lipopolysaccharide 3 or 6 days after such irradiation still respond with the production of demonstrable quantities of SA<sub>2</sub>G in a manner closely similar to that of unirradiated rats. Therefore, at least the major part of the white blood cell

system does not appear to be involved in the SA<sub>2</sub>G response to bacterial lipopolysaccharide.

### Plasminoplastin Generation Test of Normal, HF<sup>-</sup>, PTA<sup>-</sup>, X<sup>-</sup>, PTC<sup>-</sup> and AHF<sup>-</sup> Platelet-poor Plasmas: Evidence that only HF<sup>-</sup> Plasma has an Abnormal Fibrinolytic Activity

SINCE Hageman factor (HF) was found to participate in fibrinolytic activity<sup>1,2</sup> several investigations have been carried out to explore its role in fibrinolysis. Iatridis and Ferguson<sup>3</sup>, in a detailed analysis of this phenomenon, suggested that Hageman factor has a lysokinase activity which converts plasminogen-proplasminoplastin (pro-activator) into plasminoplastin (activator). Aznar *et al.*<sup>4</sup> investigated the fibrinolytic activity of Hageman factor by means of thrombelastography and concluded that the active form itself has a similar character to that of the plasminogen proactivator. Haanen *et al.*<sup>5</sup> showed that the fibrinolytic activity of a purified Hageman factor is only measurable in the presence of plasminogen, and therefore Hageman factor is an activator of plasminogen. But Iatridis and Ferguson<sup>3</sup> had shown that chicken plasma, which is deficient in proplasminoplastin (proactivator) and in Hageman factor, did not develop any plasminoplastin (activator) activity, despite the addition of streptokinase or kaolin-SF (surface factor or activation product). Thus, from this experiment and from others using normal or Hageman deficient plasmas, they concluded that activated Hageman factor is only efficient for the generation of endogenous plasminoplastin when its precursor (the proplasminoplastin) is available.

Recently Holemans and Roberts<sup>6</sup> showed that in normal persons, venous occlusion of the forearm results in an increase in fibrinolytic activity of the blood within the occluded segment, while three subjects with Hageman trait had less fibrinolytic activity. In addition they found normal fibrinolytic activity in a patient with antihaemophilic factor (AHF) deficiency before and after venous occlusion. Kamel *et al.*<sup>7</sup> showed that patients with haemophilia A, Christmas disease and von Willebrand's disease had normal fibrinolytic activity. Moreover, Phillips *et al.*<sup>8</sup> presented two cases of familial hypofibrinogenaemia with normal fibrinolytic activity.

In the work recorded here we present further evidence that plasma from Hageman trait cases is deficient in fibrinolysis too, whereas plasmas from XI<sup>-</sup>, X<sup>-</sup>, IX<sup>-</sup> and VIII<sup>-</sup> have normal fibrinolytic activity.

The method used during this investigation was the plasminoplastin generation test (PGT) of Iatridis and Ferguson<sup>3</sup> which may be briefly reviewed as follows. Two ml. of intact platelet-poor plasma diluted with 38 ml. of distilled water was adjusted to pH 5.3 with 1 per cent acetic acid, and incubated at 37° C. At successive time-intervals, 4-6 ml. samples were removed, centrifuged at 3,000 r.p.m. for 15 min at 4° C, the precipitate (euglobulin) dissolved in 0.23 ml. of borate buffer (pH 7.8) and tested for fibrinolytic activity by the euglobulin lysis time method<sup>9</sup>. The surface factor (SF) was prepared according to the previously described technique<sup>2</sup>. Well-studied cases of (XII<sup>-</sup>) Hageman trait (L.C.), (O.E.) and (A.M.), (VIII<sup>-</sup>) haemophilia A, (IX<sup>-</sup>) haemophilia B, and

(X<sup>-</sup>) Mr. R. Stuart respectively, provided bloods with these specific clotting factor deficiencies. (XI<sup>-</sup>) PTA deficiency was an artificial preparation according to Nossel's<sup>10</sup> method.

Fig. 1 shows that only plasmas from the three subjects with Hageman trait were deficient in the generation of plasminoplastin, while XI<sup>-</sup>, X<sup>-</sup>, IX<sup>-</sup> and VIII<sup>-</sup> deficient plasmas had normal plasminoplastin generation. These findings (VIII<sup>-</sup>, IX<sup>-</sup>) confirm the results of others<sup>3,7</sup> that haemophilia A and B had normal fibrinolytic activity. Also we found that X<sup>-</sup> and XI<sup>-</sup> deficient plasmas had normal fibrinolytic activity.

Fig. 2 shows the PGT on normal and Hageman deficient plasmas. The controls were run in silicone and in glass, while all other tests were in silicone. Active surface factor was added to both plasmas, and the results show a striking normalization of Hageman deficient plasma. When inactive SF (which was prepared from an exhausted plasma<sup>11</sup>) was added, no increase in the plasminoplastin generation was detected. (Compare the results with their

Fig. 1. PGT in glass on three Hageman deficient (curves 1, 2 and 3), normal (curve 4), PTA<sup>-</sup> (curve 5), PTC<sup>-</sup> (curve 6), AHF<sup>-</sup> (curve 7) and Stuart<sup>-</sup> (curve 8) plasmas

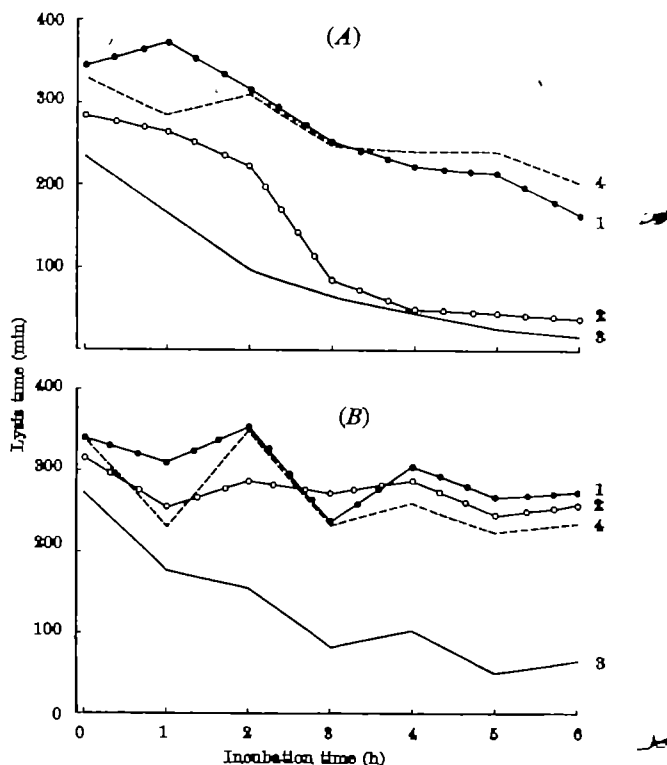

Fig. 2. PGT on (A) normal and (B) Hageman deficient plasmas. Curve 1 is a silicone control without any additive and curve 2 is a similar control in glass. The plasmas are pre-incubated, in silicone, with an active SF (curve 3) or with an inactive SF (curve 4)

respective silicone controls.) On the other hand, the control PGT performed in glass showed an increase of the plasminoplastin generation only in normal plasma, not in the Hageman deficient.

It seems, therefore, that when Hageman factor is activated, this triggers both systems: (a) the clotting mechanism; (b) the fibrinolysis. What can be demonstrated in the test-tube could very well occur *in vivo*<sup>11</sup>. Since XI, X, IX and VIII deficient plasmas, in which factor XII is normal, behave in the PGT like normal plasmas, we may conclude that factors XI, X, IX and VIII have no fibrinolytic activity and only factor XII is the link between coagulation and fibrinolysis.

## IMMUNOLOGY

### Immunological Significance of Lysosomes within Lymphocytes *In vivo*

Recent reports<sup>1,2</sup> have demonstrated the presence of lysosome-like particles in human peripheral blood lymphocytes and have shown that these increase in size and number in tissue culture following stimulation with phytohaemagglutinin. These changes appear to precede the transformation of the small lymphocytes into cells which synthesize RNA and eventually undergo mitosis. In both these reports<sup>1,2</sup> it is suggested that these lysosomes are in some way involved in the initiation of cell division.

In this work we have investigated the relative number of small lymphocytes *in vivo* which contain lysosomes, and the average number of lysosomes within lymphocytes in lymph nodes draining the site of application of a chemical sensitizing agent, at various stages during the initiation of delayed-type hypersensitivity. The development of delayed-type hypersensitivity has been shown to be associated with massive proliferation of small lymphocytes in the cortex of the draining lymph node<sup>3,4</sup>. This has been shown to occur through an intermediate large pyroninophilic cell which has many features in common with the transformed lymphocyte found following stimulation with phytohaemagglutinin *in vitro*. It was therefore essential to find out whether lymphocyte lysosomes responded *in vivo* to an immunological stimulus which would induce lymphocyte proliferation in the lymph node. An investigation was also undertaken to see whether any changes could be detected in the lysosomes within small lymphocytes in the circulation and in an inflammatory exudate in an established hyperimmune state. The system chosen was one where the animals were in an exquisitely sensitive delayed hypersensitive state to tuberculin, following the injection of dead tubercle bacilli in water-in-oil emulsion.

Guinea-pigs of the Hartley strain bred in the Institute of Dermatology were used throughout. They were exam-

ined either fresh from stock at a weight of between 400 and 500 g, or following sensitization either by one application of the chemical sensitizing agent 2-phenyl-4-ethoxymethylene-5-oxazolone (oxazolone) or by the injection of heat-killed *Mycobacterium tuberculosis* (tubercle bacilli) in water-in-oil emulsion.

Sensitization to oxazolone was with 0.2 ml. of 10 per cent oxazolone dissolved in ethanol and painted on the left ear<sup>5</sup>. Sensitization with tubercle bacilli was by injection of 1 mg of heat-killed dried bacilli (obtained from the Ministry of Agriculture Central Veterinary Laboratory, Weybridge) suspended in water-in-oil emulsion using Freund's incomplete adjuvant (Difco). Guinea-pigs were injected intramuscularly with a total of 0.8 ml. divided equally between four sites in the thighs and the nape of the neck between three and four months before the experiment. They were selected because they gave a necrotic reaction 24 h after the intradermal injection of 1.3 µg tuberculin (human PPD, obtained from the Ministry of Agriculture Central Veterinary Laboratory, Weybridge). Imprints of the left auricular lymph nodes were made from normal guinea-pigs and 2, 4 and 6 days after the application of oxazolone to the left ear.

Peritoneal exudates containing large numbers of mononuclear cells were obtained by washing out the peritoneal cavity with Hanks's balanced salt solution four days after the intraperitoneal injection of 30 ml. of sterile light liquid paraffin B.P. The cells were washed twice, diluted to a concentration of  $3 \times 10^6$  cells/ml. in 5 per cent bovine albumin (Armour, fraction V) and centrifuged lightly on to glass slides<sup>6</sup>.

Peripheral blood lymphocytes were prepared from the blood of guinea-pigs injected intravenously with 10 mg of heparin. The erythrocytes were allowed to settle following the addition of an equal volume of 5 per cent polyvinylpyrrolidone ('Polyvidone', May and Baker) in 0.15 M sodium chloride. The supernatant was first centrifuged at 150g to remove polymorphonuclear leucocytes and the residual cells in the supernatant (~90 per cent mononuclear cells) were centrifuged on to glass slides in 5 per cent bovine albumin as outlined here.

Acid phosphatase was demonstrated by the Gomori method as modified by Holt<sup>7,8</sup> using sodium-β-glycerophosphate as the substrate. The incubation medium was prepared as follows: 0.1 M sodium-β-glycerophosphate (B.D.H.), 0.003 M lead nitrate and 0.05 M acetate buffer (pH 5). The mixture was kept in the incubator at 37° C for 18 h and the precipitate was filtered. Fresh unfixed cell preparations were incubated in the substrate solution at 37° C for varying periods up to 2 h. An incubation time of 1-2 h was found to be necessary to obtain definite reactions in small lymphocytes. The slides were then immersed in a saturated solution of hydrogen sulphide prepared by bubbling hydrogen sulphide gas from a Kipp's apparatus into distilled water. They were then mounted in 8 per cent gelatine in an equal volume of glycerol and water. Control slides were incubated in the same substrate medium but containing 0.01 M sodium fluoride to inhibit the enzyme.

Lysosomes within cells of the lymphoid series were identified as granules which stained for acid phosphatase. These could be activated by pre-incubation in an acid buffer at pH 5.0 and the enzyme activity was stripped off by treating the preparation with 'Triton X 100'. Pre-treatment with distilled water increased the enzyme activity of the granules, which was also inhibited by 0.01 M sodium fluoride. The granules were therefore found to possess the property of latency of enzyme activity. By these criteria it was considered that these granules could definitely be identified with lysosomes which have been defined previously<sup>9</sup> by biochemical criteria.

An investigation was undertaken of cells in imprints of the auricular lymph nodes of normal guinea-pigs and those which had been painted with oxazolone on the left ear. Three types of cells were seen containing acid

phosphatase staining granules. One group consisted of large cells containing granules which stained after only 5-min incubation with the substrate mixture. These would appear to be cells of the macrophage series and were similar to cells in the peritoneal exudate which had ingested oil; the cytoplasm of these cells was not basophilic. A second group of large cells which had an intensely basophilic staining cytoplasm and corresponded to the large pyroninophilic cells in previous studies<sup>3,4</sup> had a much smaller number of granules which only began to stain for acid phosphatase after 20 min incubation with the substrate mixture. Finally, there were small lymphocytes which contained granules which stained optimally for acid phosphatase following 2-h incubation. As can be seen in Table 1, there was a marked increase in the proportion of small lymphocytes containing lysosomes in the lymph nodes draining an area of application of a chemical sensitizing agent. The average number of lysosomes per cell also increased, reaching a peak 4 days after sensitization, falling off on the sixth day after sensitization.

Table 1. EFFECT OF SENSITIZATION TO OXALOPHORE ON THE ACTIVITY OF LYSSOMES IN LYMPHOCTES WITHIN THE DRAINING LYMPH NODE

Auricular lymph node	Small lymphocytes Maximum per- centage of cells containing lysosomes	Mean number of lysosomes per cell	Large lymphoid cells Per cent cells containing lysosomes
Normal	10	3	19.5
2 days after sensitization	78	6.3	77
4 days after sensitization	90	9.1	93.5
6 days after sensitization	85	5.1	77.5

All figures are the mean of those found on examination of the material from six different animals. The 'large lymphoid cells' were found to have a strongly basophilic cytoplasm. Highly active macrophages which were not basophilic were not included in this series.

About 35 per cent of small lymphocytes in the peripheral blood or an oil-induced peritoneal exudate from normal guinea-pigs were found to contain lysosomes (Table 2). In guinea-pigs which had been sensitized with dead tubercle bacilli in water-in-oil emulsion 3-4 months previously, the number of small lymphocytes containing lysosomes had increased to between 80 and 90 per cent. Cells from sensitized animals contained about 10-11 lysosomes per cell as compared with 3.5-5 lysosomes per cell in normal animals. Lysosomes in small lymphocytes from sensitized animals were seen to be markedly swollen when compared with those from normal animals. Incubation of cells from peritoneal exudates with the substrate mixture for only 5 min showed that macrophages from tuberculin-sensitive animals had more active lysosomes than macrophages from normal animals.

Table 2. EFFECT OF SENSITIZATION WITH TUBERCLE BACILLI ON THE ACTIVITY OF LYSSOMES WITHIN SMALL LYMPHOCTES IN THE PERIPHERAL BLOOD AND IN A PERITONEAL EXUDATE

Source	Normal guinea-pigs		Tuberculin sensitized guinea-pigs	
	Per cent active cells	Mean No. of lysosomes per cell	Per cent active cells	Mean No. of lysosomes per cell
Peripheral blood	35 (3)	5.1	80.6 (3)	11.5
Peritoneal exudate	35.2 (5)	3.5	92.2 (5)	9.8

Figures in parentheses indicate the number of animals examined.

In an investigation of this type it is important to differentiate cells of the lymphocyte series from macrophages. Macrophages can be distinguished easily because their lysosomes appeared to have a more fragile lysosomal membrane and consequently the lysosomes stain for acid phosphatase after a shorter incubation time than cells of the lymphocyte series. Lymphocyte lysosomes would appear to be more stable than those of macrophages. Large cells of the lymphocytes series with a basophilic cytoplasm (immunoblasts) were seen in lymph nodes draining the area of application of a chemical-sensitizing agent, reaching a peak in concentration on the fourth day after sensitization. A high proportion of these cells contained lysosomes. However, these lysosomes were present in smaller numbers and were far less fragile than

those seen in macrophages. These cells would appear to be similar to those described by previous authors<sup>1,2</sup> in studies on the lysosome content of lymphoid cells in tissue cultures containing phytohaemagglutinin.

On the days immediately following the application of a chemical sensitizing agent to the skin, there was a marked increase in the number of small lymphocytes containing lysosomes in the draining lymph node. The number of active lysosomes in an active cell also increased, reaching a peak on the fourth day after sensitization. It is not known whether these cells were precursors of the immunoblasts, or were derived from them by cell division. However, they were still present in large numbers on the sixth day after sensitization, at a time when it was known that the number of immunoblasts had fallen considerably<sup>3,4</sup>. It would therefore be unlikely that these cells were about to differentiate into immunoblasts.

It may also be that small lymphocytes containing lysosomes are immunologically competent cells. It is therefore interesting that there is an increased number of small lymphocytes with lysosomes in animals injected with tubercle bacilli in water-in-oil emulsion and that these are also much larger in size and increased in number. This may also have some bearing on the increased immunological responsiveness of animals injected with Freund's adjuvant. One might also speculate on whether the small lymphocytes which contain lysosomes are the effector cells in delayed-type hypersensitivity. However, in preliminary experiments in which tuberculin has been injected intraperitoneally in a dose sufficient to cause aggregation of macrophages (10 µg PPD)\* no significant change was found in the lysosomes of either small lymphocytes or macrophages.

### Precocious Anti-diphtheria Response Induced by RNA Immuno-carrier

In previous papers an increase of the RNA content in the serum of rabbits immunized with horse serum albumin and rat or guinea-pig red blood cells was observed; the greatest increase was in the gamma-globulin fraction. The RNA extracted from immune rabbit sera (RNA Immuno-Carrier or RNA-I-C) was able to induce in normal rabbits a precocious antibody production against the same antigens used for immunizing the animals' source of the RNA<sup>1,2</sup>.

It was then found that RNA-I-C from the serum of animals immunized with heterologous RBC was able to induce rapid antibody production in normal animals of different species<sup>3</sup>. The possibility was also demonstrated of obtaining a precocious auto-haemantibody response in normal rats treated with a suitable amount of RNA-I-C from serum of rabbits immunized with rat RBC<sup>4</sup>.

The following investigations were undertaken to ascertain whether it is possible to induce a precocious antibody response in normal animals with RNA from serum of animals immunized against diphtheria toxin. Further-

more, because in preliminary experiments an attempt to obtain an effective RNA-I-C from 'stored' antitoxic horse serum was unsuccessful, we tested whether the RNA content of 'stored' immune sera was changed, and whether the capacity of inducing immunity in normal animals was modified in RNA extracted from 'stored' immune sera.

Female rabbits weighing 1.8-2.0 kg, fed on a standard diet, were immunized with 200 Lf of diphtheria toxoid ('Anadifterall' Solavo) given by four intravenous injections at four-day intervals; seven days after, a fifth injection of 50 Lf was made and, nine days afterwards, the blood of the animals was collected. One part of the serum was 'stored' at +2° C for 40 days, the remainder was used at once.

The RNA was estimated and extracted from anti-diphtheria rabbit sera 'fresh' or 'stored', according to the technique described in a previous paper<sup>3</sup>; as a control, anti-diphtheria horse serum (from Solavo, Siena, Italy) 'stored' for 40 days was used as a source of RNA.

The RNA so obtained was administered by a single intravenous injection to normal rabbits, 1.5 mg/kg body-weight; the animals were bled 48 h after the RNA injection and the sera were used in the diphtheria toxin neutralizing tests.

Four groups of male guinea-pigs weighing about 250 g (with the abdominal skin previously shaved) were used: to the first group was given subcutaneously, in a final volume of 4 ml, a mixture of various amounts of diphtheria toxin (1 ml. = 1,000 MLD; from Solavo, Siena, Italy) corresponding to 1; 2.5; 5; 7.5; 10; 15; 20 MLD, pre-incubated for 1 h at 37° C with 0.05 ml. of serum from rabbits treated with RNA-I-C from 'fresh' antitoxic serum. The second group was treated in the same way but using serum of rabbits treated with RNA-I-C from 'stored' antitoxic serum; the third and fourth groups were used as controls, using normal and hyperimmune rabbit's serum respectively.

The MRD was determined in a group of rabbits by several dilutions of toxin according to Jensen<sup>4</sup>. The MRD so determined was injected in a final volume of 0.1 ml. into the previously shaved abdominal skin of the rabbits treated 24 h before with RNA-I-C and, as a control, of hyperimmune rabbits.

Table 1. EFFECT OF 'STORAGE' ON THE RNA CONTENT OF IMMUNE SERUM

RNA mg/100 ml.	Fresh serum 9.64 ± 0.57	Stored for 40 days 5.50 ± 0.75
Per cent	100.00	58.00

Table 2. EFFECT ON GUINEA-PIGS OF VARIOUS AMOUNTS OF DIPHTHERIA TOXIN NEUTRALIZED BY VARIOUS ANTITOXIC SERA *in vitro*

Guinea-pigs treated with toxin neutralized by:	MLD of diphtheria toxin						
	1	2.5	5	7.5	10	15	20
Serum from rabbits treated with RNA-I-C from 'fresh' serum	—	—	—	—	—	—	local hyper- aemia
Serum from rabbits treated with RNA-I-C from 'stored' serum	—	—	local oedema	death	death	death	death
Normal rabbit serum	death	death	death	death	death	death	death

Table 3. *In vitro* NEUTRALIZATION OF THE DIPHTHERIA TOXIN MRD IN RABBITS BY VARIOUS ANTITOXIC SERA

	Dilutions								
	1:500	1:1,000	1:2,000	1:4,000	1:8,000	1:16,000	1:32,000	1:64,000	1:128,000
Serum of rabbits treated with RNA-I-C from 'fresh' serum	—	—	—	—	—	—	—	—	—
Serum of rabbits treated with RNA-I-C from 'stored' serum	—	—	—	—	—	—	—	+	+
Hyperimmune rabbit serum	—	—	—	—	—	—	—	+	+
Normal rabbit serum	—	—	+	+	+	+	+	+	+

Key: —, no skin reaction within 48 h; +, 8 mm erythematous halo within 48 h.

In addition, MRD neutralizing tests were made: dilutions of various antitoxic sera from 1:500 to 1:128,000 were incubated for 4 h at 37° C with the MRD of toxin and then injected, in a final volume of 0.1 ml., into the shaved abdominal skin of normal rabbits. Four groups of animals were used: to the first group was administered MRD pre-incubated with serum of rabbits treated with RNA-I-C from 'fresh' antitoxic serum, to the second the MRD pre-incubated with serum of rabbits treated with RNA-I-C from 'stored' antitoxic serum; in the third group and in the fourth the MRD pre-incubated with hyperimmune and normal rabbit serum was used.

The immune serum 'stored' for several days at +2° C undergoes a perceptible decrease of its RNA content so that, after 40 days, it is about half that of 'fresh' serum (Table 1).

RNA from 'fresh' anti-diphtheria toxin rabbit's serum, when injected into normal rabbits, elicits an antibody response which can protect guinea-pigs from the effects of the diphtheria toxin (neutralization test *in vitro*): in all the animals injected with toxin pre-incubated with serum of rabbits treated with RNA-I-C from 'fresh' antitoxic serum no paresis was found, and a hyperaemic and oedematous halo at the point of injection was observed only at the highest dose of toxin; the animals of this group were still living sixty days after treatment. Similar results were obtained in the fourth group in which antitoxic hyperimmune serum was used. All the animals of the third group, in which toxin neutralized with normal serum was used, were dead within 96 h, surviving according to the dose injected. Finally, in the guinea-pigs of the second group, in which toxin neutralized with serum of rabbits treated with RNA-I-C from 'stored' antitoxic serum was used, only those animals treated with 1, 2.5 and 5 MLD survived sixty days after treatment; the others were dead within 96 h (Table 2). Similar results were obtained using RNA-I-C from 'stored' antitoxic horse serum.

The MRD of diphtheria toxin did not induce the formation of a hyperaemic halo within 48 h in the rabbits which had received antitoxic RNA-I-C 24 h previously, or in the rabbits immunized with toxoid, used as a control. The MRD pre-incubated with normal rabbit's serum did not give a typical reaction within 48 h until serum dilutions reached 1:1,000; in the rabbits which had received the MRD neutralized with serum from animals treated with 'fresh' RNA-I-C, it was neutralized by serum diluted 1:128,000; in the rabbits treated with the MRD neutralized by serum from rabbits injected with 'stored' RNA-I-C the highest dilution able to prevent the typical hyperaemic reaction was 1:32,000 (Table 3).

As observed in our earlier work, it appears that it is possible to obtain from hyperimmune anti-diphtheria rabbit serum an RNA (RNA-I-C) that can induce a precocious anti-diphtheria response when administered by a single intravenous injection to normal rabbits. The serum of animals treated with this RNA could neutralize the diphtheria toxin *in vitro*. Storage of immune sera at +2° C affects their RNA-I-C content so that the 'stored' immune sera have a greatly decreased capacity to induce a rapid antibody response by their RNA-I-C; it is very probable that the responsibility for that is the high ribonuclease content of the serum<sup>5</sup>. Further investigations are in progress.

This investigation was supported by a grant from the National Research Council of Italy.

## PATHOLOGY

### Localization of Tumours and Drugs on the Chorio-allantoic Membrane of the Chick Embryo

BECAUSE the chick embryo is immunologically immature during the first two weeks of its development, heterologous tissues such as human and rat tumours can be grown on the highly vascular chorio-allantoic membrane (CAM) of this organism without the necessity of pre-treating it in order to suppress the immune response. Tumours grown in this way have been used to assess the effects of potential anti-tumour drugs<sup>1-4</sup>.

The technique, although seemingly very simple, is not without difficulties, and some of these are sufficiently severe to make interpretation of the results, if not impossible, certainly problematical. Two difficulties in particular have prevented the wider use of this method in testing for anti-tumour drugs: the large variation in growth rate of implanted tumour fragments, which results in uncertain control values in relatively small groups of eggs, and the sharp increase in operative mortality when successive doses of the drug under test are administered into the yolk sac or intravenously, which are the usual routes of drug administration in this system.

We sought to overcome these disadvantages by applying disks of the kind shown in Fig. 1 to the CAM and filling the six peripheral compartments with tumour cells, and the larger central well with the drug to be examined.

Fig. 1. Disk in place on the vascular CAM. The window in the shell is much enlarged in order to show the whole of the disk in position.

Our aim was twofold; first, if an approximately equal number of tumour cells were to fill the compartments of the disks, then it seemed possible that tumour nodules of approximately equal size might develop. Depression of size or weight of the nodules by a drug would then be amenable to relatively simple assessment. If, on the other hand, the tumours were found to be of different sizes, then because six tumours instead of the usual one could be grown on one CAM, statistical evaluation again of size, weight, or possibly number of 'takes' might be on somewhat firmer ground.

A second aim was to be able to give drugs in a technically simple and consistent way without at the same time applying them directly to the tumour cells, as might be done in tissue culture. It will be seen that the method we describe goes some way towards achieving these aims. (An outline of this work was given to the British Pharmacological Society, Bristol, 1964, ref. 7.)

Fertilized White Leghorn eggs were incubated at 103° F and implantation was carried out on the 8th day of incubation. The method of approaching and dropping the CAM was essentially that of Ballantyne<sup>5</sup>.

Disks were placed on to the 'dropped' CAM through the window made by removing a portion of the shell and the underlying shell membrane. They adhered closely to the CAM, the holes in the disks forming six tight outer compartments and a central well, all having the vascular CAM as their base. The disks were cut from black polythene sheet 0.0125 mm thick and each weighed 40 mg. Before use they were heat sterilized between sheets of filter paper to prevent them from curling. The disks were used once only.

In order to see how watertight the compartments were when the disks were in position on the CAM, methylene blue was dropped into them in one experiment and eosin in another. Any tendency for liquids to run together under the disks could then be followed with the naked eye when methylene blue was used, or under ultra-violet light in the case of eosin.

In the present experiments, only the Walker 256 rat carcinosarcoma in the form of a suspension of cells was used, though in another series of experiments to be reported later, other tumours were also examined.

The inoculated cells were derived from either the solid or ascitic forms of the tumour. Cells from the solid Walker tumour were packed by centrifugation and administered either in this highly concentrated form (100 per cent packed cells) or as a 10 per cent cell suspension in sterile saline. Cells from the ascitic tumour were concentrated in a similar manner; the dense upper layer of the cell pellet being withdrawn into a 0.25-ml. syringe and used directly for inoculation (100 per cent ascites cells). All suspensions were applied dropwise through a 26-gauge needle to each of the six compartments in rotation, until the total volume had been given. This varied from 0.003 to 0.03 ml. according to the cell concentration. After inoculation of the cells the eggs were sealed with 'Sellotape' and returned to the incubator.

Solutions of drugs used, in the concentration indicated in Table 1, were applied to the central well at intervals between 0 and 96 h after tumour inoculation through a small temporary slit in the 'Sellotape' seal. Drugs used were bis(2-chloroethyl) methylamine hydrochloride (mustine hydrochloride; HN2) and cyclophosphamide. They were given in a total volume of 0.05 ml. per egg. All drugs were given as a single dose except in the last experiment (see Table 1).

Eggs were inspected daily and embryos that had died before the 6th day of incubation were discarded. At that time all the embryos were killed. A segment of the CAM sufficiently large to include the disk and about 5 mm of the surrounding membrane was cut out and placed in neutral buffered formalin. The fixed membranes were then examined for the presence of tumour in the six compartments. Tumour growth in any one compartment

Table 1. EFFECT OF DRUGS ON NUMBER OF TUMOUR 'TAKES'

Tumour inoculum	Tumour (ml.)	Total dose/egg Drug	Total 'takes'	Total 'non-takes'	Variance

Total 'takes' = The sum of the number of 'takes' on each disk in the group.  
Total 'non-takes' = The sum of the number of 'non-takes' on each disk in the group.

OPA = Oxyphosphamide.

All disks had 6 inoculation sites. Evaluation was made at 8 days. Cell suspensions were made from solid Walker tumour and ascites cells were derived from the ascitic form of the tumour which included, beside tumour cells, red, white and peritoneal cells.

was rated as 1 'take' irrespective of whether one or more than one tumour nodule had developed in that compartment.

Representative samples of control and treated membranes were subjected to histological examination.

Twenty-four hours after applying the disks to the CAMs the mortality rate of the chick embryos was approximately 25 per cent of the total number of eggs operated. This rather high rate was similar to that of sham-operated eggs. Initial survival was thus not impaired by the presence of the disks on the CAMs and neither was their survival after a further 5 days incubation. Reaction of the membrane to the disks was minimal and confined to a slight thickening around the cut edges of the disks.

The number and size of blood vessels that ran across the bed of each compartment varied considerably (Fig. 1). Equally variable, taking all experiments together, appeared to be the number of tumour 'takes', but in those experiments where 100 per cent cell suspensions were used, greater uniformity of tumour development seemed to be achieved. The tumours, although derived from cell suspensions, showed a high degree of localization (Fig. 2), and while the cells might have been expected to be carried to distant sites, they grew only at or near the site of implantation. Macroscopically they did not metastasize either to other areas of the CAM or to the embryo and rarely spread beyond the outer perimeter of the disks. The experiments with methylene blue and eosin showed that a considerable degree of localization could also be obtained with solutions. When disks were properly applied, solutions were largely retained within the compartments in which they had been placed.

Fig. 2. Disk still attached to the membrane in order to show the localization of tumour nodules. Tumour derived from ascites cells

Histological examination of membranes on which disks only had been placed for six days revealed a little stromal thickening as the sole abnormality. In contrast the membranes on which nodules had developed as a result of tumour cell inoculation had numerous large nests of rapidly dividing cells of rat origin in the mesenchymal layer.

Because of the variation in numbers and size of the tumours which developed in different compartments, an analysis was made of 'takes' and 'non-takes' in the control and drug-treated eggs. The variance calculated for each of the experiments is given in Table 1. The method of comparison for all seven experiments taken together was that used by Lea<sup>8</sup> and gives a total variance of 0.1052.

The standard error is therefore  $\sqrt{0.1052} = 0.3243$ . Differences in proportion =  $2.1505 \pm 0.3243$ , that is 6.6 times the standard error, and  $P$  is less than 0.001.

Several facts emerge from these preliminary studies. First, that the CAM of the chick embryo is able to tolerate a disk of the dimensions and weight that has been applied without deleterious effects. Secondly, multiple localized foci of tumour growth can be produced by implantation of living tumour cells in the compartments of the disks, thus increasing the statistical value of each egg. Since application of drugs in the central well is also largely localized, little reaches the tumours by direct diffusion; and most of it is probably absorbed into the blood vessels or lymphatics which traverse the base of the well. Since applications are quick and technically easy, drugs can be given in equally or unequally divided doses, thereby reducing toxic effects of large single doses. This is all the more desirable since we have observed that the maximum dose tolerated by the embryo increases rapidly with increasing age, and while the maximum tolerated dose on the 1st day of the experiment may be ineffectual against the tumour, that on the 2nd day may have reached effective levels.

Thirdly, a comparison of 'takes' and 'non-takes' shows that known inhibitory substances produce a significant reduction in the number of 'takes' in the disks. This would appear to eliminate the necessity for weighing tumours from individual compartments or even the total tumour mass on each disk. It would also appear justifiable therefore to assess the potential value of a substance as an anti-tumour agent by its ability to depress the number of 'takes' in this system.

It is of course possible to vary the scheme and to test six different tumours in the peripheral compartments against one drug in the central well or indeed six different drugs against one tumour in the central well. Or one could of course use small fragments of solid tumour instead of the suspension that we have used.

Finally, six or seven different drugs may be placed into the compartments without tumour in order to assess their teratogenic effects alone or in combination.

We thank Dr. A. J. Lea for the statistical analysis of our results, E. V. Willmott and G. D. Leach for the photographs, and D. I. Duke and Ian Binks for their assistance.

## ANATOMY

## Interrelationships of the Visual Cortex and Superior Colliculus in the Cat

It is well known that in the mammal the retina is related in a well-organized manner with the lateral geniculate nucleus of the thalamus and with the visual cortex<sup>1</sup>, on one hand, and with the superior colliculus<sup>2</sup> of the midbrain, on the other. In addition, a projection from the visual and other cortical areas to the tectum has been demonstrated<sup>3</sup>. Apart from a recent investigation in the rat<sup>4</sup> there is no evidence, however, to indicate whether the projection of the cortex on the tectum is topically organized and in particular whether the parts of the cortex and tectum related to a specific part of the retina are interconnected. This problem of the interrelationships of the visual cortex and the superior colliculus has been investigated in the cat in three stages by determining, first, the detailed projection of the retina on the lateral geniculate nucleus and the superior colliculus; secondly, the organization of the projection of the lateral geniculate nucleus on the visual cortex (and thereby the representation of the retina in the cortex); and finally, the manner of termination of the cortical efferent fibres to the superior colliculus.

Following the enucleation of an eye, fragmented fibres can be traced by the method of Nauta and Gygyax<sup>5</sup> to several sites<sup>6</sup>. On the ipsilateral side, these are laminae A1, the dorsal and ventral components of the central interlaminar nucleus and the central part of the medial interlaminar nucleus of the dorsal nucleus of the lateral geniculate body, the ventral nucleus of the lateral geniculate body, the whole extent of the pretectal area (particularly the nucleus of the optic tract) and the strata opticum, griseum superficiale and griseum intermediale of the superior colliculus. On the contralateral side, terminal degeneration is found in laminae A and B, the dorsal and ventral components of the central interlaminar nucleus and the medial and lateral parts of the medial interlaminar nucleus of the dorsal lateral geniculate body, the ventral lateral geniculate nucleus, the pretectal area and nucleus of the optic tract, the same layers of the superior colliculus, and in the lateral and medial terminal nuclei of the accessory optic tract. The density of the terminal degeneration in the superior colliculus is considerably greater on the contralateral side.

The details of the representation of the retinal quadrants on the dorsal lateral geniculate nucleus<sup>7</sup> and the superior colliculus<sup>8</sup> were examined by placing small electrolytic lesions in different parts of the retina. That part of the retina lateral to the area centralis, the temporal retina, projects to the above sites on the ipsilateral side, while fibres from the retina on the nasal side of the area centralis are distributed only to the contralateral nuclei. The superior quadrants of the retina project to the anterior part of the lateral geniculate nucleus and to the posterolateral part of the superior colliculus, while the inferior quadrants project posteriorly and antero-medially respectively. In the lateral geniculate nucleus the horizontal retinal meridian is represented obliquely from posterolateral to antero-medial just behind the middle of its antero-posterior extent as viewed from the dorsal aspect, while on the colliculus this meridian is disposed obliquely from postero-medial to antero-lateral; the representations of the vertical meridian are co-extensive with the medial and anterior margins of the lateral geniculate body and superior colliculus respectively. Very small lesions in the immediate vicinity of the area centralis have shown that it projects to a little behind the middle of the medial margin of the lateral geniculate body and to the antero-lateral edge of the superior colliculus, and also that the degeneration from such lesions occupies a disproportionately large area compared with similar lesions at the periphery of the retina. There is also a well-defined

organization in the retinal projection to the interlaminar nuclei of the lateral geniculate body. In the central interlaminar nucleus the terminal degeneration found in both its dorsal and ventral components on each side always adjoins that present in the main laminae. In the medial interlaminar nucleus the upper and lower parts of the retina project respectively anteriorly and posteriorly; the central area is represented in the more dorsal parts of the nucleus, while peripheral retinal lesions cause degeneration in the ventral half. As the temporal hemiretina projects to these nuclei on the ipsilateral side, and the nasal on the contralateral, it is clear that there is an additional representation of the entire retina in each of the nuclei<sup>9</sup>.

The organization of the projection of the lateral geniculate nucleus on the cortex has been defined by correlating the site and extent of retrograde cellular changes in the thalamus following lesions of various sizes in the visual cortex as recently defined<sup>10</sup>. The nucleus projects ipsilaterally to areas 17, 18 and 19 in such a way that its anterior and posterior parts project to the corresponding portion of these areas<sup>11</sup>; in the medio-lateral dimension, however, there is a reversal in the thalamo-cortical relationship, in that medial and lateral parts of the nucleus project to the lateral and medial portions respectively of the cortex. The cellular degeneration in the central interlaminar nucleus is found to be co-extensive with that in the main laminae. Cellular degeneration is found in the medial interlaminar nucleus only when the lesion extends beyond area 17, but whether this nucleus is connected with area 18 or with area 19 or both has not been determined. The retina is therefore represented in the visual cortex with the superior quadrants anteriorly and the inferior quadrants posteriorly; the area centralis is represented near the junction of the lateral and posterolateral gyri, and the periphery of the retina along the anterior, medial and posterior borders of the visual cortex. The representation of the area centralis is relatively greater than that of the rest of the retina. The finding of a separate retinal representation in the medial interlaminar nucleus together with the differential projection of this nucleus to area 18 or area 19 (or both) may provide the anatomical basis for the additional retinal representation recently found in these areas<sup>11</sup>.

Following lesions of the visual cortex, terminal fibre degeneration is found in several subcortical nuclei<sup>12</sup>; of particular relevance are the dorsal<sup>13</sup> and ventral nuclei of the lateral geniculate body, the posterior thalamic and pulvinar complex, the pretectum and nucleus of the optic tract, and the superior colliculus. The nucleus of the optic tract receives fibres from all parts of the visual cortex, but the rest of the pretectum is found to be related only to a small inferior part of the posterolateral gyrus<sup>14</sup>. The visual cortex projects on those layers of the superior colliculus which receive retinal fibres and to the stratum zonale<sup>5</sup> in a well-organized manner, the anterior part of the cortex being related to the posterolateral half of the colliculus, and the posterior cortex to the antero-medial half. Furthermore, any part of the cortex related to a specific part of the retina sends fibres to that part of the tectum which is directly related to the same part of the retina. The degeneration in the lateral geniculate nucleus after lesions in the visual cortex is localized to those areas which project to the same parts of the cortex. Fibres are found to project to the deeper layers of the superior colliculus from other neocortical areas<sup>8</sup>.

The observations recorded here, using experimental neuroanatomical techniques, have confirmed that there is a precise representation of the retina on both the visual cortex<sup>15</sup> and the superior colliculus<sup>8</sup> in the cat and, in addition, have shown that the visual cortex projects in an equally well-organized fashion on the same layers of the tectum. Thus, every part of the retina is related to a particular part of the tectum directly, and also indirectly via the thalamus and cortex. It may be noted that,

# MISTRAL

## Refrigerator Centrifuges

In performance, compactness and appearance these three large capacity refrigerator centrifuges set new standards.

The "Mistral 6L" is the "de luxe" model and has exceptionally large capacity, incorporating such refinements as electronic speed control and preselection, stainless steel working top lid, as well as giving extremely high performance over a wide range of heads.

	"MISTRAL 6L"	"MISTRAL 4L"	"MISTRAL 2L"

Highly Successful

# ULTRA-MICROTOME

The outstanding success of this microtome for electron microscopy has resulted in rapidly-increasing sales to discriminating users, in both the New and Old Worlds, and the instrument is right at the top of its class. This is due to its unsophisticated design, simplicity and reliability in operation, plus skill and workmanship in the Cambridge tradition during manufacture.

licated design, simplicity and reliability in operation, plus skill and workmanship in the Cambridge tradition during manufacture.

**Some of the outstanding advantages:**

- Strip hinge suspension—no friction or backlash
- Mechanical specimen advance—accurate calibration of section thickness
- Fine adjustment of automatic advance—steps of  $5\text{m}\mu$  from zero to  $150\text{m}\mu$
- Full range of knife adjustments—tilt, traverse, rotation and micrometer advance
- Large specimen travel 0.1 mm by automatic advance
- Large specimen area—cuts  $3 \times 4$  mm if needed

The Cambridge Ultra-Microtome is gravity-operated, and has no motor to cause vibration.

**ULTRA-MICROTOME** (A. F. HUXLEY PATTERN)

RADIOBIOLOGY

Relation of Cell Size to the Effect of X-rays on Poliovirus Production by Monkey-kidney Cells

In several systems of animal cells in tissue culture, irradiation with either X- or gamma-rays progressively reduces the ability to produce virus (that is, the 'capacity') until it is between 1 and 10 per cent of the capacity of non-irradiated control cultures. The remaining capacity is less radiosensitive, so that a graph depicting residual capacity of the test population as a function of radiation dose tends to level off<sup>1-3</sup>.

Such a dose-response curve could indicate that the cells in the test population were of two types, with differing radiosensitivity. It was suggested that those cells the capacity of which was less radiosensitive might be larger than the other cells. Since virus production per cell increases with the size of the cell, the larger cells would synthesize more virus and might therefore require more irradiation to stop their virus synthesis<sup>4</sup>.

The evidence presented here supports that suggestion. X-irradiation reduced poliovirus yields from monkey-kidney cells of regular size more than it reduced the yields from giant monkey-kidney cells.

For these experiments, all test monolayers were prepared by plating suspensions of cells obtained from monolayers of primary monkey kidney, and those intended for giant-cell monolayers were then irradiated, as previously described<sup>5</sup>. Both the irradiated and the non-irradiated plates were incubated at 37° C in an atmosphere of 4 per cent CO<sub>2</sub> in air for 6 or 7 days, because previous experiments had demonstrated that by that time the average volume of the irradiated cells could be expected to be 4-6 times the average volume of the non-irradiated cells<sup>6</sup>. During the incubation period the medium was renewed every second day.

After incubation, the 2 groups of monolayers were separated into sets which were subjected to different doses of X-ray, ranging from 10,000 r. to 193,000 r. (see Table 1). The X-ray machine used for this irradiation was that used to prepare the giant cells and was operated at the same kV and amp (140 kV, 9 m.amp), but this time the beam was unfiltered. As controls, each experiment included one non-irradiated set of plates from each group of monolayers. In these experiments the X-ray dose corresponding to a 37 per cent survival point (the D<sub>0</sub>) was approximately 160 r. for cell multiplication and 120,000 r. for virus infectivity (Levine, unpublished data).

Table 1. EFFECT OF X-RAY DOSES ON POLIOVIRUS YIELDS FROM MONOLAYERS OF REGULAR AND OF GIANT MONKEY-KIDNEY CELLS

Experiment No.	Radiation dose (r.)	P.F.U. produced per cell		Percentage of yield from control monolayers	
		Regular	Giant	Regular	Giant
1	0	366	990	100	100
	10,000	187	1,000	51	113
	50,000	106	1,060	29	110
	100,000	106	1,060	29	110
2	0	200	425	100	100
	50,000	180	425	66	100
3	0	380	800	100	100
	100,000	72	480	20	60
4	0	37	160	100	100
	143,000	5	37	14	55
5	0	230	750	100	100
	193,000	50	465	19	62

After irradiation of the monolayers, the growth medium was removed and they were washed once with phosphate buffered saline<sup>7</sup>. Then test and control monolayers were infected with type 3 poliovirus (Leon strain) having a titre of 1.2 × 10<sup>6</sup> plaque forming units (P.F.U.) per ml. Each inoculum consisted of 0.5 ml. virus in 0.5 ml. of phosphate buffered saline. The infected monolayers were incubated at 37° C for 1 h to allow the virus to attach to the cells, and were then washed 3 times with phosphate-buffered saline, overlaid with Eagle's medium<sup>8</sup> enriched with 2 per cent calf-serum, and returned to the carbon-dioxide incubator until cells were destroyed, which was

Fig. 1. Schematic diagrams of the organization of the retinal projection on the lateral geniculate nucleus (and visual cortex) and the superior colliculus, and of the visual cortical projection on the superior colliculus. Anterior view of left retina; dorsal orthographic reconstruction of lateral geniculate body and superior colliculus; schematic view of dorsal and medial surfaces of visual cortex (PLG, postlateral gyrus; LG, lateral gyrus; PSG, postsupralateral gyrus; SG, supralateral gyrus).

although the fibres from the retina and the visual cortex end in essentially the same layers, fibres from other cortical areas terminate predominantly in the deeper 'efferent' layers<sup>9</sup>. The functional significance of the high degree of organization of these connexions is not clear; it seems probable that it is of importance in the known role of the superior colliculus in the control of eye movements and also in the centrifugal system of fibres to the retina<sup>10</sup>. Considering the well-defined organization of the projection of the optic tectum on the nucleus of origin of the centrifugal fibres to the retina of the pigeon<sup>11</sup>, the retino-tectal fibres in the cat may serve as the afferent limb of a reflex loop. Through the cortico-tectal fibres, there is also the possibility of a cortical influence on the retina.

usually 36–48 h after infection, when the virus was collected.

Virus yields were determined by plaque assay on monolayers of monkey-kidney cells. The number of cells per monolayer was determined for representative monolayers from each set before infection and was used to determine the average yield of virus per cell.

The effects of various doses of X-ray on poliovirus yields from monolayers of regular and of giant cells were compared (Table 1). Virus yields are expressed as the number of P.F.U. produced per cell and as the percentage of the yield from control monolayers. Although both the yield and the effect of the same radiation dose on the yield varied among the experiments, virus production by the giant-cell monolayers was always more radio-resistant than virus production by the regular-cell monolayers.

Although these results do not prove that the residual capacity of a cell population as a function of its radiation dose is related to the proportion of large cells in that population, they are compatible with such a relationship.

### Electron Spin Resonances in Formicidae

THE investigation of radiation phenomena in living systems, where the diffusion processes can occur in a 'normal manner', is, as recently pointed out by Zimmer *et al.*<sup>1</sup>, a most important task in present electron spin resonance research. With this in mind, investigations on the effects of ionizing radiation on survival and behaviour of ants were extended into the field of microwave spectroscopy.

So far the following species of ants have been examined in their electron spin resonance responses: *Lasius umbratus* (Nyl.), *Tetramorium caespitum* (L.), *Formica exsectoides* Forel, *Formica fusca* L., *Camponatus castaneus* (Latr.), and *Pogonomyrmex occidentalis* (Cress). The electron spin resonance spectra were recorded for each species with a Varian 4,500 series, 100 kc/s field modulation spectrometer, using a single cavity resonator and spin resonance glass tubings of 5 mm diameter as container for the living ants. DPPH and pitch were used in dual sample cavity recordings as reference standards for evaluation and comparison of the spectra. In one case, *Tetramorium*, a quantitative determination of the *g*-value could be made by frequency and magnetic field measurements with calibrated equipment at the National Bureau of Standards.

Each ant species was checked repeatedly for its electron spin resonance spectrum at different settings of the spectrometer, at different time periods and for different batches of ants. *Lasius umbratus* (Nyl.) was also examined for changes in the signal after exposure to cobalt-60  $\gamma$ -radiation (dose rate 1,550 r./min), and *Formica exsectoides* was analysed for effects of annealing on the spectrum. As expected for ants as living systems and as found in seeds and other biological objects<sup>2,3</sup>, ants exhibited in the normal state already typical electron spin resonance signals. On the basis of these signals the investigated ants could be divided into two groups: Group 1—species which showed a strong, relatively narrow signal in the free radical region (the quantitative determination of the *g*-value of the *Tetramorium* signal gave a value of 2.012) and a weaker signal in the *g*-value range of 3.5–4 (Fig. 1); Group 2—species which gave a strong 6-peak signal

covering a range of about 800 gauss with peak-to-peak distances of about 100 gauss, modulated by a more or less pronounced signal in the free radical region (Fig. 2).

Irradiation—studied in Group 1 ants—caused an increase in height of the signal, followed by a slow decay with time after irradiation (Fig. 3), and annealing, explored in ants of Group 2, changed the 6-peak signal dramatically. Annealing for 2 h at 104° C completely depressed the 6-peak signal and enhanced the free radical region signal (Fig. 4), while samples treated more gently in the biological range showed smaller changes in the shape of the signal, which returned to its original form after standing in air for several hours at room temperature.

Interpretation and identification of the observed electron spin resonance spectra are possible on the basis of existing data on some other biological objects, on

Fig. 1. Electron spin resonance pattern of normal ants. Group 1. Genera *Lasius*, *Tetramorium*, *Pogonomyrmex*

Fig. 2. Electron spin resonance pattern of normal ants. Group 2: Genera *Formica*, *Camponatus*

Fig. 3. Electron spin resonance pattern of  $\gamma$ -irradiated ants. Genera *Lasius*, *Tetramorium*, *Pogonomyrmex*. A, Control; B,  $\gamma$ -irradiated; a, 30 min after exposure; b, 60 min after exposure; c, 90 min after exposure; d, 120 min after exposure.

electron spin resonance studies in chemical and related systems as well as on survival studies with irradiated ants. The relatively narrow signal in the  $g = 2$  area without pronounced fine structure observed in ants of Group 1 compares favourably with the signals recorded for different kinds of seeds. In the seed experiments this signal has been interpreted as the result of the interaction of several processes occurring in dormant seeds, and a similar interpretation may be possible in the case of ants the chemical system of which is quite complex. Randolph and Haber<sup>4</sup> found in lettuce seeds a resonance with a  $g$ -value of perhaps 3.5, but emphasized its qualitative nature and did not give an explanation for it. Newer studies by Maling *et al.*<sup>5</sup> showed in nucleic acid complexes a signal with a  $g$ -value between 3.5 and 4, which could be related to iron. Cotzias<sup>6</sup> directed attention to the possible role of pigments in the genesis of the electron spin resonance spectrum.

The response of the ant signal to ionizing radiation has its counterpart in electron spin resonance examination with seeds. Here also the signal changed after irradiation. Increasing doses caused increase in height of the signal (number of magnetic centres), followed by a slow decay of the signal after end of the exposure. It would be of interest to investigate the relationship between the slow decay of the signal and the high radioresistance of ants, which in the case of *Tetramorium* was found to be in the order of 124,000 r. for  $LD(95)_{13}$ .

The 6-peak signal found in ants of Group 2 identifies itself by its length (600 gauss) and the peak-to-peak distance (100 gauss) as the manganese signal attributed to the  $Mn^{++}$ -ion<sup>7</sup>. This identification is supported by electron spin resonance investigations of living, manganese-containing biological objects and biochemical-chemical systems. Manganese-containing *Chlorella pyrenoidosa* exhibits a typical manganese signal which is dependent

on iron content and which changes reversibly under illumination<sup>8</sup>. Reversible annealing effects were observed in paramagnetic resonance spectra of heat-treated manganous preparations where the  $Mn^{++}$ -signal, weakened by the treatment, restored to its original form after standing for several hours in air at room temperature<sup>9</sup>, similar to the responses observed in the spectra of heat-treated *Formica*.

The work by Cohn and Leigh<sup>10</sup>, and by Mildran and Cohn<sup>11</sup>, using the paramagnetic properties of manganous ion for the examination of interaction mechanisms in enzyme-metal-substrate complexes, also invites speculation on the relationship

between these processes and similar responses in ants, which as living systems offer some intriguing challenges to electron spin resonance research.

## BIOLOGY

### A Direct Response of the Crab *Carcinus* to the Movement of the Sun

ALTHOUGH it is at first sight unlikely that a crab should take note of the direction of the Sun's movement directly, two lines of evidence already suggest this conclusion. Crabs follow with their eyes the movements of a striped drum which is revolved around them at speeds even lower than one revolution per day<sup>1</sup>, and several species of lower Crustacea<sup>2</sup> as well as the Pacific shore crab *Hemigrapsus*<sup>3</sup> utilize some feature of the path of the Sun as a basis for directional escape movements in relation to the local direction of the sea.

An advantage in working with the crab *Carcinus* is that it responds by eye movements to the movement of a single small light in a dark room. When the crab is firmly held by the carapace the crab's eyestalks follow both horizontal and vertical movements of the light. For movements which subtend angles of  $0.02^\circ$  to  $1.0^\circ$  at the crab's eye at a lamp velocity of  $0.01^\circ/\text{sec}$  the horizontal movement is 5–45 per cent of the light's movement in the horizontal plane. The light used (1.5 V, 45 mamp, 'Pinlight', Kay Electric Co., Fairfield, New Jersey) gives an illumination of approximately 0.0005 lux on a surface in the position of the crab's eye. Further work is being carried out to analyse the main attributes of the response to small lights, but the figures given here make it evident that the crab's visual system is quite able to respond directly to the movements of the Sun, full Moon ( $0.24$  lux) and perhaps some of the brighter stars.

Since the movement of the Sun has continuously changing horizontal and vertical components, the straightforward demonstration of the crab's response in the

Fig. 4. Electron spin resonance pattern of heat-treated ants. Genera *Formica*, *Osaponatus*. A, Normal; B, heat-treated.

horizontal plane has been restricted to the position at noon on midsummer day when the rate of change of altitude of the Sun passes through zero and the rate of change of azimuth (which is the projection to the horizontal plane) was  $25.3^\circ/\text{h}$  at St. Andrews (lat.  $56^\circ 20'$ ). Movement of the crab's eye was recorded with a light backwardly directed flag (weight 3 mg) mounted on the eye, and the flag moved over a horizontally mounted photocell (Texas, type LS.221). The crab's carapace was clamped facing due east at the inclination typical of normal posture, so that the Sun's azimuth moved from front to back across the right eye. The left eye faced a large sheet of black paper which continued right around the crab so that, apart from the support for the recording photocell at the rear end of the crab, no contrasting objects were present in the visual field except the horizontal artificial horizon so formed. This is essential for the experimental demonstration, because any contrasting object in the visual field cuts down the movement of both eyes, though the apparent velocities are greater for eyes which do not follow the moving object.

The horizontal movements of the right eye in the situation already described are shown in Fig. 1 with the movement of the Sun's azimuth drawn as a continuous line at half the vertical scale. As in the response to a striped drum, the eye movement is slower than the Sun's movement, being 10–40 per cent of it when few stationary contrasting objects are in the visual field. That the movements truly arise from the Sun was shown by reversing the apparent movement with a mirror. To do this, the Sun was shaded from the right eye by a large piece of black paper and a mirror to the north of the crab was used to deflect the Sun's rays on to the left eye. For the crab as a whole the motion is then reversed and the right eye is driven by the movement of the left eye. The response fails when the Sun is altogether shaded from the eyes for a short time, as in Fig. 1.

The latency of the response to the movement of the Sun, and therefore the minimum time taken by the animal to realize its escape direction, is near 10 sec of time, as shown by direct measurement from the records of the eye movements. This means that a movement of the Sun of 2 min of arc is necessary before a response is apparent above the noise-level, which is mainly caused by tremor of the eyestalk muscles.

The function of this response is not known. The reaction may be no more than a useful indicator that the animal can perceive the celestial movement directly. A possible relation to the ability of the crab to make towards the sea<sup>4</sup> when stranded on land is suspected but not yet proved. The horizontal movement of the eye cuts down the horizontal movement of the Sun across the eye, so that the rate of change of altitude of the Sun becomes a relatively more pronounced variable for the crab. This is for two reasons: first, because vertical eye movements take place over a limited range of about  $5^\circ$  in the crab;

Fig. 1. Horizontal movements of the right eye of a crab *Carcinus* facing east in response to the Sun's movement at noon. At A the Sun was obscured with black paper and at B was reflected from a mirror on to the left eye. Over the period C D the mirror was turned so that the crab had no direct or indirect view of the Sun. Note that the scale of the eye movements is twice that of the horizontal projection of the Sun's movement. Downward movement on the record is towards the west.

the eye then fails to make any more vertical response so that the vertical component of the Sun's speed becomes the vertical slip speed; and secondly, because the vertical component of the Sun's movement is too slow during most of the day to elicit a following movement by the eye. If efficient horizontal optomotor responses reduce or eliminate the horizontal component of the celestial movement, the change of Sun's altitude remains as the feature which stimulates the receptors in succession across the retina. Measurement of rate of change of altitude requires a reference to the vertical and for *Carcinus* regulation by the statocyst reflex in the pitching plane results in an eye movement of only about  $1^\circ$  for a  $10^\circ$  displacement of the crab's body on its transverse axis. For an animal without sense of time of day an error of  $\pm 1^\circ/\text{h}$  in estimation of the vertical velocity of the Sun in summer would result in an error of approximately  $\pm 9^\circ$  in the estimation of direction of escape relative to the Sun's azimuth at that moment. By using such a method the animal could substitute the Moon for the Sun with a further error which is at most equal to the inclination of the two orbits,  $5.18^\circ$ . Such a mechanism would also explain the orientation of the shore amphipod *Talitrus saltator* by moonlight<sup>5</sup> without reference to an intrinsic lunar rhythm. More sophisticated navigational abilities are not known in Crustacea; but it is possible that other animals which move towards home or in definite compass directions have the crab's ability to follow rather accurately the celestial movements.

### *Cercospora herpotrichoides* Fron on Gramineous Hosts in Ireland

CLIMATIC factors are known to affect greatly the prevalence of cereal eyespot caused by *Cercospora herpotrichoides*, leading to great variation in disease intensity in different seasons. The work of Sprague<sup>1</sup> shows that susceptibility of various gramineous species is a function of the environment; many grasses became infected in near optimum greenhouse conditions, whereas only a few species were found to be naturally infected during an intensive 7-year search in the north-western United States. These included *Bromus* and *Agropyron* species. *Agropyron repens*, however, was uninfected in the field though susceptible in the greenhouse. The very pronounced climatic effect on disease incidence and on the host range of the causal agent is shown by the prevalence of eyespot on spring-sown cereals in Scotland compared with the drier parts of southern England<sup>2</sup>, and on oat crops in the humid conditions prevalent in Ireland<sup>3</sup>. There are few records of the natural occurrence of *Cercospora herpotrichoides* on grasses in Europe, but in Holland the organism was isolated from *Alopecurus myosuroides*, *Poa pratensis* and *Apera spica-venti*<sup>4</sup>. Hosts found in Finland included *Festuca* and *Poa* species as well as *Alopecurus pratensis* and *Agropyron repens*<sup>5</sup>, while an isolate was obtained from *Agrostis stolonifera* at Rothamsted<sup>6</sup>.

In the Columbia Basin in the United States some of the prevailing grasses are claimed to be native hosts of this fungus<sup>1</sup>. The role of possible susceptible pasture and weed grasses in the more disease-prone areas of Europe cannot be overlooked. Such grasses could increase the inoculum level in the intensive cereal-producing districts while being the main if not the only factor responsible for survival of the fungus where cereals are grown infrequently.

During the summer and autumn of 1961, 1962 and 1964, studies were made of the incidence of eyespot infections on grasses in Ireland. Various grasses were collected in and adjacent to eyespot-infected wheat crops. Stems showing lesions were surface-sterilized and plated on potato dextrose agar. When a fungus resembling *Cercospora herpotrichoides* grew from the tissue, disks were obtained from pure culture and set to sporulate for identification.

Other than the cultivated cereals the only species found infected in 1961 and 1962 was *Agropyron repens* (couch grass). The only occurrence of the fungus on couch in 1961 was from an intensively cropped Co. Kilkenny wheat field, where one infected plant was found among 340 examined. This isolate, grey-black in colour, was darker than 12 isolates obtained from wheat, these varying from medium to very light grey. This colour difference persisted when the isolates were grown on different media and re-isolated after cross-infection on to wheat and couch in the greenhouse. In comparative studies on the isolate from *Agropyron repens* and a typical isolate from *Triticum vulgare* it was found that the latter had a somewhat greater growth rate (though not significant at the 5 per cent level), that it sporulated more rapidly on colonized oat grains, and caused earlier lesion development on wheat seedlings. There was no significant difference between spore length measurements of the 2 isolates. The isolates were compared for pathogenicity on *Agropyron repens* and *Triticum vulgare* in a replicated experiment (Table 1).

The couch isolate was significantly more pathogenic on couch at the 0.1 per cent level than was the wheat isolate, while the greater resistance of couch than wheat even to the isolate from couch was significant at the 1 per cent level.

In 1962, *Cercospora herpotrichoides* was isolated from *Agropyron repens* from wheat fields in counties Wexford, Waterford and Carlow. In all cases fewer than 5 per cent of shoots were infected, but the isolates in culture were variable in colour and indistinguishable from isolates obtained from wheat. It was not possible to undertake pathogenicity studies.

In 1964, a severe eyespot year, a high incidence of infected *Agropyron repens* was found in wheat crops examined in counties Meath, Waterford, Wexford and Carlow. The pathogen was also isolated from *Avena fatua*, *Lolium perenne*, *Phleum pratense* and *Cynosurus cristatus*.

A detailed study was made of an intensely couch-infected plot in Co. Waterford on which the fifth successive wheat crop was grown. On August 15, 6 random samples were taken using a circular hoop 18 in. in diameter. From each sample all wheat and couch stems bearing lesions were plated for subsequent identification of causal agents (Table 2).

Lesioned straws of wheat and couch not containing *Cercospora* most usually had *Rhizoctonia solani*, *Fusarium culmorum* or an unidentified Basidiomycete. The fact that the wheat straws were senescent by the time of isolation and may have been dominated by secondary organisms, whereas the couch shoots were still green, may be partly responsible for the practically equal recovery rate of *C. herpotrichoides* from couch and wheat. The result, nevertheless, illustrates the hitherto unrealized potential of a common species other than the cultivated cereals to act as host in a season favourable for infection in Ireland.

Table 1. MEAN PERCENTAGE INFECTION OF WHEAT AND COUCH STEMS BY ISOLATES OF *Cercospora herpotrichoides* FROM WHEAT AND COUCH

Source of isolate	<i>Triticum vulgare</i>	<i>Agropyron repens</i>
<i>T. vulgare</i>	96.1	20.8
<i>A. repens</i>	99.4	84.3
Control	0	0

Standard error of means = 2.1

Table 2. MEAN PERCENTAGE EYESPOT INFECTION OF 6 SAMPLES OF WHEAT AND COUCH FROM A COUCH-INFESTED WHEAT PLOT

	<i>Triticum vulgare</i>	<i>Agropyron repens</i>
Percentage infection	71.4	62.3

Standard error of means = 4.0

While strain examination of isolates collected in 1964 has not yet been made, the existence of different pathogenic types of the fungus shown in the 1961 studies cannot be ignored, more especially in view of the susceptibility of wheat. Different pathogenic forms of this organism relative to host specificity have been reported to date elsewhere<sup>4,7,8</sup>. Furthermore, the existence of a typical wheat isolate at least somewhat pathogenic on couch, depending on climatic conditions, illustrates the danger of higher levels of inoculum, resulting from narrow as well as broad host range types on grasses, within areas and during seasons conducive to disease development.

In tillage rotations and short-term leys the inoculum may be mainly in the form of colonized debris of the earlier-infected stubble crops. This is scarcely the case after the ploughing-up of a twenty-year-old pasture where the second spring-sown cereal on such ground often suffers severely and the first may have moderate infection. The possible role of the parasitic phase on Graminae in contributing to the inoculum-level requires thorough examination of the numerous unsown and wild species often found in such old pastures. The findings in the present studies are particularly relevant since eyespot lodging in cereal fields is often more pronounced within about 20 yards of the fence where there is greatest abundance of weed grasses such as couch.

## Petrichor and Plant Growth

It is commonly believed that the advent of rain in regions long subject to drought or desert conditions is followed by an abnormally rapid response in natural seed germination in the areas concerned. As such climatic conditions are universally favourable to the accumulation and liberation of petrichor<sup>1</sup> from clays and other silicate minerals, as components of soils, it seemed possible that some of the substances which accompany the argillaceous odour of petrichor might favourably influence the germination of seeds. Our experiments have shown that there is a marked effect but that it is unexpectedly characterized by a retardation rather than an acceleration of germination and early plant growth. It was observed that minute amounts of the oily extracts prepared from various mineral sources significantly delayed the germination and growth of cereals, mustard and mixed grass seeds. Further, it was found that seeds, shown on moistened kaolinized granite or other source material which had been previously exposed to the atmosphere under the warm, dry conditions necessary for the development of petrichor, took longer to germinate and had a slower growth rate than seeds sown on source material that had not been exposed or that had been steam-distilled and oven-dried before use. An exposure period of 2-3 weeks at 60°-75° F with a relative humidity of less than 70 per cent was sufficient to produce a small difference in growth rate. This inhibitory effect increased with prolonged exposure of the source material.

Teo<sup>2</sup> has shown that fatty acids will inhibit the auxiliary bud development of *Nicotiana glauca* plants and that the methyl esters of acids C<sub>8</sub>-C<sub>14</sub> were particularly effective in this capacity.

The acid fraction of petrichor-containing extracts, which has been analysed in some detail, consists of a series of normal fatty acids  $C_8$ - $C_{18}$  (ref. 3) and a number of nitrophenolic compounds. Identification of the latter has not yet been completed, but as relatively substantial amounts of the acids  $C_8$ ,  $C_9$  and  $C_{10}$  are present, the extracts were fractionated and the basic neutral and acid portions tested separately for growth-regulating properties.

The tests were made by treating a layer of cotton wool in a Petri dish 3.75 in. in diameter with a light petroleum (b.p. <40° C) solution of the fraction in question. The petrol was allowed to evaporate at room temperature, after which the cotton wool was moistened with 30 ml. water and sprinkled with seeds. The germination and growth rates of seeds on test trays were compared with those of seeds on control trays where light petroleum only had been added before watering and seeding.

When 1-2 mg of test samples were used (that is, 30-70 p.p.m. of water added) all three fractions decreased the growth rate of cress, mustard and grass seeds, but the effect was much stronger with the basic fraction and with some acid fractions.

Fig. 1 compares the effect of 2.5 mg of a crude basic fraction on cress seeds (No. 11) with an untreated tray (No. 12). In this case the cress withered and died before reaching maturity. 0.6 mg of basic fraction (20 p.p.m. of water) was sufficient to retard growth by 24 h or more, but did not otherwise alter the habit of growth. When a pasture mixture of perennial rye grass, wild white clover, ladens clover, cocksfoot, cowgrass and *Phalaris* was treated with the basic material, the foliated species—which germinate several days earlier than the grasses—were slow growing and remained stunted, but the grass after germination grew strongly.

The nitrophenolic compounds were separated from the fatty acids by esterifying the acids with a 12 per cent solution of  $BF_3$  in methanol and extracting the acidic nitrophenolic compounds from a light petroleum solution of the esters with sodium hydroxide. The nitrophenols were recovered from the acidified aqueous alkali by extraction with petrol. The shoot growth of all seeds tested was retarded strongly by 0.5 mg or more of the mixed nitrophenols, while root growth, particularly in the case of grasses, was very vigorous.

Reference samples of stearic and palmitic acid when applied in amounts of 1-2 mg did not produce any noticeable retardation, but the same quantity of octanoic, nonanoic and decanoic acid did so. The methyl esters of the combined acids and a reference sample of methyl nonanoate tended to increase growth rates. This suggests that in this instance the inhibitory effect of acids may be a function of pH.

Petrol solutions of the total petrichor extracts and neutral fractions aged on standing a few weeks and lost their potency. This could result from either oxidation or interaction of the compounds in solution, but as the isolated basic and nitrophenolic fractions did not age readily, interaction appears to be the major factor.

It can be seen that the growth-regulating properties of these extracts are not due to a single inhibitory principle or to the acids alone, but to the combined action of a

number of components in the mixture. As the composition of extracts from source materials exposed in widely separated areas has been found to be similar, it seems likely that compounds associated with the formation of petrichor will have a significant effect on seed germination and early plant growth in areas intermittently subjected to prolonged dry periods.

## MICROBIOLOGY

### Use of Streptomycin in the Separation of Nucleic Acids from Protein in a Bacterial Extract

It is well known that in bacterial extracts, in contrast to extracts from animal tissues, nucleic acids interfere markedly with the isolation and separation of proteins, for example in chromatographic separation on substituted cellulose columns. Protamine sulphate and manganese chloride<sup>1</sup> have been used to precipitate selectively nucleic acids from the protein; these methods have often proved difficult and have resulted in much loss of protein. More recently, streptomycin or dihydrostreptomycin<sup>2</sup> have been used. In order satisfactorily to separate the protein components of an extract of *Lactobacillus plantarum* (N.C.I.B. 6376) it was necessary to reduce the nucleic acid content of these extracts. The protamine sulphate method was found to be unreliable due to lack of reproducibility, even under rigidly controlled conditions. Accordingly, the streptomycin method was investigated.

The ratio of the 280 to 260 m $\mu$  absorbance gives an indication of the protein:nucleic acid ratio. In the untreated extracts from *L. plantarum* this ratio is usually 0.55 to 0.57. Substantial removal of the nucleic acids is indicated when the ratio is above 1.0. For purposes of comparison, a 280/260 m $\mu$  ratio of 0.7 is equivalent to about 0.12 mg nucleic acid/mg protein, and a ratio of 1.0 to about 0.033 mg nucleic acid/mg protein<sup>3</sup>. However, as these figures are only approximate, it is considered better to use the 280/260 m $\mu$  ratio.

The bacterial extracts were prepared in a Linnane blender<sup>4</sup>. The protein obtained by the addition of ammonium sulphate to 80 per cent saturation was dissolved in 0.1 M phosphate buffer, pH 7.0, and dialysed in a rotary dialyser against about 1,200 times the volume of 0.0016 M phosphate buffer, pH 7.0, at 5° C. This dialysis step was found to be of crucial importance and accordingly a highly efficient dialyser was constructed. With this apparatus and using 'Visking' dialysis tubing size 8/32 in., equilibrium was achieved for small ions (for example,  $PO_4^{3-}$ ,  $SO_4^{2-}$ ,  $Na^+$  etc.) in about 3 h. Thus, the buffer was changed after the first 3 h of dialysis and dialysis continued for a further 28 h.

The precipitation of nucleic acids with streptomycin depends on the salt concentration of the solution<sup>5,6</sup> and, to a first approximation, the salt concentration is inversely proportional to the specific resistance of the solution. At intervals the extract was removed from the dialyser and its specific resistance measured with a Philips conductivity meter (type GM 4249/01) and cell (PR 9510/00) at 0° C. Fractions of the extract were then diluted to 10 mg protein/ml. with dialysing buffer and streptomycin sulphate (10 per cent w/v solution, pH 7.0,

Fig. 1

Evans Medical Australia (Pty.) Ltd.) was added in the amounts indicated in Fig. 1. The extract was stirred continuously with a magnetic stirrer and kept at 0°C during the slow addition of the streptomycin. The solutions were then centrifuged and the absorbances of the supernatants at 280 and 260 mμ were measured in a Unicam 'S.P. 500' spectrophotometer.

Fig. 1 shows that the degree of selective precipitation of nucleic acids depends on the salt content of the solution. As the salt concentration is lowered, and the specific resistance rises, so the degree of selective precipitation improves. The optimal salt concentration depends on the salts present<sup>1,2</sup> and probably on the source of the extract as well.

Two additional features were noted in these experiments: (1) The precipitation is not affected over the pH range from 6.0 to 8.0. It should be noted that this is most probably due to the very low concentration of phosphate buffer used. Donovan *et al.*<sup>3</sup> found that the precipitation of DNA by streptomycin could be prevented by phosphate buffer and the concentration needed was dependent on pH. However, their concentrations of phosphate were about 10 times higher than that used here. (2) The higher the amount of streptomycin added, compared with the protein content of the extract, the smaller the loss of protein. With the specific resistance of the extract =  $26.3 \times 10^3 \Omega$ , and the ratio of mg streptomycin sulphate/mg protein = 0.5, the loss of protein was 35 per cent using the biuret method, and when this ratio was 1.0 the loss was 24 per cent. This latter figure compares favourably with the best results obtained by the older protamine sulphate precipitation method<sup>4</sup> and is more easily reproduced.

At concentrations of streptomycin sulphate greater than 3 mg/mg protein, the 280/260 mμ ratio of all extracts approaches a value of 0.9 (see Fig. 1). The reason for this may be that at these concentrations of streptomycin, relatively more protein than nucleic acids may be precipitated than at lower concentrations. This point was not checked, as the biuret estimation is unreliable in the presence of high amounts of streptomycin and the use of the absorbance at 280 and 260 mμ to estimate protein<sup>5,6</sup> is too inaccurate while this ratio is changing.

Fig. 1. Addition of 10 per cent (w/v) streptomycin sulphate, pH 7.0, to a dialysed extract from *Lactobacillus plantarum*. ○, Specific resistance (SR),  $1.12 \times 10^3 \Omega$ ; ●, SR,  $5.98 \times 10^3 \Omega$ ; △, SR,  $16.5 \times 10^3 \Omega$ ; □, SR,  $41.9 \times 10^3 \Omega$ .

Thus the use of streptomycin sulphate in the selective precipitation of nucleic acids from bacterial extracts, as outlined here, appears to have many advantages over the older methods. These include reproducibility, moderately low loss of protein, pH independence, combined with a convenient method of monitoring the crucial dialysis step.

### Culture *in vitro* of *Giardia* Trophozoites from the Rabbit and Chinchilla

*Giardia* may well rank among the earliest described intestinal protozoa. Dobell<sup>1</sup> contends that these were the organisms that Leeuwenhoek in 1681 described from his own faeces. *Giardia* may cause intestinal disease in man. The presence of large numbers of these organisms in the small intestine is often associated with a syndrome that includes diarrhoea, epigastric pain and loss of appetite. Oral administration of atabrine usually results in the prompt disappearance of the symptoms and of the organisms. *Giardia* are also thought to be a cause of enteritis in chinchillas<sup>2</sup>.

The genus *Giardia* includes a variety of binucleate flagellate protozoan parasites which inhabit the intestinal tract of mammals (including man), birds, reptiles, amphibians and fish. *Giardia* occur in trophozoite and cyst form. Each trophozoite has eight flagella and a sucking disk, with which it attaches to the epithelium of the small intestine of its host. Metamorphosis to the cyst form occurs as trophozoites are swept down the intestine. It is as cysts that these organisms are transferred from host to host. Excystation takes place after swallowed cysts reach the small intestine. In a suitable environment, trophozoites multiply repeatedly by binary fission.

Despite their ubiquity, antiquity and possible pathogenicity, no member of the genus *Giardia* had been cultured *in vitro* until quite recently. In 1960, Karapetyan<sup>3</sup> described a method with which he had cultured *Giardia* trophozoites from man for seven months. Karapetyan established his culture in a complex medium in the presence of chicken fibroblasts and *Candida guilliermondii*. Once the *Giardia* were established, they continued to multiply even though the fibroblasts died out and were not replaced; in the absence of *Candida*, however, the *Giardia* failed to survive. Later, Karapetyan<sup>4</sup> reported culturing *Giardia* trophozoites from the rabbit for five months in a complex medium to which *Saccharomyces cerevisiae* was added at the time of inoculation; fibroblasts were not used. This report concerns our experience with Karapetyan's method of culturing *Giardia* trophozoites; to our knowledge no other workers have reported any attempts to use it.

We have not been able to culture *Giardia* from the rabbit using Karapetyan's method. Repeatedly, many trophozoites persist in the culture tube for 4 to 7 days, after which time their numbers decrease; no trophozoites survive more than 11 days.

Karapetyan's method involves an initial addition of yeast to the culture, then the daily replacement of two-thirds of the culture fluid with fresh medium. Reasoning that a certain number of metabolizing yeast may be necessary for *Giardia* survival, and that Karapetyan's strain of *S. cerevisiae* may have differed from ours in multiplying more rapidly in this medium, we modified the method by daily adding viable yeast as well as culture medium. This modification proved successful; using it, we have cultured *Giardia* trophozoites from the rabbit for 18 months, and *Giardia* trophozoites from the chinchilla for 14 months. Our success suggests the possibility that these two organisms can be cultured indefinitely with this method.

*Giardia* trophozoites for inocula were obtained from animal intestine with both the methods fully described by Karapetyan<sup>4</sup>. Stock cultures were kept and examined in 16 × 125 mm Leighton type tissue culture tubes (Bellco Glass, Inc., Vineland, New Jersey) plugged with silicone rubber stoppers. Organisms to be examined with the oil immersion objective or the phase microscope were cultured in tissue culture chambers of the type developed by Rose<sup>5</sup>. The procedure for the establishment of cultures is shown in Table 1.

Day	Removed from tube	Table 1 Added to tube
0	—	2.0 ml. Karapetyan's medium No. 1 (K) 0.2 ml. yeast suspension (Y) 0.1 ml. inoculum 1.0 ml. K
2	2.0 ml. culture fluid	0.1 M NaHCO <sub>3</sub> to bring pH to 7.2-7.4 1.0 ml. K 0.2 ml. Y 0.1 M NaHCO <sub>3</sub> as above, if necessary
3	1.7 ml. culture fluid	1.5 ml. K 0.2 ml. Y 0.1 M NaHCO <sub>3</sub> as above, if necessary

The procedure used on day 3 is used on all subsequent days.

As described by Karapetyan<sup>4</sup>, medium No. 1 contains chick embryo extract, human serum, a tryptic meat digest and Hanks's solution. The yeast suspension is made by dispersing one loopful of a 48-h culture of *S. cerevisiae* from a Sabouraud dextrose agar slant in 1.0 ml. of medium No. 1. Incubation temperature is 37° C.

The trophozoites attach to, and eventually completely populate, the flat inner surface of the Leighton tube. This surface is scanned microscopically each day, and the approximate number of organisms per low-power field is noted. Tubes which contain about ten trophozoites per low-power field on the day after inoculation often have about 1,000 trophozoites per low-power field 5 to 8 days later. Culture fluid from such tubes contains many trophozoites and can be used as inoculum to make subcultures by the method described above. The formation of *Giardia* cysts has never been observed in 18 months of daily examination.

We have tried repeatedly to maintain established cultures of *Giardia* trophozoites in Karapetyan's medium without added viable yeast. Consistently, the *Giardia* in such cultures have died in 1-2 weeks. Resumption of daily additions of yeast to tubes almost devoid of trophozoites results in vigorous growth and division of the protozoa until many thousands of the organisms are present per low-power field. We have tested three strains of *S. cerevisiae* in the above system. When added daily, all proved capable of supporting the growth of *Giardia*. No yeast derivative that we have tested will substitute for the living yeast in this system. Morphologically, *Giardia* trophozoites from the rabbit (Fig. 1) and chinchilla are indistinguishable. Organisms from both animals average about 8 mc in width and 13 mc in length. Considerable size variation is observed, since many of these organisms are in the process of division.

The culture of *Giardia* trophozoites *in vitro*, described here, is one step in an effort to culture members of this genus axenically. Though there are obvious limitations to the amount of physiological information to be obtained

Fig. 1. Photomicrograph of living *Giardia* trophozoites from the rabbit (× c. 960)

from *Giardia* growing in mixed cultures, it is, nevertheless, possible to investigate a number of characteristics of these organisms, such as morphology, response to chemotherapeutic agents and preservation at low temperatures.

## GENETICS

### Atypical Duffy Blood Group Inheritance and Chromosome Abnormalities

Baikie, Garson and Birrell report in the following communication their discovery of a child who was a mosaic of cells trisomic for a chromosome of the group 17-18 and cells trisomic for a chromosome of the group 13-15. Three cells of a total of 60 were trisomic for both chromosomes. The child had many congenital abnormalities most of which are associated with trisomy 17-18, but microphthalmia and posterior prominence of the heels which occur in trisomy 13-15 were also present.

Table 1 shows the blood group results obtained by one of us (R. T. S.) on blood samples from the father, mother and child.

	ABO	MNSs	Rh	P <sub>1</sub>	Le <sup>a</sup>	Fy <sup>a</sup>	Fy <sup>b</sup>	K	Jk <sup>a</sup>	Lu <sup>a</sup>	Lu <sup>b</sup>
Father	A <sub>1</sub>	MNSs	rh	—	—	+	—	—	—	—	+
Mother	A <sub>2</sub> B	MNSs	Rh <sub>1</sub> Rh <sub>2</sub>	—	—	—	+	—	+	—	+
Child	A <sub>1</sub>	MNSs	Rh <sub>1</sub> rh	+	—	—	+	—	—	—	+

An abnormality of inheritance of the Duffy group was found, in that the father was apparently Fy(a+b-), the mother Fy(a-b+) and the child Fy(a-b+). Thus, while the father appears to carry two Fy<sup>a</sup> genes, the child is Fy(a-).

The present finding is the sixth reported observation of an anomaly of the Duffy blood group inheritance in a

family in which chromosomal abnormality also occurred. The first report was that of Chown, Lewis and Kaita<sup>1</sup>, who found, among 22 families with a mongol child, three with atypical inheritance of the Duffy blood group system. One of the families also showed a possible abnormal inheritance of the ABO system. In all three families a parent of the phenotype Fy(a+b-), whose genotype would ordinarily be assumed to be Fy<sup>a</sup>Fy<sup>b</sup>, had at least one Fy(a-b+) child, while agglutination times indicated that some of the Fy(a+b-) individuals, both parents and children, had only a single dose of Fy<sup>a</sup>. Only one mongol had been recognized in each of the three families studied by Chown *et al.*<sup>1</sup> and the anomalies of blood group inheritance were not found in mongol offspring only. It was thought possible that there may be a genetic factor affecting the expression of a Duffy gene, and perhaps an ABO gene too, which may predispose to non-disjunction of chromosome 21. The same authors<sup>1</sup> have since reported results in 53 more families with a mongol propositus, among whom they found two more families with the same Duffy anomaly. The parents whose red cells had reacted as Fy(a+b-) were later re-tested with a very high-titre incomplete anti-Fy<sup>b</sup> serum and a very weakly positive indirect Coombs reaction resulted. It was then shown that after sensitizing the same red cells with the potent anti-Fy<sup>b</sup> serum an eluate could be obtained which reacted specifically as anti-Fy<sup>b</sup>. It thus appeared that the occurrence of non-disjunction affecting chromosome 21 may be related in some families to either suppression of Fy<sup>b</sup> or the presence of another allele in the Duffy blood group system.

In the present family the father's apparently Fy(a+b-) red cells were carefully re-tested with both complete and incomplete potent anti-Fy<sup>b</sup> sera using three techniques, namely indirect Coombs, agglutination enhancement, and elution. The presence of a small amount of Fy<sup>b</sup> antigen was indicated by each of the three methods used. Our findings are thus analogous to those of Chown *et al.* The important difference is that in the present family non-disjunction involved chromosomes other than chromosome 21 and occurred several times, if not a great many times. The possible association between errors of cell division giving rise to chromosomal abnormalities, and atypical inheritance of the Duffy blood group system, is thus strengthened.

Race and Sanger<sup>2</sup> presented details of six Caucasian families whose Duffy phenotypes could not be explained by the genes Fy<sup>a</sup> and Fy<sup>b</sup> alone. Two of the anomalies relate to one parent who was Fy(a+b-) and did not transmit Fy<sup>a</sup> to some children, while in three others, one parent who was Fy(a-b+) did not transmit Fy<sup>b</sup> as expected. In the sixth Caucasian family living in Texas, a son was found to be Fy(a-b-) and there was no known Negro ancestry. Race and Sanger consider that a Fy(a-b-) condition must be present in Caucasians and that the genetical background is the same as that responsible for the Fy(a-b-) type commonly found in Negroes. The Fy(a-b-) type has also been found in Yemenite and Iraqi families by the same authors.

We have ourselves, like Chown *et al.*, been able to prove that a parent apparently Fy(a+b-) who did not transmit Fy<sup>a</sup> did, in fact, possess some Fy<sup>b</sup> antigen demonstrable only with potent anti-Fy<sup>b</sup> antisera, and using special techniques for its detection. It would appear that the male parent of the present doubly trisomic baby possesses a third Duffy allele or, alternatively, the expression of Fy<sup>a</sup> in the child has been suppressed either as a consequence of the chromosomal abnormalities, or possibly as a concomitant of a special liability to errors of cell division. This last possibility is in accord with the finding<sup>1</sup> of anomalous Duffy inheritance in individuals who were themselves of normal chromosome constitution. The present observations do not allow us to choose between these possibilities, and the study is proceeding

to determine whether the male parent possesses a Duffy antigen which can be shown to be identical with any of the low-frequency blood antigens not at present known to be part of any particular blood group system.

### Mosaicism for Trisomy 17-18 and Trisomy 13-15 in Man

TRISOMY for two chromosomes of the normal chromosome complement has been found in several human subjects. The chromosomes most often involved in these double trisomic states have been the X-chromosome<sup>1,2</sup> and chromosomes of the pairs 13-15<sup>3</sup>, 17-18<sup>1,4</sup> and 21<sup>2,4</sup>. In addition, male subjects with 48 chromosomes have been described in whom one extra chromosome was an X-chromosome, giving the sex chromosome constitution XXY, together with true trisomy for an autosome<sup>5,6</sup>. Hitherto, trisomies 13-15 and 17-18 have not been found in one individual and all the reported cases of double trisomy have apparently had only one cell line.

We recently examined a new-born female child with multiple congenital abnormalities. Chromosome investigations on cultures of peripheral blood leucocytes showed that of 60 dividing cells 39 were trisomic for a chromosome of the pairs 17-18 and 18 were trisomic for a chromosome of the group 13-15. Three cells had 48 chromosomes and were apparently trisomic for a chromosome of both these groups. Buccal mucosal cells were normally chromatin positive. Ten drumsticks were found in 4,000 polymorphonuclear leucocytes in the peripheral blood. It thus seems possible that the child developed from a doubly trisomic zygote of 48 chromosomes and that loss of one or other additional chromosome occurred very early in development. Since no normally constituted cells were found it seems less likely that loss of the additional chromosomes occurred selectively and progressively throughout intra-uterine development.

The child was born at term after a normal pregnancy to a mother aged twenty-six who has had no other pregnancies. The father was aged thirty-one and has one normal child of a previous marriage. Both parents are of normal chromosome constitution. The obvious congenital abnormalities were micrognathia, left microphthalmia, malformed ears, folds of redundant skin and subcutaneous tissue around the neck, dislocation of the left hip, prominent heels, short and dorsiflexed great toes, and partial syndactyly of other toes. In addition, a loud systolic heart murmur was heard and the arms were held in the 'surrender position' with fingers flexed and the index fingers overlapping the others. Most of these abnormalities are associated with trisomy 17-18, the exceptions being microphthalmia and undue prominence of the heels which are commonly found in trisomy 13-15. The child died at the age of six weeks. At autopsy the heart had a high interventricular septal defect and the ductus arteriosus was incompletely closed. The brain was not grossly abnormal apart from an unusually small cerebellum.

The results of blood group examination of the parents and child indicate a possible anomaly of inheritance of

the Duffy group system. These are reported in the previous communication.

## PSYCHOLOGY

### Learning in the Polychaete *Nereis*

THE rapid withdrawal reflex of the polychaetes *Nereis diversicolor*, *N. pelagica* and *Platynereis dumerilii* habituates rapidly to sudden stimuli, such as changes in illumination or mechanical stimuli, but if a foreign stimulus is interpolated in a series of stimulus presentations it is usually followed by greater reactivity to the original stimulus. Responses can sometimes be induced to sudden decreases in light intensity in completely habituated worms by the interpolation of a single tactile stimulus. This process of reflex sensitization has already been described in the polychaete *Meroierella enigmatica*<sup>1</sup>.

Most species of *Nereis* are tubicolous or burrowing animals which come to the ends of their tubes or burrows in order to feed. When feeding they are highly susceptible to attack from a wide variety of predators including fishes, seabirds and crustaceans. Habituation of the rapid withdrawal reflex is usually interpreted as allowing for a compromise between the conflicting needs of the animal: to respond to stimuli caused by predators but not to respond to repeated innocuous stimulation such as shadows caused by passing clouds and seaweed floating in the water<sup>2</sup>. Sensitization may be of biological importance because it enables habituated *Nereis* to react to a previously innocuous stimulus if there is a sudden change in the background stimulation.

Recently it has been shown that either sensitization or similar processes due to repeated stimulation by an unconditioned stimulus (US) can be important in other learning situations. In procedures designed to demonstrate classical conditioning and avoidance learning in *Nereis* the effects of the US have been responsible for modifications in behaviour which might otherwise have been interpreted as associative learning.

Attempts to condition the rapid withdrawal reflex in *N. diversicolor* have been made by pairing a sudden change in illumination (CS), to which *Nereis* habituates, with an electric shock (US), which invariably elicits withdrawal. Controls subjected to the CS alone habituate to it whereas worms subjected to a series of US-CS pairings become more reactive to the CS. However a similar effect can be produced by presenting the US between trials so that it is not paired with the CS (Fig. 1). Furthermore, controls habituating to CS presentations become more reactive if one or more groups of ten consecutive electric shocks are given between trials. Sensitization of the withdrawal reflex by repeated effects of the electric shocks is clearly a more tenable interpretation of these data than one of classical conditioning.

The repeated effects of US stimulation have also been shown to have an important effect in a learning situation

Fig. 1. Percentage of worms *N. diversicolor* reacting to sudden decreases in light intensity (CS) during the following training procedures in which an electric shock has been used as a US: CS-US pairing (continuous line, open circles); US between CS presentations (continuous line, filled circles); CS presented alone (broken line). Standard errors are indicated by the vertical lines.

previously described by the author<sup>3</sup> in which individual *N. diversicolor*, *N. virens* and *P. cultrifera* could learn to avoid an electric shock at the end of a 'Perspex' channel. Worms introduced into the channel crawl rapidly to the end and continue to do so indefinitely as long as they are not punished in any way. However, the behaviour of worms given slight electric shocks, whenever they reach the end of the channel, becomes modified with training so that they either reverse in the channel before reaching the electrodes or refuse to crawl along it. It has now been shown that electric shocks given outside the apparatus are as effective in inducing this modified behaviour as shocks received at the exit of the channel, and that shocks given to worms with no experience in the channel have the same effect on subsequent performance as shocks given in the apparatus. Strong tactile stimulation as a punishment has been shown to have a similar effect. Although an explanation of fatigue can be excluded because trained worms crawl actively outside the apparatus and refusal itself often involves an active reversal by the worm, there is no doubt that the acquired behaviour cannot satisfactorily be regarded as associative learning. It is more likely to be the result of a process similar to sensitization of the reversal response, which is part of the worm's normal tubicolous behaviour<sup>4</sup>, and a mechanism which inhibits forward movement in a confined space, such as a channel or burrow, when the worm is harmfully stimulated.

The importance of sensitization and processes producing similar effects has yet to be evaluated. The effects of these processes can be regarded as learning in the sense that they are modifications of the animal's behaviour as a result of experience but clearly cannot be regarded as manifestations of associative learning. Although similar processes have not been demonstrated in *Nature*, the possibility of widespread sensitization and non-associative learning mechanisms in the lower invertebrates cannot be excluded. Indeed, it has already been suggested<sup>5</sup> that the conditioning claimed in flatworms<sup>6</sup> may be due to the sensitization effects of electric shocks. A study of these processes may be valuable because they may have been important in the evolution of the more refined learning mechanisms of vertebrates and higher invertebrates.

## FORTHCOMING EVENTS

## Tuesday, September 28

INSTITUTE OF MECHANICAL ENGINEERS, GRADUATES' AND STUDENTS' SECTION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.30 p.m.—Prof. R. R. Lathwaite: "Propulsion Without Wheels".

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP AND APPEAL AND TEXTILE CHEMICALS GROUP (at 14 Belgrave Square, London, W.1), at 6.30 p.m.—Mr. D. M. Woodford: "Some Aspects of the Emulsion Polymerization of Vinylidene Chloride and the Properties of its Copolymer".

## Wednesday, September 29

INSTITUTE OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.B.E.-I.M.E. COMPUTER GROUPS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.O.1), at 10.30 a.m.—conference on "Airborne Computers".

AFRICAN STUDIES ASSOCIATION OF THE UNITED KINGDOM (at University College, London, W.O.1), from 10.30 a.m. to 5 p.m.—Symposium on "The Oil Resources of Tropical Africa".

INSTITUTE OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.B.E.-I.M.E. MEDICAL ELECTRONICS GROUP (at 9 Bedford Square, London, W.O.1), at 6 p.m.—Dr. P. M. McGuff: "Treatment of Experimental Animal and Human Malignant Tumours by Laser Radiation".

## Thursday, September 30

ROYAL MICROSCOPICAL SOCIETY, ELECTRON MICROSCOPY SECTION (in the lecture Theatre, Baden-Powell House, Queen's Gate, London, S.W.1), at 1.30 a.m.—Symposium on "The Correct Use of the Electron Microscope in the Study of Biological Specimens".

INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 1 New Cavendish Street, London, W.1), at 5.30 p.m.—"Underwater research" (A Shell film).

TELEVISION SOCIETY (in the I.T.A. Conference Suite, 70 Brompton Road, London, S.W.3), at 7 p.m.—Mr. I. F. MacLennan: "An Introduction to Television-Testing Methods in Television".

## Thursday, September 30—Friday, October 1

INSTITUTE OF BIOLOGY (in the Lecture Hall, Royal Geographical Society, Kensington Gore, London, S.W.7), at 10 a.m. daily—Symposium on "Man-made Lakes".

HUGHES SOCIETY (in the Botany Lecture Theatre, University College, Lower Street, London, W.C.1), at 10.30 a.m. on Thursday and 10 a.m. on Friday—Symposium on "Genetic and Environmental Factors in Human Ability".

## Friday, October 1

ROYAL MICROSCOPICAL SOCIETY, ELECTRON MICROSCOPY SECTION (in the lecture Theatre, Baden-Powell House, Queen's Gate, London, S.W.1), at 0.30 a.m.—Symposium on "Recent Advances in the Technique for Preparing Biological Specimens for Electron Microscopy".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. Frans Sondheimer: "The Influence".

## Monday, October 4

BRITISH BIOPHYSICAL SOCIETY, PHYSICAL BIOCHEMISTRY GROUP (at the school of Pharmacy, Brunswick Square, London, W.O.1), from 11 a.m. to 3.30 p.m.—Meeting on "Light Scattering".

INSTITUTE OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—discussion Meeting on "The Teaching of Mechanics of Machines".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (in the Shell Centre theatre, Shell Centre, London, S.E.1), at 6.30 p.m.—Scientific Film Evening.

## Monday, October 4—Wednesday, October 6

IRON AND STEEL INSTITUTE AND THE INSTITUTE OF METALS (at the Royal Institution, Northumberland Avenue, London, W.O.2)—Joint conference on "Machinability".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN PSYCHIATRY IN THE DEPARTMENT OF PSYCHOLOGICAL MEDICINE—The Secretary, The University, Edinburgh (September 30).

SENIOR LECTURER and a LECTURER (preferably with research experience) IN THE DEPARTMENT OF MATHEMATICS—The Acting Registrar and Clerk to be Governors, Portsmouth College of Technology, Hampshire Terrace, Portsmouth (September 30).

SENIOR LECTURER (with an honours degree) IN MATHEMATICS—The Director of Education, The Polytechnic, Regent Street, London, W.1 (October 1).

ASSISTANT (honours graduate) IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (October 4).

CHAIR OF MATHEMATICS—The Secretary, Royal College of Advanced Technology, Salford 5 (October 4).

RESEARCH ASSISTANT IN THE DEPARTMENT OF PSYCHOLOGY to work with Dr. R. Lynn on a developmental investigation of autonomic reactivity and adaptation—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (October 8).

DEMONSTRATOR (registered member of the veterinary profession) IN VETERINARY MEDICINE in the Royal (Dick) School of Veterinary Studies—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, 8 (October 9).

LECTURER or JUNIOR RESEARCH FELLOW IN PHYSIOLOGY IN THE DEPARTMENT OF PHYSIOLOGICAL SCIENCES, University of Lagos Medical School—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.O.1 (October 10).

RESEARCH ASSISTANT (graduate in engineering or applied mathematics with a higher degree or equivalent research experience) IN THE DEPARTMENT OF CIVIL ENGINEERING, to investigate the possibilities of solving field problems in various branches of applied mechanics, by utilizing finite-element solutions developed for analogous problems in stress analysis—The Registrar, The University, Leeds, 2 (October 11).

LECTURER IN CLINICAL VIROLOGY AT THE UNIVERSITY DEPARTMENT OF INFECTIOUS DISEASES, Rushlin Hospital—The Secretary of University Court, The University, Glasgow (October 15).

LECTURER (with a distinguished academic record) IN THE DEPARTMENT OF PHYSICS, Wollongong University College, University of New South Wales—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 15).

SENIOR LECTURER and a LECTURER (with a Ph.D. degree and postdoctoral research experience) IN ORGANIC CHEMISTRY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 15).

LECTURER IN THE PHYSIOLOGY DEPARTMENT—The Secretary, Royal Free Hospital School of Medicine (University of London), Hunter Street, London, W.O.1 (October 18).

LECTURER/ASSISTANT LECTURER (2) IN COMPUTING (for one post a knowledge of numerical analysis would be an advantage)—The Assistant Registrar (Science), The University of Birmingham, Birmingham, 15 (October 18).

S.R.C. RESEARCH ASSISTANT (with a good honours degree and research experience in experimental physics, and preferably a Ph.D.) IN GEOPHYSICS IN THE DEPARTMENT OF GEOLOGY, for research concerned with properties of rocks and mineral crystals at high temperatures and pressures relevant to deep-seated processes which occur in the earth—The Secretary, University College, Gower Street, London, W.O.1 (October 18).

SENIOR RESEARCH ASSOCIATE and a RESEARCH ASSOCIATE (with research experience in genetics, preferably in the fields of biometrical genetics, population genetics, genealogy or fungal genetics) in the Department of Genetics—The Assistant Registrar (Science), The University of Birmingham, Birmingham, 15 (October 18).

ASSISTANT LECTURER IN CHEMISTRY IN THE DEPARTMENTS OF BOTANY AND ZOOLOGY—The Registrar, The University, Manchester, 13, quoting Ref. 174/65 (October 20).

SENIOR LECTURER or LECTURER IN GEOLOGY WITHIN THE FACULTY OF SCIENCES, Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.O.1 (October 20).

SENIOR LECTURER (ELECTRONICS) (graduate with considerable industrial or other postgraduate experience in semiconductor applications) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING; and a LECTURER (graduate with industrial or other postgraduate experience, preferably with a special interest in hydrology) IN THE DEPARTMENT OF CIVIL ENGINEERING, University College, Nairobi (University of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.O.1 (October 25).

SENIOR LECTURER or LECTURER IN MATHEMATICS at the University of Basutoland, Bechuanaland Protectorate and Swaziland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.O.1 (October 25).

LABORATORY TECHNICIAN or SENIOR LABORATORY TECHNICIAN IN THE DEPARTMENT OF BIOCHEMISTRY AND NUTRITION—The Registrar, University of New England, Armidale, New South Wales, Australia (October 25).

READER IN INFORMATION PROCESSING; and a READER IN COMPUTER SCIENCE in the Institute of Computer Science—The Academic Registrar, University of London, Senate House, London, W.O.1 (October 29).

SENIOR LECTURER and a LECTURER IN PHYSICS at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 29).

CHAIR OF ORGANIC CHEMISTRY—The Registrar, University of Kent at Canterbury, Canterbury (October 30).

SENIOR DEMONSTRATOR (with an honours degree in science with biochemistry as a major subject) IN BIOCHEMISTRY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 30).

LECTURER IN PLANT PHYSIOLOGY—Prof. O. P. Whittingham, Botany Department, Imperial College, Prince Consort Road, London, S.W.7 (October 31).

LECTURER or SENIOR LECTURER (specialized in mineralogy and geochemistry); an ASSISTANT LECTURER (with basic training in geology and a special knowledge of geomorphology); and a DEMONSTRATOR (with a special knowledge of mineralogy and petrology) IN THE DEPARTMENT OF GEOLOGY AND MINERALOGY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (October 31).

LECTURER (with an active interest in educational sociology or educational philosophy) IN EDUCATION at Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

READER and a SENIOR LECTURER IN MICROBIOLOGY; and a READER and a LECTURER IN ZOOLOGY at the University of Adelaide, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, October 31).

HEAD (specialist in plant breeding) OF THE DEPARTMENT OF PLANT SCIENCE, Institute of Animal Science, Havana, Cuba—The Chargé d'Affaires, The Cuban Embassy, 22 Mount Street, London, W.1 (November 1).

POST-DOCTORAL RESEARCH ASSISTANT (BIOCHEMIST) to take over and develop a programme of research on the effects of gene suppressor mutations on protein synthesis in yeast—The Administrator, Botany School, The University, Oxford (November 1).

LECTURER (with a degree in engineering or in science or an equivalent qualification, and preferably practical experience in the mineral industry) IN MINERAL TECHNOLOGY, University of Otago, Dunedin, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or the Registrar of the University (New Zealand and London, November 30).

SENIOR LECTURER (with a good honours degree in engineering or science with several years of research and/or industrial and/or teaching experience) IN THE DEPARTMENT OF CHEMICAL ENGINEERING, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 30).

**ASSISTANT EXPERIMENTAL OFFICER** (with a pass degree, H.N.C. or equivalent, or if under 22, 2 G.O.R. "A" levels or maximum) in the Department of Radiobiology, for work involving the assay, synthesis and study of the metabolism of isotopically labelled compounds—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Berkshire, quoting Ref. 64/15.

**ASSISTANT EXPERIMENTAL OFFICER** (with a suitable degree, Dip. Tech., H.N.C. (or equivalent) or, if under age 22, two G.O.R. "A" levels in scientific subjects, a sound knowledge of physics and a keen interest in astronomy) for research into the physics of stars and galaxies—The Secretary, Royal Observatory, Edinburgh, 9.

**ASSISTANT LECTURER IN THE DEPARTMENT OF MOLECULAR BIOLOGY** to participate in the work of an M.R.C. Research Group on bacterial enzyme variation, involving the application of biochemical, biophysical and chemical techniques to the study of the specific control of enzyme biosynthesis in bacteria—Prof. M. R. Pollock, Department of Molecular Biology, University of Edinburgh, The King's Buildings, Edinburgh, 9.

**ASSISTANT TRIALS OFFICER** (with training in botany or agriculture and a recognised degree or national diploma) at the NATIONAL INSTITUTE OF AGRICULTURAL BOTANY TRIALS OFFICER, Seale-Hayne, Newton Abbot, Devon, for work on small-scale field trials on new varieties of farm crops—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

**CHEMISTS** (with a good honours B.Sc. degree and preferably of Ph.D. standing) to work in fields such as relation between structure and properties in polymeric materials, modification of polymer properties, high temperature resistant surface coating agents, and the application of reverse osmosis to the desalination of water and to non-aqueous systems—The Director, Arthur D. Little Research Institute, Inverkeithing, Midlothian.

**ENTOMOLOGIST (THESE)** (national of the United Kingdom or the Republic of Ireland, with an honours degree in natural science, entomology or zoology) in Zambia (Northern Rhodesia), to plan and assess control measures involving surveys of fly incidence and its relation to local ecological factors, to determine the most suitable methods of control, and to supervise Tsetse Control Staff—The Appointment Officer, Ministry of Overseas Development, Room 301, Mand House, Stag Place, London, S.W.1, quoting Ref. BO 517/132/01.

**GRADUATE BIOCHEMIST or CHEMIST** to assist in the study of enzymes occurring in cerebral tumours—The Secretary, Institute of Psychiatry, The Maudsley Hospital, Denmark Hill, London, S.E.5.

**HOSPITAL BIOCHEMIST** in the Area Laboratory—The Secretary, Whipps Cross Hospital, London, N.11.

**JUNIOR RESEARCH OFFICER or RESEARCH OFFICER** (preferably post-doctoral) in the DEPARTMENT OF PHYSICS to assist in the analysis of rocket and satellite data—The Registrar, University College of Wales, Aberystwyth.

**LECTURER IN INORGANIC CHEMISTRY**—The Academic Registrar, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

**LECTURER** (preferably with a special interest in thermodynamics and applied mechanics or strength of materials) in MECHANICAL ENGINEERING at the University of the West Indies (Trinidad)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

**POST-DOCTORAL FELLOW IN ORGANIC CHEMISTRY** to work in collaboration with Dr. N. A. J. Rogers, on a study of the protonation of conjugated enolic derivatives—The Secretary, University of Lancaster, Bailrigg House, Lancaster.

**RESEARCH ASSISTANT** (with a qualification, not necessarily a degree, in physics and/or chemistry) in the DEPARTMENT OF INORGANIC AND STRUCTURAL CHEMISTRY, for duties which will include the operation of electronic equipment for X-ray crystallography—Dr. M. R. Truter, School of Chemistry, The University, Leeds, 2.

**SENIOR LECTURER** (preferably with interests in mathematical logic or numerical analysis or control theory) in the DEPARTMENT OF MATHEMATICS—The Registrar, Hatfield College of Technology, Hatfield, Hertfordshire.

**SOIL SURVEYOR** (honours graduate in natural science, agricultural science, or agriculture, with experience in soil surveying, preferably in the tropics) in the REGIONAL RESEARCH OFFICER, Trinidad (University of the West Indies)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

Ministry of Overseas Development. Overseas Development: The Work of the New Ministry. (Cmd. 2786.) Pp. 74. (London: H.M. Stationery Office, 1965.) 5s. 6d. net.

Bulletin of the British Museum (Natural History). Zoology. Vol. 12, No. 8: Acanthodrilidae and Budrilidae (Oligochaeta) from Ghana. By B. W. Sims. Pp. 233-311. 10s. Vol. 12, No. 9: The Ophid Fishes of Lake Nabugabo, Uganda. By P. H. Greenwood. Pp. 313-357. 15s. Vol. 12, No. 1: Primitive Cryptostigmatid Mites from Rhododendron Forests in the Nepal Himalayas. By J. G. Shearer. Pp. 1-35. 18s. The Ophiote Mosquitoes of the Indomalayan Area. Part 6: Genus *Aedes* Meigen. Subgenus *Stegomyia* Theobald (Groups A, B and D). By P. F. Mattingly. Pp. 67. 24s. (London: British Museum (Natural History), 1965.)

Proceedings of the British Ceramic Society, No. 4 (July 1965): Load-bearing Brickwork. Pp. 121. (Stoke-on-Trent: British Ceramic Society, 1965.) 25s.

Royal Observatory Bulletin. No. 95: Photometry of the Cluster NGC 6522. By S. V. M. Clube. Pp. B383-B405+2 plates. 4s. 6d. net. No. 96: Time and Latitude Service 1964, July-September. Pp. 1+B371-B385. 2s. net. (London: H.M. Stationery Office, 1965.)

Camlab (Glaxo). Ltd. Camlab Guide to Thin-layer Chromatography. Second edition, including Column Chromatography and Electrophoresis. Pp. 80. (Cambridge: Camlab (Glaxo), Ltd., 1965.)

The Wildfowl Trust. Sixteenth Annual Report 1963-64. Illustrated by Peter Scott. Pp. 136+22 photographs. (Brimbridge, Gloucestershire: The Wildfowl Trust, 1965.)

National Society for Clean Air. Clean Air Year Book, 1965-66. Pp. 120. (London: National Society for Clean Air, 1965.) 5s.

Commonwealth Agricultural Bureaux. Technical Communication No. 16: The Meat Production Potential of Wild Animals in Africa—a Review of Biological Knowledge. By Leo M. Talbot, W. J. A. Payne, H. P. Ledger, Lorna D. Verdcourt and Martha H. Talbot. Pp. vi+42. (Farnham Royal, Bucks: Commonwealth Agricultural Bureaux, 1965.) 12s. 6d.

European Ceramic Association. Report of a Meeting to consider Particle Size Measurement arranged by the Basic Science Committee, held at the British Ceramic Research Association, Stoke-on-Trent, Friday and Saturday,

1st and 2nd November, 1963. Pp. 20. (Stoke-on-Trent: The British Ceramic Society, 1965.) 5s.

Oiba (A.R.L.), Ltd. Technical Notes (July, 1965): Analite in 1 Restoration of Roman Mosaics. Pp. 12. (Dunford: Oiba (A.R.L.), Ltd., 1965.)

Forestry Commission. Forty-fifth Annual Report of the Forestry Commission for the year ended 30th September, 1964. Pp. 67+8 plates. 2s. 6d. net. Bulletin No. 57: Experiments on Nutrition Problems in Forest Nurseries. Vol. 1: Pp. xi+251+25 plates. 50s. net. Vol. 2: Pp. v+204 20s. net. Forest Record No. 53: Studies on the Mineral Nutrient Status of Heather, *Calluna vulgaris*. By J. R. Aaron. Pp. 23. 2s. net. Forest Record No. 55: Death of Pedunculate Oak and Variations in Annual Radial Increments Related to Climate. By O. W. T. Young. Pp. 16. 2s. net. Library Review, No. 1, March 1965. Pp. 27. (London: H.M. Stationery Office, 1965.)

### Other Countries

Bulletin of the American Museum of Natural History. Vol. 129, Article Hybridization in the Flickers (Colaptes) of North America. By Lester Short, Jr. Pp. 307-428. (New York: American Museum of Natural History, 1965.) 2 dollars.

Republic of South Africa: Department of Commerce and Industries Division of Sea Fisheries Investigation Report No. 51: South Africa Contribution to the International Indian Ocean Expedition. (3): Cru. 251 of R/S *Afronius II* during June/July 1961. By R. W. Rand. A Preliminary Report on the Planktonic Crustaceans. By A. de Deel and F. J. Mombbeck. (Reprinted from *Oceanus and Industry*.) Pp. (Pretoria: Government Printer, 1965.)

Food and Agriculture Organization of the United Nations. World Food Program Studies, No. 5: The Role of Multilateral Food Aid Programs. J. Jan Demau. Pp. v+28. (Rome: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1965.) 5s.; 1 dollar.

Organization for Economic Co-operation and Development: European Nuclear Energy Agency. O.N.E.A. High Temperature Reactor Project "Dragon"—Sixth Annual Report, 1964-1965. Pp. 120. (Paris: Organization for Economic Co-operation and Development, European Nuclear Energy Agency; London: H.M. Stationery Office, 1965.)

Annals of the New York Academy of Sciences. Vol. 124, Part 1: Autoimmunity—Experimental and Clinical Aspects. By A. Abadie and 86 other authors. Pp. 1-412. Vol. 124, Part 2: Autoimmunity—Experimental and Clinical Aspects. By J. R. Anderson and 87 other authors. Pp. 413-890. (New York: New York Academy of Sciences, 1965.)

Bulletin of the Florida State Museum—Biological Sciences. Vol. 9, No. 6: The Pleistocene Follies of Florida. By Bjorn Kurten. Pp. 215-277. Vol. 9, No. 7: The Cranial Anatomy of the Hog-nosed Snake (*Heterodon*). By W. G. Weaver, Jr. Pp. 275-304. (Gainesville: Florida State Museum, 1965.)

Southern Rhodesia. Report of the Trustees of the Museums of the Nations. Southern Rhodesia for the year ending December, 1964. Pp. 25. (Salisbury: National Museums of Southern Rhodesia, 1965.)

Australia: Commonwealth Scientific and Industrial Research Organization. Land Research Series, No. 14: Land Use in the Murrumbidgee-Kalbarri Area, Territory and Papua and New Guinea. Papers by J. A. Mabbitt, P. O. Heyliger, B. M. Scott, J. G. B. Smith, A. Fitzpatrick, J. R. MacAlpine and B. Pullen. Pp. 123+12 plates. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1965.)

World Health Organization. Public Health Papers, No. 26: Domestic Accidents. By Prof. B. Maurice Backlund. Pp. 137. (Geneva: World Health Organization; London: H.M. Stationery Office, 1965.) 6 Sw. franc. 10s.; 2 dollars.

Metropolitan Life Insurance Company. Statistical Bulletin, Vol. (May 1965): Marriages Continue to Increase. Births in Plural Confinement Perinatal Mortality Decreasing. More Than 5,000 Drowning a Year in the United States. Pp. 12. (New York: Metropolitan Life Insurance Company, 1965.)

Proceedings of the California Academy of Sciences—Fourth Series Vol. 22, No. 12 (July 23, 1965): Studies on the Atlantic American Pipefishes with Descriptions of New Species. By Earl S. Herald. Pp. 363-376. Vol. 22, No. 1 (July 23, 1965): The Brachyuran Decapod Crustaceans of Offington Island. By John B. Garth. Pp. 1-46. Vol. 22, No. 2 (July 23, 1965): On the Identification of *Schizoglyphus californiensis* Conrad, a Californian Pliocene Gastropod. By W. O. Addicott. Pp. 47-68. (San Francisco: California Academy of Sciences, 1965.)

Forest Research in India, 1961-62. Part 1: The Forest Research Institute Dehra Dun. Pp. ii+181. Rs. 2.90; 6s. 10d. Forest Research in India, 1963-64. Part 1: The Forest Research Institute, Dehra Dun. Pp. ii+16. Rs. 3.75; 8s. 9d. (Delhi: Manager of Publications, 1965.)

Records of the Australian Museum, Vol. 26, No. 12 (4th December, 1964): Metrical Features of Aboriginal Crania from Coastal New South Wales Australia. By L. Freedman. Pp. 309-323. (Sydney: The Australian Museum, 1964.) 4s.

Mitteilungen aus der Biologischen Bundesanstalt für Land- und Forstwirtschaft, Berlin-Dahlem. Heft 115 (Juni 1965): Deutsche Pflanzen schutz-Tagung der Biologischen Bundesanstalt für Land- und Forstwirtschaft in Wiesbaden, 12-18 Oktober 1964. Pp. 236. (Berlin-Dahlem: Biologische Bundesanstalt für Land- und Forstwirtschaft, 1965.) 44 D.M.

National Academy of Sciences—National Research Council. Publication 1276: Geochronology of North America. (Nuclear Science Series—Report No. 41.) Pp. v+816. (Washington, D.C.: National Academy of Sciences—National Research Council, 1965.) 6 dollars.
